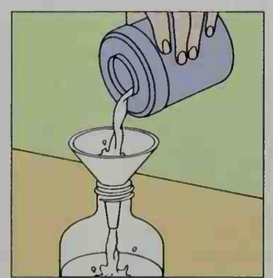
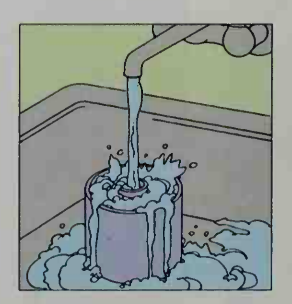
How to develop film

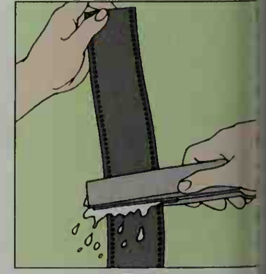
To develop film, you need three main chemical solutions. The *developer* converts the exposed silver salts on the film into metallic silver. The *stop bath* halts the action of the developer. The *fixer,* also called *hypo,* dissolves the unexposed silver salts so they can be washed away.

WORLD BOOK illustration by Robert Ke



Wind the film onto the reel of the developing tank. Then place the reel in the tank and close the lid. You must work in total darkness until the film is inside the covered tank.





Measure the developer and bring it to the correct temperature, as specified in the instructions that come with the film. Next, pour the liquid into the tank and begin to time the proces

Agitate the tank at regular intervals during development. When the developing time is up, pour out the developer and add the stop bath. Then drain the tank and pour in the fixer.

Rinse the film with running water or a washing agent. Unwind the film from the reel of the tank and remove excess water with a squeegee. Finally, hang the film to dry in a dustfree area.

w to judge a negative

Negatives should have good contrast among tones, plus detail in both highlight and shadow areas. If a negative is mostly dark and lacks detail in the highlight areas, it may be *overexposed.* A negative that has harsh highlights and few details in the shadow areas is probably *underexposed.*

WORLD BOOK photos

rmal negative

Overexposed negative

Underexposed negative

ould be clearly labeled with the name of its contents. developed film must not be exposed to light, and so ompletely dark room or a lightproof *changing bag* also needed.

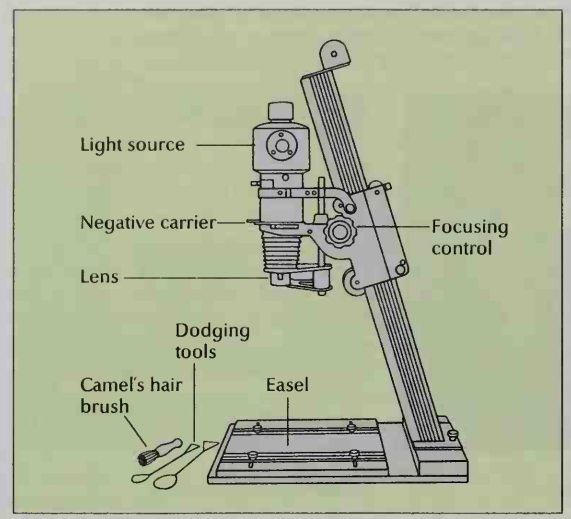
The developing process has five basic steps. First, a emical called a *developer* converts the exposed silver ts on the film's emulsion into metallic silver. The acn of the developer is then stopped either by water or a chemical solution known as a *stop bath.* In the third p, a chemical called a *fixer,* or *hypo,* dissolves the unosed silver salts so they can be washed away. The er also contains a special hardening agent that makes emulsion resistant to scratches. Next, the film is shed to remove the unexposed salts and the remain- chemicals. In the final step, the film is dried. The deloped film is now a negative on which a visible, pernent image has been recorded.

If you wish to process film yourself, first darken the om or use a changing bag and remove the film from spool. Then wind the film onto a reel that fits inside a htproof *developing tank.* This tank is designed so that uids can be poured into or out of it without removing lid. After the film is in the developing tank, you can rk on it in the light.

Different types of developers and fixers are used for rious kinds of film. The instructions provided with the n specify the type of solutions to use and the correct nperatures for the best results. Temperature is particrly important for the developer. Negatives will be erdeveloped if the developer is too warm, or underveloped if it is too cold. The instructions also tell you w long to treat the film with the various solutions. To sure proper development, each operation should be ned exactly.

After the developer has been heated or cooled to the rrect temperature, pour the chemical into the develing tank. Then *agitate* the tank for 30 seconds by reatedly turning it upside down and back again in a ady movement. Agitation keeps a fresh supply of the veloper in contact with the film so the image on the n's surface develops evenly. Next, rap the tank on a hard surface to dislodge any air bubbles. Air bubbles can leave spots on the film. While the developer is in the tank, the film should be agitated at half-minute or one-minute intervals after the first 30 seconds.

When the developer has been in the developing tank for the specified time, pour it out and fill the tank with either running water or a stop-bath solution. Agitate the tank vigorously for about 10 seconds, and then drain it and pour in the fixer. After the fixing bath, which may last from 2 to 10 minutes, rinse the film with water or a special washing agent. Such an agent reduces the washing time from about 20 minutes to about 5 minutes. The film should then be treated with a wetting agent to remove any water spots.



To dry the film, unwind it from the reel in the developing tank and hang it in a dust-free area. A clip or a clothespin should be attached to the lower end of the film to prevent the film from curling. As soon as the film has dried completely, cut it into strips of from four to six negatives. Store the strips of negatives in film envelopes in a clean, dry place. Negatives can easily be scratched or bent, and so you should handle them by the edges.

Printing black-and-white photographs is a process similar to making negatives. Printing paper is coated with an emulsion containing silver salts. During the printing process, light exposes the salts and forms a latent image on the printing paper. The paper must be developed before it can produce the visible image that will appear in the finished print.

To develop the printing paper, repeat the steps used in developing film. However, the paper is generally placed in open printing trays rather than in a developing tank, and different chemicals are used. To protect the latent image, you should work under a *safelight.* This kind of light illuminates the work area but does not expose the printing paper.

There are two principal methods of printing black-and-white photographs, *contact printing* and *projection printing.* Each process requires special equipment and produces a different type of print.

Contact printing is the simplest method. To make a

WORLD BOOK illustration by Robert Keys

An enlarger, the basic instrument used in projection printing, projects the image in a negative onto printing paper. Light passes through the negative and exposes the paper in the easel.

contact print, place the strips of negatives on a sheet of printing paper and cover them with a piece of glass. Use a *printing frame,* a *printing box,* or some similar device to hold the negatives and paper in place. Shine a light through the glass for a few seconds, and then remove the paper and develop it. If the print is too dark, repeat the process with a shorter exposure time. If the print is too light, use a longer exposure.

Contact printing is a quick, inexpensive way to preview photographs before making the final prints. Contact prints are the same size as the negatives, and so you can print an entire roll of film in one operation. For example, a 36-exposure roll of 35-millimeter film can be contact printed on a sheet of paper that measures 8 by 10 inches (20 by 25 centimeters).

Projection printing, also called *enlarging,* produces photographs that are larger than their negatives. In projection printing, the negative is placed in a device called an *enlarger.* The enlarger projects the negative image onto printing paper in much the same way as a slide projector throws an image onto a screen. The image on the printing paper is larger than that on the negative. The size of this projected image depends on the distance between the negative and the paper. The greater the distance, the larger the image.

Enlargers have three basic parts, the *head,* the *baseboard,* and a rigid column that supports the head and is connected to the baseboard. The head contains a lens, a carrier for the negative, and a source of light. Like many cameras, the enlarger head also has a focusing control and an adjustable aperture. An easel on the baseboard holds the printing paper. During the enlarging process, the lens focuses the negative image on the printing paper, and light from the light source passes through the negative and exposes the paper.

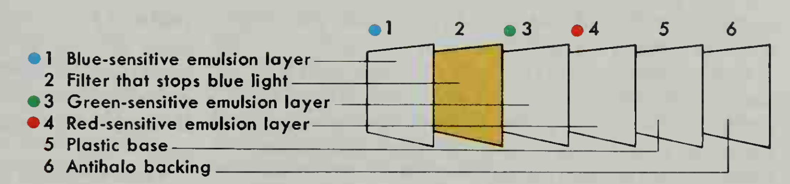
The head of an enlarger can be raised or lowered to change the size of the image on the printing paper. This flexibility in size enables you to change the composition of the picture as well as enlarge the size of prints. By making the image larger than the intended print, you can crop undesirable areas along the edges and reposition the elements of the picture.

Before using an enlarger, you should clean the negative carefully with a camel's-hair brush or an aerosol device. Particles of dust on a negative may show up as white spots on the finished prints. Place the negative in the carrier, turn on the enlarger light, and focus the image on a piece of plain white paper or cardboard in the easel. Next, adjust the aperture. For most prints, you should at first set the aperture at a medium f-stop, such as f/8. After the image has been focused and framed, turn off the enlarger light and the light in the work area and turn on the safelight. Then insert a sheet of printing paper into the easel.

The next step in the enlarging process is to determine the proper exposure time for the print by making *test strips.* Test strips are portions of a print that have been exposed for different amounts of time, generally ranging from 10 seconds to 50 seconds. After the test strips have been developed, you can decide which of the exposure times produced the best result. If all the test strips appear too light, open up the enlarger lens by two f-stops and make another set of strips. If the test strips are all too dark, close down the lens by two f-stops and repeat the procedure.

If only one area of the print turns out too light, you can darken the area by *burning in* the print. In this technique, a piece of cardboard with a small hole in it is held over the area to be darkened. Light passes through the hole in the cardboard and exposes the area, which then becomes darker. If an area of the print is too dark, it can be lightened by means of *dodging.* This procedure involves covering the dark area with a special dodging tool or a cardboard disk during part of the exposure time. The covered area will appear lighter in relation to the fully exposed parts of the print.

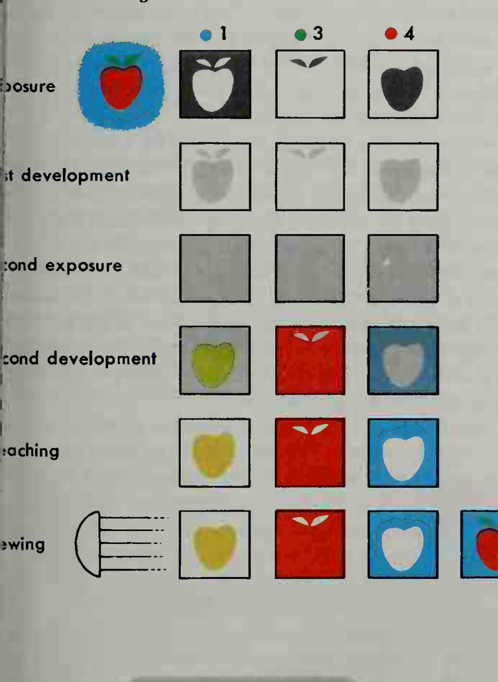
Overall contrast in prints is determined largely by the type of printing paper used. Printing papers are graded by number from 0 to 6 according to the degree of contrast produced in the prints. The higher the number, the greater the degree of contrast. A high-contrast paper, such as No. 4, is generally used to print a normal range of tones from a negative that has little contrast. Paper No. 1, a low-contrast paper, may be used to reduce the contrast in a negative that has extreme light and dark tones.



Some papers contain different grades of contrast. These *multicontrast papers* require different colors of light to produce each grade. You can change the color of the enlarger light by placing a colored printing filter over the lens.

In addition to contrast, printing papers vary in several characteristics that affect the appearance of prints. One of these characteristics is tone. In a photograph printed on *warm-toned paper,* the color black is reproduced as brown. On *cold-toned paper,* black appears blue. Another feature of printing papers is surface, which ranges from *matte* (dull) to glossy.

Developing color film involves the same basic procedures as black-and-white developing. However, the

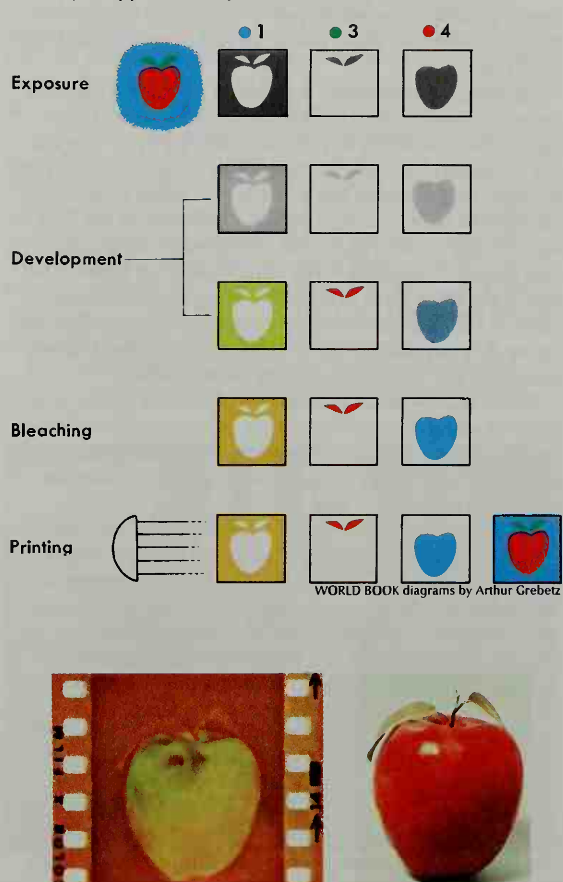


H w color film works

C or film consists of six layers: (1) an e ulsion that records blue, (2) a yellow fil- t that absorbs excess blue light, (3) an e ulsion that records green, (4) an emul- s n that records red, (5) a plastic base that s ports the emulsions, and (6) an *antihalo* b king that absorbs excess light.

H w color slides are made

C or slides are made from color reversal film. After exposure, t film contains images of the blue, green, and red areas of the s ject. The film then goes through two development proc- e es. The first development changes the exposed silver salts to r tallic silver. A negative silver image forms in each layer of the f n. Then the film is re-exposed so that the remaining silver s ts can be developed. During the second development, col- c d dyes form around the silver images on the film. The silver i hen bleached out of each image, leaving transparent film in t se areas. In the developed film, a yellow dye surrounds the i age made by blue light. A *magenta* (purplish-red) dye sur- r nds the image made by green light. A *cyan* (bluish-green) c surrounds the one formed by red light. When the film is r de into a slide and projected, each dye holds back light of its c nplementary color, and the original colors of the subject ap- p ar on the viewing screen.



Color slide

How color prints are made

Color prints are made from color negative film. After exposure, the film contains images of the blue, green, and red areas of the subject. During development, the exposed silver salts produce a metallic silver image in each layer of the film. A colored dye forms over each image. The silver is then bleached out, leaving only the dye. In the negative, a yellow dye covers the image made by blue light. A magenta dye covers the image made by green light. A cyan dye covers the one formed by red light. These colors are hard to see because the negative has an overall orange tint that improves the color quality of prints. When the negative is printed, each dye holds back light of its complemen- tary color. The yellow dye absorbs blue light and lets red and green light pass through. The magenta dye absorbs green and lets blue and red through. The cyan dye absorbs red and lets blue and green go through. In this way, the original colors of the subject appear in the print.

Negative film

Color print

chemical processes in color developing are much more complicated. To understand these processes, you need to know some of the basic principles of color.

Color depends chiefly on light. Although most light looks white to the eye, it is actually a mixture of three *primary colors*—blue, green, and red. Any color can be produced by blending these three colors of light. See Color (Mixing colored lights).

Color film contains three layers of emulsions. These emulsions are similar to the emulsion on black-and-white film. But in color film, each of the emulsions is sensitive to only one of the primary colors of light. During exposure, the first emulsion reacts only to blue light, the second emulsion only to green light, and the third only to red light.

When color film is exposed, light strikes the first emulsion and forms an image on the blue areas of the scene. The light then passes through the second emulsion, forming an image of the green areas. Finally, the light goes through the third emulsion and records an image of the red areas. Three latent images are thus recorded on the film.

The developing process changes color film in two main ways. First, the developer converts the exposed silver salts on the emulsions into metallic silver. The silver image produced on each layer of emulsion represents the color of light—blue, green, or red—that exposed the emulsion.

Second, the developer activates a substance called a *coupler* in each emulsion. Couplers unite with chemicals in the developer to produce colored dyes. The colors of the dyes are the *complements* (opposite colors) of the light that exposed the emulsions. Yellow is the complement of blue, and so a yellow dye forms in the first layer. In the second layer, the dye is *magenta* (purplish-red) because magenta is the complement of green. The dye in the third layer is *cyan* (bluish-green), the complement of red. Complementary colors are used as dyes because they reproduce the original colors of the subject when the film is processed into photographs.

Both color reversal film, which produces slides, and color negative film, which makes prints, record colored images in the same way. However, different materials and slightly different procedures are used to develop each type of film.

Color reversal film requires two different developers. The first developer changes the exposed silver salts on the film into metallic silver. The film is then reexposed or treated with a chemical agent so that the remaining silver salts can be developed. The second developer activates the couplers in the emulsions, causing colored dyes to form around the silver image in each emulsion layer. After the silver has been bleached out of the images, the images remain as transparent areas on the film. The developed film, called a *positive,* can be cut into separate pictures and mounted as slides.

On a slide, each area of the subject is transparent in one of the emulsion layers. In each of the other two layers, the area has a complementary color different from that of its original color. For example, the image of a blue sky would be transparent in the first emulsion layer. The image would be magenta (the complement of green) in the second layer and cyan (the complement of red) in the third layer. When light passes through the slide, each dye acts as a filter on a primary color. The magenta layer holds back green light, and the cyan layer holds back red light. As a result, only blue light passes through the transparent area of the slide, and the sky appears blue.

Color negative film is treated with only one developer. The developer converts the exposed silver salts into metallic silver and activates the dye couplers at the same time. After the developing procedure, each area of the subject appears on a layer of emulsion in a color complementary to the original color. For example, a blue object would be recorded as a yellow image on the first emulsion layer, and a green one would appear as a magenta image on the second layer. The colors of the images are reversed to their original shades during the printing process.

Printing color photographs involves the same chemical processes as those in the development of color film. Like color film, color printing paper has three layers of emulsions, each of which is sensitive to one of the primary colors of light. During printing, the yellow, magenta, and cyan dyes on the negative hold back light of their complementary colors—that is, each dye filters out one of the primary colors. Thus, the colors of light that expose the printing paper are the opposite of those that exposed the film. When the paper is developed, couplers in the emulsion layers form dyes that reproduce the colors of the subject.

Certain features of color prints can be changed by some of the same techniques used in black-and-white printing—adjusting the exposure, cropping, burning in, and dodging. In addition, the *color balance* of the prints can be adjusted by placing color filters over the enlarger lens. These filters, which are tinted in various shades of yellow, magenta, and cyan, reduce the intensity of the corresponding primary colors in the print. If the blue tones in the print are too strong, for example, you should put a yellow filter on the enlarger lens and repeat the printing procedure.

Color prints can be made from color slides as well as from color negatives. The same basic printing procedures are used in making slides and negatives. However, the effects of exposure are reversed with slides, which contain positive images. In printing from negatives, for example, a longer exposure makes a print darker. But in printing from slides, the same exposure time makes a print lighter. The effects of color filters are also reversed in making prints from slides. Strong colors in such prints are balanced by using filters of the same colors rather than of complementary colors.

Instant processing. Instant film produces prints in from 15 seconds to 8 minutes, depending on the type of film that is used. When the exposed film is taken out of an instant camera, it is covered by a lightproof sheath. This sheath can be either a sheet of paper or an *opaque* (nontransparent) layer of chemicals. The sheath serves as a kind of darkroom for the processing of the film. If the film has a paper sheath, the sheet of paper is peeled from the print after the specified developing time. If the film has a chemical sheath, the print is finished when the

que layer turns completely transparent.

nstant prints are processed in much the same way as tact prints. The chief difference between the two cedures is that the negative and the positive of an in- t print are developed at the same time rather than in arate stages.

nstant black-and-white film contains layers of nega- and positive emulsions, with a packet of jellylike de- oping chemicals between the layers. After exposure, film passes through a pair of steel rollers in the cam- The pressure of the rollers causes the packet to st, releasing the developing chemicals. The chemi- immediately convert the exposed silver salts on the negative layer into metallic silver. Within a few seconds, the unexposed salts move to the positive layer. There, they are changed into silver, forming a positive image on the print.

Instant color film has layers of colored dyes in addition to negative and positive emulsions and a packet of developing chemicals. When the chemicals are released, they develop the silver salts and activate the colored dyes at the same time. An image in colors complementary to those of the subject forms on the negative layer of emulsion. Then the image is transferred onto the positive emulsion layer, where the colors are reversed to the original ones.

History

arly developments. The ancient Greek philosopher stotle observed that light passing through a small e in the wall of a room formed an upside-down ge of an object. However, this characteristic of light not used to construct a camera until about A.D. 0, in Italy. The first crude camera, called a *camera ob- ra* (dark chamber), consisted of a huge box with a opening in one side that admitted light. On the op- site side of the box, the light formed an inverted ge of the scene outside. The camera obscura was je enough for a person to enter, and it was used efly by artists as a sketching aid. They traced the out- of the image formed inside the box and then col- d the picture. See **Camera obscura**.

camera obscura could only project images onto a een or a piece of paper. Scientists sought a way to ke the images permanent. In 1727, a German physi- t named Johann H. Schulze discovered that silver salts n dark when exposed to light. About 50 years later, l Scheele, a Swedish chemist, showed that the nges caused in the salts by light could be made per- nent by chemical treatment. However, these discov- es were not used for photography until the 1830's.

Meanwhile, a French inventor named Joseph Nicéphore Niépce found a way to produce a permanent image in a camera obscura. In 1826, he coated a metal plate with a light-sensitive chemical and then exposed the plate in the camera for about eight hours. The resulting picture, showing the view from Niépce's window, was the world's first photograph.

Niépce's technique was perfected during the 1830's by the French inventor Louis Daguerre. Daguerre exposed a sheet of silver-coated copper, developed the image with mercury vapor, and then "fixed" it with table salt. His pictures, called *daguerreotypes,* required a relatively short exposure of 15 to 30 seconds and produced sharp, detailed images. See **Daguerreotype**.

In 1839, the same year Daguerre patented his process, a British inventor named William H. Fox Talbot announced his invention of light-sensitive paper. This paper produced a negative from which positive prints could be made. Fox Talbot's friend, the astronomer Sir John Herschel, called the invention *photography.* Herschel suggested the use of sodium thiosulfate (hypo) as a fixing agent. Both Daguerre and Fox Talbot then began using this chemical in their processes.

Fox Talbot's paper prints, which were called *talbotypes* or *calotypes,* did not contain images as sharp as

The Gernsheim Collection, University of Texas at Austin

e first photograph, taken in 1826 by Joseph Nicéphore pce, a French physicist, shows a view from his window. He osed a light-sensitive metal plate for about eight hours.

Louis Daguerre, Société Française de Photographie, Paris

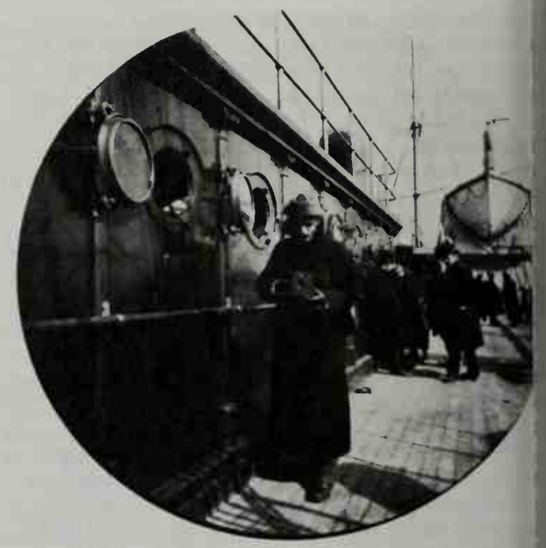
The daguerreotype was the first popular form of photography. It required a relatively short exposure. The earliest surviving daguerreotype, *above,* was made in 1837.

those of daguerreotypes. But the negative-to-positive process of making photographs had two important advantages. It produced many prints from one exposure, and the pictures could be included in books, newspapers, and other printed materials. See **Talbotype**.

In addition to the new developing and printing processes, photography was greatly improved during the 1840's by the introduction of specialized lenses. A Hungarian mathematician named Josef M. Petzval designed two types of lenses, one for making portraits and the other for landscape pictures. The portrait lens admitted much more light than previous lenses had and so reduced the exposure time to a few minutes. The landscape lens produced sharper pictures of large areas than previously had been possible.

The beginnings of modern photography. During the second half of the 1800's, scientists further improved photographic processes and the design of cameras. These advances enabled photographers to experiment with the artistic possibilities of photography.

Technical improvements. In 1851, a British photographer named Frederick S. Archer introduced a photographic process that greatly reduced exposure time and improved the quality of prints. In Archer's process, a glass plate was coated with a mixture of silver salts and an emulsion made of a wet, sticky substance called *collodion*. After being exposed for a few seconds, the plate was developed into a negative and then treated with a fixing agent. The collodion had to remain moist during exposure and developing, and so a photographer had to process pictures immediately after taking them. Many photographers traveled in wagons that served as a darkroom and a developing laboratory.



The invention of the *dry-plate process* overcame the inconvenience of the collodion method. In 1871, Richard L. Maddox, a British physician, used an emulsion of gelatin to coat photographic plates. Unlike collodion, gelatin dried on a plate without harming the silver salts. By using dry plates, photographers did not have to process a picture immediately.

The use of gelatin also eliminated the necessity of keeping a camera motionless on a tripod during exposure. By the late 1870's, improvements in the gelatin emulsion had reduced exposure time to $\frac{1}{25}$ of a second or even less. Photographers could now take pictures while holding the camera in their hands.

In addition to giving photographers greater mobility and freedom, the introduction of the gelatin emulsion revolutionized the design of cameras. Earlier types of printing paper could only be contact printed, and, therefore, negatives had to be as large as the intended print. But photos on paper coated with gelatin could be made by projection printing. Photographers could enlarge such pictures during the printing process, and so the size of negatives could be reduced. Smaller negatives meant smaller cameras.

In 1888, George Eastman, an American dry-plate manufacturer, introduced the Kodak box camera. The Kodak was the first camera designed specifically for mass production and amateur use. It was lightweight, inexpensive, and easy to operate.

The Kodak system also eliminated the need for pho-

George Eastman House, Rochester,

The Kodak camera, invented in 1888 by the U.S. manufactur George Eastman, made picture taking easy. This photo of him was taken with a Kodak identical with the one he is holding.

tographers to process their own pictures. The Kodak used a roll of gelatin-coated film that could record 100 round photographs. After a roll had been used, a pers sent the camera with the film inside to one of Eastman' processing plants. The plant developed the film, made prints, and then returned the camera loaded with a ne roll of film. The Kodak slogan declared: "You Press the Button, We Do the Rest."

Artistic advances. During the 1850's and 1860's, man people began to experiment with the artistic possibilities of photography. One of the first to use a camera cr atively was Gaspard Félix Tournachon, a French photog rapher who called himself Nadar. Nadar added a new element to portrait photography by emphasizing the pose and gestures characteristic of his subjects. However, his most famous achievement was the first aerial photograph, a view of Paris taken from a balloon.

Another pioneer in portrait photography was the Bri ish photographer Julia M. Cameron. She emphasized e pressiveness over technical quality, and so many of her pictures were blurred or out of focus. But Cameron ca tured the personalities of her subjects, who included such famous persons as Sir John Herschel and the British naturalist Charles Darwin.

Landscapes and architecture were also popular subjects for early art photographers. During the 1850's and 1860's, a number of governments commissioned photographers to make visual records of important buildings and natural features in various countries. Photographs were taken of historical sites in Europe and the Middle East, the scenery of the American West, and many other major landmarks. Some of these pictures were remarkable not only for their technical excellence but also for the effort involved in taking them. In 1861, for example, two French photographers named August

ɿd Louis Bisson withstood intense cold and avalanches
ι take pictures from the top of Mont Blanc in France.
e brothers needed so much equipment that they took
porters up the mountain with them.

Some of the most dramatic photographs of the mid-
00's are battlefield scenes. The earliest surviving pic-
es of this type were taken by Roger Fenton, a British
ırnalist covering the Crimean War (1853-1856). The
otos of the American Civil War (1861-1865) made by
athew Brady and his assistants rank among the finest
r pictures of all time.

During the late 1800's, some photographers used
eir pictures to dramatize issues, rather than simply
cord events or create artistic effects. One such pho-
grapher was William H. Jackson, an American, who
ecialized in photographing the Far West. Jackson's
otographs of the Yellowstone area helped persuade
ngress to establish the world's first national park
ere.

Two other American photographers, Jacob A. Riis and
wis W. Hine, took pictures that exposed social evils. In
88, Riis's photographs of the slums of New York City
ocked the public and helped bring about the abolition
one of the city's worst districts (see **Riis, Jacob A.**).
ne, who was a sociologist, documented the miserable
rking conditions of the poor. His pictures of children
rking in coal mines and dimly lighted factories
lped bring about the passage of child-labor laws. See
ild labor.**

The photographic revolution. By the late 1800's, the
velopment of photography was moving in two direc-
ns. The appearance of the Kodak camera and other in-
pensive box cameras had led to a tremendous rise in
e number of amateur photographers. Previously, pho-
graphy had been limited to people who knew how to
e complicated photographic equipment and could af-
d to buy this equipment. Now, almost anyone could
e a picture.

On the other hand, some photographers wanted photography to be considered a creative art in the tradition of drawing and painting. Many of these *pictorial photographers* tried to make their prints look like paintings. They used special printing techniques and paper to give their photographs a texture similar to that of painted canvases. Some photographers even colored the images with paint. In 1902, Alfred Stieglitz, Edward Steichen, and a number of other American photographers formed a group to promote photography as an independent art form. This group, which was called the Photo-Secession, organized photographic exhibitions in the United States and loaned collections of photos to exhibitors in many other countries.

The idea that photographers should imitate painters was soon challenged. After about 1910, many photographers believed that unretouched photographs had a beauty and elegance unmatched by other works of art. Their ideal of "pure" photography influenced such later photographers as Edward Weston and Paul Strand of the United States.

During the 1920's and early 1930's, photography underwent dramatic changes as the result of two major developments. First, photographic equipment was revolutionized by the miniature 35-millimeter camera and artificial lighting. The Leica camera, introduced in 1924 in Germany, was small enough to fit in a pocket, but it produced clear, detailed photographs. Many photographers used the Leica to take *candid pictures,* in which people did not know they were being photographed. The electric flashbulb, introduced in 1929, and electronic flash, invented in 1931, greatly expanded the range of photographic subjects.

The second major development involved experimentation with new ways of composing pictures and viewing subjects. László Moholy-Nagy, a Hungarian, and Man Ray, an American, produced photographs without using a camera. They placed objects on a piece of printing paper and exposed the paper with a flashlight. Other photographers created abstract compositions with X-ray

The Library of Congress, Washington, D.C.

News photography was born during the mid-1800's with the work of Mathew Brady of the United States and other photographers. Brady's pictures of the American Civil War captured both the horror of the battlefield and the humanity of the soldiers. Brady processed his photos by the *collodion method,* which required an enormous amount of equipment. His photographic van can be seen at the right of this picture.

photographs and multiple exposures. The French photographer Henri Cartier-Bresson was one of the first to utilize the creative possibilities of the miniature camera. He tried to capture people's gestures and feelings at "decisive moments" of their lives.

A technique called *documentary photography* developed in the 1930's. During the Great Depression, the Department of Agriculture hired photographers to survey conditions in rural areas of the United States. The outstanding photographers involved in this project included Walker Evans and Dorothea Lange. Their pictures portray the courage and suffering of poverty-stricken farm families. At the same time, the appearance of illustrated news magazines in Europe and the United States created a demand for news photographs. Such photojournalists as Margaret Bourke-White and Robert Capa, both of the United States, vividly recorded some of the most important people and dramatic events of the period.

Other photographers of the 1930's and 1940's concentrated on ordinary subjects or natural scenery. Many pictures taken by Edward Weston and Paul Strand emphasize the textures and geometric shapes of everyday objects. Weston and Strand helped develop the technique of *straight photography,* which features sharply focused, detailed images. Another American photographer, Ansel Adams, specialized in landscapes, especially the mountains and deserts of the West.

During the 1950's and 1960's, photographic styles became increasingly varied, particularly in the United States. The "street photography" of such photographers as Robert Frank and Garry Winogrand followed the tradition of documentary realism. Other photographers experimented with various printing techniques to achieve unusual effects. For example, Robert Heinecken produced some of the most imaginative photographs by making contact prints directly from the illustrated pages of magazines. Other photographers, including Minor White and Aaron Siskind, tried to convey a highly personal, almost spiritual view of the world in their work.

Migrant Girl (1936); The Library of Congress, Washington, D.C.

Documentary photographs may persuade as well as inform. The sensitive portraits of migrant farmworkers by U.S. photographer Dorothea Lange aroused public concern over their plight.

The artistic possibilities of color photography were not fully explored until the 1970's. Color film had been popular among amateur photographers since it was first commercially produced in 1935. However, most professional photographers continued to work almost entirely with black-and-white film. The American photographers Ernst Haas and Marie Cosindas were among the first professionals to concentrate on color photography. Haas's work includes both realistic landscapes and abstract compositions. Cosindas, who chiefly uses instant color film, specializes in still lifes and portraits.

Photography today is firmly established as both an art form and an essential tool in communication and research. Nearly all major art museums hold exhibitions of photographs, and a number of museums specialize in photographic art. A picture by a well-known photographer, such as Paul Strand, may cost as much as a fine painting. At the same time, the practical value of photography has steadily risen in many fields, ranging from advertising to zoology.

Professional photography includes a greater variety of styles and themes than ever before. But much of the work can be broadly classified as either *realistic* or *fanciful.* Among the outstanding realistic photographers are Donald McCullin of Britain and Lee Friedlander of the United States. Many of their photographs vividly document the "social landscape" of their countries. Another realistic photographer is Harry Callahan of the United States, whose work includes detailed, sharply focused pictures that follow the principles of straight photography.

Fanciful photographers may distort the appearance of objects in their pictures to create an illusion or convey a mood. The American photographer Jerry Uelsmann produces dreamlike images by combining several negatives into a single print. Another American photographer, Eileen Cowin, poses herself and her family in settings that suggest images from television soap operas.

Amateur photographers use a wide variety of equipment and techniques. Cameras range from simple fixed-focus models to adjustable ones that have interchangeable lenses and many built-in features. Home processing of both black-and-white and color film has been simplified by easy-to-use equipment and fast-acting chemicals. Amateurs also shoot color home movies with available light, and they make videotape movies that can be shown on a television set.

One of the greatest technical advances in both amateur and professional photography has been the instant processing of film. Ever since the instant camera was introduced in 1947, manufacturers have steadily improved the efficiency and ease of instant processing. The original model was bulky and expensive. But some of today's instant cameras are about the size of a paperback book and cost no more than a good standard camera. Many studio cameras can be adapted for instant photography by means of special attachments.

Careers

hotography offers a wide variety of challenging ca- r opportunities. A person interested in a career in otography should have a general academic back- und and technical knowledge of photography. Many colleges and universities offer courses in pho- raphy, and some have programs that lead to ad- ced degrees in the subject. A number of art schools l technical schools also offer instruction and practical ning in photography. Information about careers in otography can be obtained from Professional Photog- hers of America, Inc., in Des Plaines, Illinois.

Commercial photography. Most commercial pho- raphers take pictures for advertisements or for illus- ions that appear in books, magazines, and other pub- tions. These photographers work with subjects as ied as food, farm equipment, and high-fashion cloth- , and they may be assigned to take photographs at a iety of locations. Commercial photographers must be lled and imaginative in a wide range of photographic hniques.

Portraiture. A portrait photographer takes pictures eople and of special events in the lives of these indi- uals. Some photographers in this field specialize in e type of portraiture, such as children, families, or ddings. Portrait photographers must know how to se their subjects and how to create pleasing effects.

Photojournalism. Most photojournalists take pic- es for newspapers or newsmagazines. They must be lled in seeking out and recording dramatic action in h fields as politics and sports. A photojournalist must o take pictures rapidly and process them quickly.

Scientific photography includes an increasing num- r of specialized areas. Major fields of scientific pho- raphy include *medical photography* and *engineering otography.* Medical photographers provide informa- n used by physicians to diagnose and treat illnesses. ese photographers may work with such medical uipment as microscopes, X-ray machines, and in- red scanning systems. Engineering photographers p engineers improve the design of equipment and uctural materials. These photographers sometimes e special cameras to "stop" the action of machines and make visible the flaws in metal, plastic, and other ma- ials.

Other fields in photography include research, manu- turing, and film processing as well as business man- ement and sales. Careers are also open to people o can teach photography or write about it. In addi- n, a growing number of museums employ people o are experts in the history of photography.

Photolithography. See Photoengraving and photolithography.

Photomultiplier tube is an extremely sensitive electric eye vacuum tube. Most of these tubes are more sensitive to light than is the human eye. Photomultipliers are used to measure very weak light. For example, physicists use them in scintillation counters to measure the light given off by cosmic rays, nuclear particles, gamma rays, or X rays.

A photomultiplier has a *photocathode,* which gives off electrons when light strikes it. These electrons then strike the first of a series of plates called *dynodes.* As the electrons bounce from plate to plate, they knock an ever-increasing number of electrons from each plate. Several million electrons may leave the tube for every electron given off by the photocathode. The tube thus multiplies the effect of the light that strikes it and enables the brightness of the light to be measured with extreme accuracy. Paul L. Gerace

Photon, *FOH tahn,* is the elementary particle that makes up light and all other forms of electromagnetic radiation. Like all particles, photons have properties of waves, including frequency and wavelength. But photons have no mass and no electric charge. The speed at which photons travel in a vacuum is the speed of light. The exchange of photons between electrically charged particles transmits the electromagnetic force, one of the four fundamental forces.

In 1900, the German physicist Max Planck showed that the energy of a photon (then called a *radiation quantum)* is proportional to the frequency of its light. The German-born physicist Albert Einstein carried Planck's discovery further. In 1905, Einstein used the idea of photons to explain the ability of light to knock electrons out of atoms—a phenomenon known as the *photoelectric effect.* His predictions about photons, which were later confirmed by experiment, contributed much to the development of the quantum theory. Joel R. Primack

See also **Light** (Photons); **Quantum mechanics; Radiation.**

Photoperiodism, *FOH toh PIHR ee uh dihz uhm,* is the ability of plants and animals to detect the relative length of daily light and darkness in their environment. Seasonal changes in the length of the day affect such activities as bird migration and the reproductive behavior of plants and animals.

There are three main types of photoperiodic responses. *Short-day responses* occur when the period of light each day is shorter than a certain length of time. For example, in the fall, many birds migrate south in response to shortening days. *Long-day responses* occur when the period of light each day is longer than a certain length of time. In the spring, many plants flower in response to lengthening days. *Day-neutral responses* occur equally well during both long and short days. For example, some plants flower when they reach a certain size, regardless of the length of day. Gerald F. Deitzer

Photosynthesis, *FOH tuh SIHN thuh sihs* or *FOH toh SIHN thuh sihs,* is a food-making process that occurs in green plants. Photosynthesis is the chief function of leaves. The word *photosynthesis* means *putting together with light.*

Green plants use energy from light to combine carbon dioxide and water to make food. All our food comes from this important energy-converting activity of green plants. Light energy is converted to chemical energy and is stored in the food that is made by green plants. Animals eat the plants, and we eat animal products as well as plants.

The light used in photosynthesis is absorbed by a green pigment called *chlorophyll.* Each food-making cell in a plant leaf contains chlorophyll in small bodies called *chloroplasts.* In chloroplasts, light energy causes water drawn from the soil to split into molecules of hydrogen and oxygen. In a series of complicated steps, the hydrogen combines with carbon dioxide from the air, forming a simple sugar. Oxygen from the water molecules is given off in the process. From sugar—together with nitrogen, sulfur, and phosphorus from the soil—green plants can make starch, fat, protein, vitamins, and other complex compounds essential for life. Photosynthesis provides the chemical energy needed to produce these compounds.

Certain bacteria and algae can also capture light energy and use it to make food. For example, *photosynthetic bacteria* contain chlorophyll in tiny bodies called *chromatophores.* In chromatophores, compounds other than water are combined with carbon dioxide to form sugar. No oxygen is released.

Green plants convert carbon dioxide and water into food and oxygen. Plants and animals, in turn, "burn" the food by combining it with oxygen to release energy for growth and other activities of life. This process, which is called *respiration,* is the reverse of photosynthesis. Oxygen is used up and carbon dioxide and water are given off. Plants then use the carbon dioxide and water to produce more food and oxygen. The cycle of photosynthesis and respiration maintains the earth's natural balance of carbon dioxide and oxygen. David H. Wagner

Phototypesetting. See Photocomposition.

Phrenology, *frih NAHL uh jee,* is the practice of analyzing a person's character by examining the shape of the skull. Phrenology was developed during the early 1800's by two German physicians, Franz Joseph Gall and Johann Kaspar Spurzheim. Phrenology was once considered a science. Most people now regard it as a *pseudoscience* (false science).

Phrenology was based on the belief that different areas of the brain control different aspects of behavior. Gall and Spurzheim believed the skull could be mapped to show the locations of these areas, which they called *organs.* Some organs governed personality traits, and others controlled mental abilities.

According to phrenologists, a person's outstanding traits could be identified by bumps or bulges on the head. These swellings were caused by the enlargement of the organs related to each powerful trait. For example, a musician would have a well-developed *organ of tune* and a mathematician would possess a large *organ*

number. Phrenologists also believed that certain
mps identified people as poets or thieves.
Phrenology gained great popularity in Western Eu-
e and North America during the early and mid-
00's. Notable people who believed in phrenology in-
ded Queen Victoria of Britain and the American
ets Walt Whitman and Edgar Allan Poe.
Today, scientists know that a personality trait is not lo-
ized in any one area of the brain. Different parts of the
in have different functions, but the parts interact in a
re complex way than phrenologists realized. Never-
less, phrenology did help pave the way for the scien-
c study of personality, and thus for modern psycholo-
Christopher McIntosh

rygia, *FRIHJ ee uh,* was an ancient country between
Mediterranean Sea and the Black Sea, in what is
w central Turkey. The Phrygians were an Indo-Euro-
an people who came from southeastern Europe after
00 B.C. and settled in lands once ruled by the Hittites.
gends tell that the early Phrygian kings included
rdius and Midas, whose great rock tombs may still
seen in the mountains. See **Gordian knot; Midas.**
Cimmerians—invaders from around the Caucasus
ountains—conquered Phrygia about 700 B.C. Phrygian
mmunities still existed to about 550 B.C. The Phrygians
er came under Persian, Greek, and Roman rule. They
re known for their art and ceramics, and skill in
nb-building. They contributed many Oriental ideas to
early Greeks, especially in music. The Romans
opted the Phrygian worship of the goddess Cybele,
o was the Great Mother of the Gods. Ronald P. Legon

hyfe, *fyf,* **Duncan** (1768-1854), a well-known Ameri-
n cabinetmaker and furniture designer, popularized
Federal style of American furniture. He adopted that
le from the English neoclassical style of the mid-
00's.
Phyfe based his designs on English pattern books of
day, especially those of Thomas Sheraton and
omas Hope. Phyfe became known for his chairs,
nches, and other seating furniture. He manufactured
airs with backs shaped like scrolls. The chairs had a
lat—a piece of wood that formed the center of the
ck. A typical splat was shaped like a harp or a lyre.
Phyfe was born in Loch Fannich near Inverness, Scot-
nd. He emigrated to America in 1782. By 1792, Phyfe
d established a shop in New York City. He eventually
erated one of the largest furniture factories in the
ited States. Nancy E. Richards
See also **Furniture** (Early American furniture).

hylloxera, *FIHL ahk SIHR uh,* is any one of a group of
all insects that resemble *aphids* (plant lice). They feed
trees and shrubs.
One of the most important kinds of phylloxerae is the
ape phylloxera. This insect sucks the sap from the
ves and roots of grapevines, causing *galls* (swellings).
e damage to the root stunts and often kills the vine.
e grape phylloxera is native to the eastern United
ates. The vines in this region resist them, but these in-
cts do much damage in the western United States and
Europe. They are controlled by grafting the vines to
otstock from the eastern United States and by periodi-
lly flooding or fumigating the soil.
The life cycle of the grape phylloxera lasts two years.
rtilized eggs are laid under the bark of the vine in the
fall. In the spring, these eggs hatch into wingless young that move to the leaves to feed. They lay unfertilized eggs, which soon hatch. Several of these generations are produced during the summer. In the fall, the young insects move to the roots and hibernate there during the winter. During the next spring and summer they feed on the roots and produce young from unfertilized eggs. As fall approaches, winged insects are produced that lay eggs in other vines. After these eggs hatch, the insects mate, the females lay fertilized eggs, and the cycle repeats.
John R. Meyer

Grape phylloxerae, small aphidlike insects, attack a root of a grapevine.

Scientific classification. Phylloxerae are in the family Phylloxeridae. The scientific name for the grape phylloxera is *Daktulosphaira vitifoliae.*

Phylum. See Classification, Scientific.

Physical change is a change of matter from one form to another without the production of any new substances. All chemical compounds present before the physical change are present afterward. Because no change in chemical structure occurs, there is no change in solubility, taste, odor, or ability to react chemically. For example, when wood is turned into sawdust, the change is physical. But if the wood were burned, new substances, ash and gas, would result, so the change would be chemical. Another example of a physical change is the melting of ice to water. Lucille B. Garmon

Physical chemistry is the study of the general rules and principles that govern the chemical properties of matter. Physical chemistry is primarily concerned with (1) whether a particular chemical reaction will occur and (2) how fast and by what mechanism the reaction will proceed. The study deals with such problems as how and why atoms join together in molecules; how atoms and molecules form gases, liquids, and solids; how atoms and molecules absorb and emit energy; and how electricity relates to chemistry. Raymond P. Borkowski

See also **Chemistry** (Development of physical chemistry).

Physical disability. See Disabled.

Physical education is a part of the school instructional program that focuses on development through participation in various forms of bodily activity. Physical education programs encourage students to develop skills and enjoyment of exercise that will help them remain active throughout their lives. Courses in physical education are offered in all grades, from preschool through college. Students participate in a wide variety of activities, including basic movement, dance, fitness, games, recreational activities, and sports.

Teachers help students learn to enjoy physical activity by creating a noncompetitive environment that encourages individual development. Within such a supportive environment, students improve their fitness and basic motor skills, such as running and jumping. They also take part in a variety of games and sports. As students

participate, they develop skills and strategies and increase their enjoyment of exercise.

Elementary school programs

Physical education programs in preschool through grade 2 focus on basic motor skills. Educators call this approach *movement education.* Teachers also encourage individual development and help students extend their basic skills with the *problem-solving method.* In this method, students work out their own solutions to a problem, such as how to balance on a narrow beam.

Programs in grades 1 and 2 also include elementary games, which stress participation by all students and cooperation rather than competition. Through participation in these games, children learn how to behave in play situations and how to get along with others in a group. Dance activities and exercises done to music are also included in these programs.

Programs in grades 3 and 4 help youngsters begin to develop the skills needed for many popular activities and sports. Children play simplified forms of such games as basketball, soccer, and volleyball. They also take part in gymnastics and track-and-field events.

In grades 5 and 6, students learn more advanced skills and strategies in team sports, such as softball and soccer. They also begin to learn individual sports, such as archery and golf. If facilities are available, they begin swimming and other water activities.

In grades 7 and 8, students learn more about fitness and strength development. Instructors may also introduce cooperative adventure games that require group problem solving. These games develop decision making, leadership, and cooperation skills.

Secondary school programs

Physical education programs in junior and senior high school continue instruction in many activities offered i elementary school programs. The teachers provide more advanced instruction, however, and the activities are more organized and demanding. The programs als add new sports, such as field hockey and badminton.

High school programs consist chiefly of sports that are popular lifetime recreational activities. Examples in clude bowling, bicycling, handball, skating, and tennis. Instructors regularly evaluate student performance anc knowledge in fitness and sports.

Some high schools allow juniors and seniors to choose part of their physical education program from number of nonrequired activities called *electives.* Students also may participate for credit in independent study projects or in a sports program outside school.

A growing number of high schools offer special courses in physical fitness. These courses combine classroom studies, laboratory tests to measure fitness, and individually designed exercise programs.

Many junior and senior high schools offer *interscholastic* sports, in which schools compete against each other, as an extension of their physical education programs. Popular interscholastic sports include baske ball, football, volleyball, soccer, gymnastics, and tennis Many schools also offer *intramural* programs, which in volve students from the same school. Intramural programs enable students to participate in sports tournaments and recreational activities after school.

University and college programs

Most colleges and universities offer physical education programs. Students at some schools must take one or two years of physical education. At other schools, these courses are optional. College-level students may continue a sport they played in high school or learn a new one. Large universities offer many activities not

© Ellis Herwig from Marilyn Gartm

Elementary-school children do arm exercises in this physical education class to develop and understand basic movements.

ilable at smaller schools, such as sailing and skiing.
Many colleges and universities offer bachelor's de-
es in physical education. These degrees require the
dy of such subjects as anatomy, sports techniques,
teaching methods. Some institutions also offer mas-
or doctor's degrees in physical education.

History of physical education

arly history. Many experts trace the origins of mod-
physical education to the ancient Greeks, who had
eloped organized physical education programs by
700's B.C. Greek boys attended educational facilities
ed *gymnasiums,* where they received physical and
tary training. Some gymnasiums also provided in-
iction in philosophy and other subjects. At the gym-
iums, boys took part in jumping, running, and
stling. They also practiced throwing a platter-shaped
ect called the *discus* and a spear called the *javelin.*
ancient Rome, physical education served chiefly as
paration for battle. Soldiers practiced swimming,
ning, jumping, and throwing to increase their fitness.
he Middle Ages, which began in the A.D. 400's and
ed until about the 1500's, were marked by a decline
ll types of formal schooling, including physical edu-
on. People of this time considered many sports and
er physical activities sinful.
uring the Renaissance, a period lasting from about
0 to about 1600, many Greek and Roman educational
as were revived. Students again took part in boxing,
mming, and other body-building activities.

uring the 1800's, physical education programs
e introduced into schools in Germany, Sweden, and
United Kingdom. German and Swedish programs
ured gymnastics and exercise routines. British
ools emphasized team sports. Physical education
ead to the United States during the mid-1800's under
h names as *physical culture* and *physical training.*
U.S. programs borrowed activities and teaching
thods from the European programs.
ntercollegiate competition in baseball, football, and
er sports began during the late 1800's and early
0's. These sports grew rapidly in popularity and led
ncreased interest in physical education.

uring the 1900's, physical education began to in-
de groups that formerly were denied chances to par-
pate. For example, few female students took physical
ication until the late 1800's, and even then most class-
vere segregated by sex. By the late 1900's, most phys-
education classes included both sexes. Males and
ales competed separately in only a few sports, and
ny more sports became available to females. In addi-
, federal laws passed in 1969 and 1970 required
ools receiving federal funds to provide physical edu-
on programs for students with disabilities at all edu-
onal levels.
uring the 1990's, physical education gained new em-
sis because of scientific studies showing that exer-
improves health. In 1996, the surgeon general of the
ted States released a report on physical activity and
lth. This report said that regular, moderate exercise
significantly reduce the risk of dying from heart dis-
e, high blood pressure, colon cancer, and diabetes.
report noted, however, that almost half of American
ths from 12 to 21 years old are not regularly active.
Several other studies in the 1990's showed that children had less strength and endurance, and more weight problems than earlier generations of children had. The U.S. Centers for Disease Control and Prevention began a major effort to help states, national organizations, and professional groups promote physical activity.

Physical education today stresses helping children develop good exercise habits and a healthy lifestyle, rather than win competitions. As a result, schools put new emphasis on preparing students for lifelong fitness based on regular physical activity.

Careers in physical education

Most careers in physical education involve teaching. Physical education teachers in public schools must have a bachelor's degree and a *teaching certificate,* a license to teach awarded by each state. Many physical education teachers also coach interscholastic sports.

Physical education instructors in colleges and universities teach classes and direct intramural sports. They also give teacher-training classes for future physical education teachers. In addition, some physical education teachers coach intercollegiate sports. Many instructors at the college level have a master's or doctor's degree.

Other individuals with degrees in physical education direct recreation programs at day-care centers, parks, or prisons. Some careers in physical education—for example, athletic trainer or sports administrator—require both training in physical education and additional study in a related field. Daryl Siedentop

Physical fitness

Physical fitness is the ability to meet the physical demands of daily life and to resist diseases associated with inactivity. Physical fitness enables people to perform well in sports and other activities, and to look and feel their best.

Physical fitness can be classified into two main kinds: (1) performance-related and (2) health-related. People face different physical demands in the course of their occupations and leisure time. Therefore, the necessary type of conditioning, which may be called performance-related physical fitness, varies from one individual to another. For example, a stockbroker who runs marathon races for recreation requires a high capacity of the heart and lungs to deliver oxygen to leg muscles. On the other hand, a factory worker who lifts heavy crates but reads for relaxation primarily requires great leg and upper body strength to meet daily physical challenges.

The requirements for health-related fitness are similar for all people. Everyone must maintain certain aspects of health-related fitness to feel good and to resist disease.

Performance-related fitness

Performance-related physical fitness includes such qualities as muscular strength, aerobic power, anaerobic power, anaerobic capacity, and flexibility.

Muscular strength is the ability to produce force in a single effort. This type of strength is vital to such athletes as discus and javelin throwers, football linemen, shot-putters, and powerlifters.

Some ways to achieve physical fitness

Women in a physical fitness class exercise to keep their muscles strong and limber, *left.* Runners race in the park to build their strength and endurance, *center.* Many people keep fit by maintaining an exercise program that includes weightlifting on specialized machines, *right.*

© Annie Griffiths, West Light

© Michael Kevin Daly, The Stock Market

Ellis Herwig, Stock, Bo

Aerobic power is the highest rate at which a person's body can produce energy in the muscles through the use of oxygen. Aerobic power depends on good lung function to supply oxygen to the blood, a strong heart to pump blood to the muscles, and muscles that are efficient in using the oxygen sent to them. Great aerobic power is common among endurance athletes, including cyclists, distance runners, rowers, and distance swimmers. These athletes may have twice the aerobic power of untrained people.

Anaerobic power is the ability to produce great force quickly, a combination of speed and strength. The term *anaerobic* means *without oxygen.* Highly anaerobic activities use up energy so fast that they can be sustained for only 30 seconds or less. Anaerobic power is needed in such events as the high jump, long jump, 50- to 100-meter sprints in track, rebounding in basketball, and weightlifting.

Anaerobic capacity is the ability to sustain great force for up to 30 seconds. It is important in 200- and 300-meter sprints in track; 25- and 50-meter swims; and any sport involving brief bursts of maximum effort.

Flexibility is the range of motion of body joints. Great flexibility is needed in such activities as dance, gymnastics, high jumping, hurdling, long jumping, and wrestling. A high degree of flexibility may also help prevent certain sports injuries.

Health-related fitness

Health-related fitness includes such qualities as aerobic power, flexibility of the spine, abdominal strength, body fat, cholesterol levels, and glucose tolerance.

Aerobic power enables a person to comfortably perform such activities as cycling, racquetball, rowing, running, stair climbing, swimming, vigorous walking, or yard work. Participation in aerobic activities on a regular basis can reduce the risk of *coronary artery disease,* tl most common form of heart disease. Along with diet control, these activities can also help prevent *obesity* (being too fat) and *osteoporosis* (loss of bone tissue).

Flexibility of the spine involves the range of motic of the joints of the spinal column. It is important for re ducing the risk of low back pain. When in a sitting pos tion with both legs extended, a person should be able reach within about 4 inches (10 centimeters) of his or her toes.

Abdominal strength also helps reduce back pain. The abdominal muscles should be strong enough for person to do about 20 bent-knee sit-ups easily.

Body fat. The percentage of body tissue that consis of fat and the distribution of that fat are important factors in a wide variety of diseases. The percentages of body fat for young adult men should fall between abo 5 and 20 percent and between about 12 and 30 percer for young adult women. Levels over 20 percent in mer and 30 percent in women contribute to health risks, in cluding arthritis, diabetes, gall-bladder disease, heart disease, and high blood pressure. People whose fat is mainly in the abdominal area have a greater risk of he disease than people whose fat accumulates chiefly in the hips and thighs. Exercise helps prevent excess fat.

Cholesterol levels. Cholesterol is a waxy, fatty sub stance found in animal tissues and the food that come from them. High levels of cholesterol in the blood increase a person's risk of coronary artery disease. Mor important than the total amount of cholesterol, howev are the relative amounts of *lipoproteins,* large molecules that carry cholesterol through the blood. There are two main types of cholesterol-carrying lipoproteir (1) *low-density lipoproteins (LDL's)* and (2) *high-density lipoproteins (HDL's).* Cholesterol in the blood can be identified as either LDL-cholesterol or HDL-cholestero

pending on which lipoprotein carries it. High levels of L-cholesterol increase the risk of coronary artery dis-e, but HDL-cholesterol seems to reduce that risk. ple who engage in regular aerobic exercise lower ir levels of harmful LDL's and increase their beneficial L's. See **Cholesterol**.

Glucose tolerance is how the body responds to a ding of a sugar called *glucose*. Healthy people can sume foods containing glucose without developing essive amounts of glucose in their blood. Elevated els of glucose in the blood indicate *diabetes mellitus,* rious disease in which the body cannot use glucose mally. Regular aerobic exercise may improve glu-e tolerance and improve the function of *insulin,* a mone that regulates blood glucose.

Developing physical fitness

To achieve and maintain physical fitness, people uld eat a balanced diet and exercise regularly. A bal-ed diet includes all the nutrients the body needs to ain healthy. Nutritionists have developed various delines to encourage good nutrition. See **Nutrition** trition guidelines).

Physical education programs in schools help children elop good fitness habits. In the United States, the sident's Council on Physical Fitness and Sports rec-mends that all elementary and high schools provide eriod of at least 20 to 30 minutes of vigorous exercise ly. An effective school program also offers team rts, courses in health care, and performance tests to asure students' progress in physical fitness.

Health experts recommend at least 20 minutes of vig-us aerobic exercise three to five times per week for lts to develop and maintain aerobic power and to p control body fat, cholesterol, and glucose toler-e. But a less vigorous exercise program can also e important health benefits, especially for reducing risk of heart disease. Such a program should include minutes or more of moderate exercise—such as walk-, easy bicycling, or gardening—at least five days a ek. Men over age 40, women over 50, and anyone h risk factors or symptoms of heart or lung disease uld check with their physicians before starting a vig-us exercise program. David R. Lamb

ysical science. See Science (The physical sci-es).

ysical therapy is the use of physical means, such ight, heat, cold, and exercise, to treat disease or in-. Physical therapy is used to help prevent, relieve, or rect conditions that interfere with a person's physical lity to function normally. It is administered by health e professionals called *physical therapists.*

Uses of physical therapy. Physical therapy is helpful in treating many diseases and disabilities. It is often used in treating heart and lung diseases and various types of paralysis and muscle weaknesses, such as strokes and multiple sclerosis. It is also important in amputations, fractures and other injuries, and other orthopedic conditions. With the aid of physical therapy, a disabled person may lead a constructive and creative life.

Aids in physical therapy. Many kinds of equipment, exercises, and self-help devices are used to help people with disabilities. Radiant heat lamps, electric heating pads, diathermy, hydrotherapy, and paraffin baths are used to apply heat. Heat relieves pain, improves circulation, and relaxes muscles. Cold, when used soon after injury, lessens pain, hemorrhage, and swelling. Ultraviolet radiation attacks germs and helps heal certain skin disorders. Ultrasound treats inflammatory conditions of joints, muscles, and nerves, and painful amputation stumps.

Exercise helps to maintain and improve body function and posture. It increases muscle tone, strength, and endurance. Some exercises can be performed by the patient alone. For others, the patient might need the help of the therapist. Often mechanical devices, such as parallel bars, stationary bicycles, pulleys, weights, and dumbbells, are used. Self-help devices, such as splints, braces, crutches, and wheelchairs, help disabled people perform daily activities. Physical therapists train people to use these devices and to develop confidence in accomplishing daily tasks.

Careers in physical therapy. Men and women who want to be physical therapists can choose one of three kinds of educational programs. One program leads to a bachelor's degree in physical therapy. The other two programs are for people who already have a bachelor's degree in some other field. One of these programs involves 12 to 18 months of study leading to a certificate in physical therapy. The other program leads to an entry-level master's degree in physical therapy. Physical therapy programs include courses in anatomy, clinical medicine, physiology, psychology, therapeutic exercise, and the use of physical and electrical equipment.

Physical therapists work in such places as clinics, hospitals, schools for disabled individuals, private offices, academic institutions, home health agencies, and nursing homes. In the United States, physical therapists must be licensed before they may practice.

The American Physical Therapy Association is a national organization for physical therapists. It publishes the professional journal, *Physical Therapy,* and other informational material, such as *Careers in Physical Therapy.* Headquarters are in Alexandria, Virginia.

Research in physics explores the structure and behavior of matter and attempts to answer questions about energy. The work of physicists includes developing theories, performing experiments, and improving manufacturing processes and products.

Physics

Physics is the science devoted to the study of matter and energy. Physicists try to understand what matter is and why it behaves the way it does. They seek to learn how energy is produced, how it travels from place to place, and how it can be controlled. Physicists are also interested in how matter and energy are related to each other and how they affect each other over time and through space.

The word *physics* comes from a Greek word meaning *natural things*. Knowledge obtained from the study of physics is important in other sciences, including astronomy, biology, chemistry, and geology. There is also a close connection between physics and practical developments in engineering, medicine, and technology. For example, engineers design automobiles and airplanes according to certain principles of physics. Laws and theories of physics have enabled engineers and scientists to put satellites into orbit and to receive information from space probes that travel to distant regions of the solar system. Research in physics has led to the use o radioactive materials in the study, diagnosis, and trea ment of certain diseases. In addition, theories and pri ciples of physics explain the operation of many mode home conveniences, from vacuum cleaners to video tape recorders.

James Trefil, the contributor of this article, is the Clarence J. Robinson Professor of Physics at George Mason University.

What physicists study

Physicists try to answer basic questions about the world, how it is put together, and how it changes. So physicists, called *experimental physicists,* perform ca fully designed experiments and then compare their r sults to what was predicted to happen. Such predictio come from laws and theories developed by another group of physicists, called *theoretical physicists.* Thes laws and theories are almost always expressed in the language of mathematics, a basic tool of physics.

The subjects studied by physicists consist of two broad categories, *classical physics* and *modern phys* These two categories differ primarily in emphasis. Cl sical physics deals with questions regarding motion energy. It includes five important areas: (1) mechanics heat, (3) sound, (4) electricity and magnetism, and (5) light. Modern physics concentrates on scientific beli

ɔut the basic structure of the material world. Its major ds include (1) atomic, molecular, and electron ysics; (2) nuclear physics; (3) particle physics; (4) solid-e physics; and (5) fluid and plasma physics.

Mechanics is the study of the effects of forces on dies at rest or in motion. For example, it describes v force acts upon an object to produce acceleration. mechanics of bodies that undergo a change in mo-n because of forces acting upon them is called *dy-mics.* The mechanics of bodies at rest or in motion at onstant speed and in a constant direction is called *tics.* One branch of mechanics, known as *fluid me-nics,* deals with the behavior of liquids and gases. nciples of mechanics are used in describing such es of motion as planetary orbits and the paths of oth-moving objects. They are also important to designers bridges and other structures, containers, roads, and ious kinds of vehicles. See **Mechanics; Dynamics; tics.**

Heat. The study of heat is called *thermodynamics.* It olves investigating how heat is produced, how it is nsmitted from one place to another, how it changes tter, and how it is stored. Heat energy can be trans-med into other kinds of energy, and other kinds of ergy can be transformed into heat energy. For exam-, when coal is burned, the chemical energy that ds its molecules is partially transformed into heat. ermodynamics also includes *cryogenics,* the study of terial at very low temperatures. Principles of thermo-namics are essential for understanding all types of t engines, as well as refrigerators and freezers. See **at; Thermodynamics.**

Sound. The study of sound is called *acoustics.* Sound nsists of vibrations that are produced by an object l which travel through a medium, such as air, water, he walls of a building. Understanding sound is im-tant for designing auditoriums, hearing aids, tape orders, phonographs, and speakers. The study of nd also includes *ultrasonics,* which deals with vibra-ns that have frequencies too high for human beings near. See **Acoustics; Sound.**

Electricity and magnetism are so closely related t scientists often refer to the two of them together as *ctromagnetism.* The motion of electric charges can duce magnetic effects, and magnetic forces can produce electrical effects. A combination of these effects produces *electromagnetic radiation,* which includes visible light, radio waves, and X rays. Knowledge of this relationship has led to the development of huge electric generators and many electronic devices. See **Electricity; Electromagnetism; Electronics; Magnetism.**

Light. The study of light is called *optics.* Optics has two major branches, *physical optics* and *geometrical optics.* In physical optics, physicists study the nature of light and the physical processes by which it is *emitted* (given off) from bodies and transmitted from place to place. Geometrical optics is the study of how light travels, and how the direction of travel is affected by different materials. It is important in understanding the lenses and mirrors which are used in telescopes, microscopes, and eyeglasses. See **Light; Optics.**

Atomic, molecular, and electron physics are concerned with understanding the structures of molecules and atoms. In particular, these fields of physics concentrate on the behavior, arrangement, motion, and energy states of the electrons that orbit atomic nuclei. Studies in atomic, molecular, and electron physics have revealed much about the structure of matter. For example, scientists have determined that substances differ from one another in the arrangement of the atoms of their molecules. Because of this difference, the way that each substance absorbs and emits electromagnetic energy is unique. As a result, scientists are able to identify a substance on the basis of its electromagnetic activity alone. This method of identification has important applications in medicine and in certain industrial situations where minute amounts of a material are involved. See **Atom; Electron; Molecule.**

Nuclear physics involves the study of the structure and properties of the atomic nucleus. It focuses on radioactivity, fission, and fusion. *Radioactivity* is the process by which certain nuclei spontaneously give off high-energy particles or rays. Radioactive materials are used to treat cancer and diagnose illnesses, and to trace chemical and physical processes. *Fission* is the process in which an atomic nucleus splits into two nearly equal parts, releasing a huge amount of energy. It provides the energy for atomic bombs and nuclear reactors. *Fusion* is the process in which the nuclei of two atoms join together to form the nucleus of a heavier element. It oc-

jor branches of physics

hanics deals with the behavior of objects and systems in onse to various forces.
Molecular physics examines the structure, properties, and behavior of molecules.
Nuclear physics is concerned with the structure and properties of the atomic nucleus, and with nuclear reactions and their applications.
Optics is the study of the nature and behavior of light.
Particle physics, also called *high-energy physics,* analyzes the behavior and properties of elementary particles.
Plasma physics is concerned with the study of highly *ionized* gases—that is, gases that have been separated into positively and negatively charged particles.
Quantum physics includes various areas of study based on *quantum theory,* which deals with matter and electromagnetic radiation, and the interactions between them.
Solid-state physics, also called *condensed-matter physics,* examines the physical properties of solid materials.
Thermodynamics is the study of heat and other forms of energy, and of the conversion of energy from one form to another.

curs primarily with hydrogen and other light elements. Fusion, which releases more energy than does fission, produces the energy of the sun and other stars. Fusion also powers the hydrogen bomb. See **Nuclear physics.**

Particle physics. Physicists have discovered that the protons, neutrons, and other particles within atomic nuclei are formed of still more elementary particles called *quarks.* Particle physicists conduct research by using devices called *particle accelerators.* These devices can raise subatomic particles to very high speeds. When these particles have reached speeds very close to the speed of light, they are allowed to collide with ordinary matter. Physicists then study the fragments that result from the collisions and measure their energy. In this way, they hope to understand how protons, neutrons, and other subatomic particles behave. See **Particle accelerator.**

Solid-state physics, also called *condensed-matter physics.* Solids may be classified according to how the electrons and nuclei of the different atoms that make them up interact with each other. Physicists who study solids are interested in how the properties of these materials are affected by such factors as temperature and pressure. For example, at extremely low temperatures, some solids lose all electrical resistance, thereby becoming *superconductors.* Research on the electronic structure of solids is especially important in understanding the behavior of *semiconductors,* which serve as the basis of modern electronic devices. See **Semiconductor; Solid-state physics; Superconductivity.**

Fluid and plasma physics. The modern physics of fluids is built on the principles of classical fluid mechanics. Understanding the behavior and movement of fluids is important for the design and construction of automobiles, ships, airplanes, and rockets, as well as for the study of weather. Plasma physics concerns the study of substances called *plasmas.* When enough energy is introduced into a gas, the gas becomes *ionized* (separated into positively and negatively charged particles). The result is a plasma. Plasmas are used in neon lights and fluorescent lamps. Physicists are studying how plasmas might be controlled and used to produce fusion energy to generate electric power. See **Fluid mechanics; Hydraulics; Plasma.**

History

Through the centuries, physics has been closely linked to developments in technology and to advances in mathematics, astronomy, and other sciences. The use of the word *physics* in its current sense was first recorded in the 1700's.

The beginnings of physics date back to prehistoric times. Stonehenge and the other huge rock structures prehistoric people built indicate that they had some knowledge of mechanics. Such knowledge would have been necessary for them to transport these rocks and to place them on top of one another. In addition, there is strong evidence that prehistoric people may have used these rock structures to mark significant moments in the seasonal cycle of the sun and moon.

The first people to leave written records of their discoveries and inventions were the Sumerians, Babylonians, and Egyptians. By around 3000 B.C., the Sumerians had developed a number system, and they used algebraic formulas for following and predicting movement of the stars, sun, moon, and planets. Similar developments occurred in Egypt and Babylonia. The Egyptians also developed practical geometric techniques for use in construction and land surveying.

The Greeks appear to have been the first people to develop general theoretical systems of mathematics ar natural science. Beginning about 600 B.C., they developed a general understanding of the principles of geometry. The Greek mathematician Euclid organized these principles into a unified system about 300 B.C.

The Greeks were keen observers of the physical world. In the 300's B.C., the philosopher Aristotle provi ed proofs, based on physical evidence, of the spherica shape of the earth. In the 200's B.C., the astronomer Eratosthenes calculated the circumference of the earth, and Aristarchus, another astronomer, estimated the re tive distances to the moon and sun. Also during the 200's B.C., the mathematician and inventor Archimedes discovered several basic scientific principles and deve oped ways of calculating areas and volumes.

In the A.D. 100's, Ptolemy, an astronomer in Alexandria, Egypt, developed a model for predicting the posi tions of the sun, moon, stars, and planets. Like Aristotle and other Greek philosophers, Ptolemy viewed the ea as the center of the universe. Ptolemy's system served a guide for predicting the motion of the heavenly bodi for nearly 1,500 years.

The Middle Ages began in about the 400's with the fall of the Roman Empire. At that time, records of Gree scientific discoveries were lost to western Europe. Fro about 400 to 1000, most educated people in Western E rope felt that religion, rather than scientific investigatio should provide the answers to questions about the un verse.

Much of the Greek written tradition in science was preserved during the early Middle Ages by people in the Middle East. These people translated many of the Greek works into Arabic. Arabic scholars wrote commentaries on these texts, made astronomical observations, and performed experiments in optics and mechanics.

Trade between the Arab cultures of the East and the Christian cultures of the West increased during the 1000's. As a result, Greek scientific documents were reintroduced into the West, this time as translations from Arabic to Latin. At first, the science of Aristotle ar other Greeks was rejected by the church. But during tl 1200's, Saint Albertus Magnus, Saint Thomas Aquinas, and other religious scholars successfully reconciled Aristotelian physical science with church principles.

During the 1100's and 1200's, there was also increas ing interest in scientific observation and experiments. For example, various writings, including those of the English scholars Robert Grosseteste and Roger Bacon proposed effective methods for scientific research.

Practical inventions in agriculture and other fields a sparked scientific inquiry in Europe during the Middle Ages. In China and other Asian countries, scientific act ity and invention flourished during this period. Howev er, unlike in the West, science and technology had litt influence on each other.

The Renaissance is the name given to the period i Europe that extended from about the early 1300's to

ut 1600. It was a time of social, economic, political, intellectual excitement that produced many new ap-aches in both the arts and the sciences.

n the 1300's, at Oxford University and the University aris, such scholars as Richard Swineshead and ole Oresme investigated the problem of the descrip- of motion. During the 1400's and 1500's, the famous an painter and inventor Leonardo da Vinci also con-ted studies of motion and hydraulics.

n 1543, the Polish astronomer Nicolaus Copernicus lished a revolutionary astronomical system in which placed the sun—instead of the earth—at the center of universe. Copernicus proposed that the earth was of the planets, all of which orbited the sun. At the e, almost no one accepted his point of view. Many holic and Protestant leaders felt that his system was onflict with their religious beliefs. There were also ous scientific objections to the system. Acceptance he Copernican system required a complete rethink-of the whole basis of physical science. Such a re-king did in fact occur over the next 150 years, pri-ily through the work of such major figures as leo, Johannes Kepler, and Rene Descartes.

eginning in 1609, the Italian astronomer and physi-Galileo built telescopes for observing the heavens. ile none of Galileo's observations with his telescopes ved the Copernican system, they did question tradi-al views. Galileo also perfected the idea of the labo-ry experiment in his study of the motion of falling ies. He showed that a person could gain an under-ding of the way objects fall toward the earth by as-ing that, in the absence of disturbing influences, all objects accelerate at the same constant rate.

the early 1600's, the German astronomer and math-tician Johannes Kepler used the observations of oth-to construct a new and accurate model of the solar em. In the mid-1600's, Rene Descartes, a French philosopher and mathematician, challenged the long-standing assumption that an absence of motion was the natural state of all objects. Instead, he proposed that objects have inertia—that is, they maintain whatever their state of motion unless otherwise disturbed.

The work of Galileo, Kepler, and Descartes reflects a change in attitude that occurred during the Renaissance. People came to believe that natural laws governed the physical world, and it was seen as possible to discover those laws through careful measurements carried out, if possible, under controlled laboratory conditions.

Newton. By the 1600's, a great deal of scientific activity was underway. The climax of this increased activity was the publication, in 1687, of *Philosophiae Naturalis Principia Mathematica* (*Mathematical Principles of Natural Philosophy*) by the brilliant English scientist, Sir Isaac Newton. In this work, Newton showed how both the motions of heavenly bodies and the motions of objects on or near the surface of the earth could be explained by four simple laws. These laws were Newton's three laws of motion and his law of universal gravitation.

Newton's laws of motion summarized and extended the work of Galileo and Descartes. His law of universal gravitation explained both Galileo's law of falling bodies and Kepler's laws of planetary motion. To conduct some of his research and calculations, Newton invented calculus, a new form of mathematics. Mathematical scholar Gottfried Wilhelm Leibniz of Germany independently developed calculus about the same time. See **Calculus**.

In addition to his theoretical discoveries, Newton constructed the first reflecting telescope. Using prisms, he performed ingenious experiments on light that led him to propose that white light was a mixture of all colors. In 1704, he published a particle theory of light. This theory competed with another theory of light that had been proposed by the Dutch physicist Christiaan Huygens in 1678, but not published until 1690. Huygens had

ortant dates in physics

s B.C. Aristotle formed theories in many areas of physics.
s B.C. Archimedes proved the law of the lever and discov- laws for the behavior of liquids.
100's Ptolemy pictured the earth as standing still, with the moon, planets, and stars moving in circles around it.
70 Roger Bacon conducted studies in optics.
Nicolaus Copernicus wrote that the earth and planets e in circles around the sun.
00 Galileo discovered important laws in many fields of ics, especially mechanics.
Sir Isaac Newton published his laws of motion.
Christiaan Huygens published a wave theory of light.
Benjamin Thompson, Count Rumford, stated that the mo- of particles in a substance produced heat.
-1803 Thomas Young revived the wave theory of light.
John Dalton first proposed his atomic theory about the ture of matter.
y 1830's Michael Faraday and Joseph Henry independently uced electricity with magnetism.
James P. Joule found that heat and energy are interchange- at a fixed rate.
James Clerk Maxwell published his electromagnetic theo- light.
Wilhelm C. Roentgen discovered X rays.
Antoine Henri Becquerel discovered natural radioactivity.
Marie Curie and her husband, Pierre, discovered the ra- tive element radium.
Max Planck published his quantum theory.
1905 Albert Einstein published his special theory of relativity.
1911-1913 Ernest Rutherford and Niels Bohr proposed "planetary system" models of the atom.
1915 Einstein announced his general theory of relativity.
1924 Louis de Broglie put forth the wave theory of the electron.
1925-1926 Erwin Schrödinger and Werner Heisenberg separately developed systems for organizing quantum physics.
1930 Paul A. M. Dirac predicted the existence of the *positron,* a positively charged electron.
1932 John D. Cockcroft and Ernest T. S. Walton became the first to break down atomic nuclei with accelerated particles.
1938 Otto Hahn and Fritz Strassman achieved fission of the uranium atom.
1942 Enrico Fermi and associates achieved the first controlled nuclear chain reaction.
1947 John Bardeen, Walter H. Brattain, and William Shockley of Bell Telephone Laboratories invented the transistor.
1960 Theodore H. Maiman built the first laser.
1964 Murray Gell-Mann and George Zweig proposed the existence of quarks as fundamental particles.
1974 Burton Richter and Samuel C. C. Ting discovered a type of subatomic particle called the *psi particle* or *J particle.*
1983 Researchers led by Carlo Rubbia discovered two types of subatomic particles—the W particle and the Z particle.
1995 Fermi National Accelerator Laboratory announced the discovery of a type of subatomic particle known as the *top quark.*
2000 Fermi researchers announced the first direct detection of a kind of subatomic particle called the *tau-neutrino.*

argued that light traveled in the form of waves, rather than particles. But during the 1700's, most scientists accepted Newton's particle theory.

Developments in the 1800's. The Industrial Revolution, which had begun in Great Britain in the 1700's, led to the production of scientific instruments that were extremely accurate for their time and which enabled scientists to perform more complicated experiments. As scientific research grew more complex, people began specializing in more narrowly defined areas of study. Three areas of particular interest in the 1800's were heat and energy, light, and electricity and magnetism.

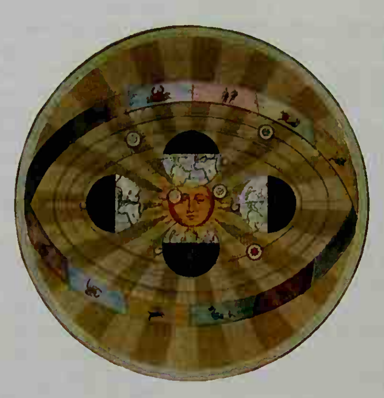
Developments in the study of heat and energy. At the beginning of the 1800's, it was widely believed that heat existed in the form of a fluid, called *caloric.* But by the middle of the century, scientists had come to view heat not as a fluid, but as a form of energy. That is, they had learned that heat is able to do work. In the 1840's, James Joule, an English physicist, showed how to calculate how much work a given quantity of heat could do. About the same time, a number of physicists, including Lord Kelvin of Great Britain and Hermann von Helmholtz of Germany, independently proposed the law of conservation of energy. This law states that energy cannot be created or destroyed, only transformed from one kind to another. See **Energy** (The conservation of energy).

By the mid-1800's, heat energy also came to be interpreted as the mechanical movement of the atoms of which everything was made. This interpretation was based on the atomic theory proposed in 1803 by John Dalton, an English chemist.

Developments in the study of light. From 1800 to 1803, the English physicist Thomas Young published a series of papers, based on experiments he had done, that revived the theory that light existed in the form of waves. From about 1815 to 1819, Augustin Fresnel, a French physicist, provided still more evidence. By 1850, the wave theory of light was almost universally accepted, replacing Newton's particle theory.

The wave theory of light led physicists to propose tl existence of a material called the *ether.* They reasoned that if light traveled in waves and could travel through vacuum, there had to be some medium present to sup port the waves. They concluded that all space, includin vacuums, was filled with the ether. They interpreted light energy as simply the vibration of the ether, in the form of waves. See **Ether**.

Developments in the study of electricity and magnetism. In 1800, Count Alessandro Volta of Italy announced his invention of the first electric battery. This invention opened the way for new methods of studyin electrical effects. About 1820, two physicists, André Marie Ampère of France and Hans Christian Oersted o Denmark, showed that electricity and magnetism were related. In the early 1830's, the English physicist Micha Faraday and the American physicist Joseph Henry independently demonstrated how to produce electricity in changing magnetic field. Their demonstrations showe that mechanical energy could be converted into electr cal energy and suggested the principles behind the ge erator and the motor.



In the 1860's, the Scottish physicist and mathematici James Clerk Maxwell developed a theory that interpreted visible light as the movement of electromagnet waves. Maxwell predicted the possible existence of sir ilar electromagnetic waves that were invisible. Heinricl Hertz, a German physicist, detected such invisible *radi waves* in the late 1880's. Hertz's discovery eventually le to the development of radio, radar, and television. But also suggested that light, electricity, and magnetism were related. All three were viewed as resulting from waves in the ether. Such waves are sometimes referre to as *electromagnetic radiation.*

The beginning of modern physics. Near the end the 1800's, many physicists were convinced that the work of physics was nearly over. They believed that almost all the laws governing the physical universe had been discovered. Some of them believed that all physi

Galileo in Italy discovered the law of fa ing bodies and the law of the pendulur In 1609, he began building telescopes t observe the heavens.

ıl laws would one day be expressed in a few simple ˌuations.

A few problems remained to be solved, however. ne such problem involved determining the source of ectromagnetic radiation. Scientists knew that under e right conditions, each chemical element radiates a ıique combination of visible, infrared, and ultraviolet ȷht, called *line spectra.* At the time, the atom was condered to be the most fundamental unit of matter in the ıiverse. But to some physicists, the line spectra pheɔmenon suggested that the atom might itself be comɔsed of still more fundamental units.

The dream of explaining all physical phenomena with ıe small set of basic laws was not realized. Instead, varus discoveries began to reveal that such phenomena ere more complex than scientists had thought. In 1895, r example, Wilhelm Roentgen of Germany discovered rays. In 1896, the French physicist Antoine Henri Becıerel discovered *natural radioactivity,* the spontaneous ıission of radiation from atoms. In 1897, the English ıysicist Joseph John Thomson discovered the first subomic particle, later called the *electron.* In 1898, the ench physicists Marie Curie and her husband, Pierre, scovered the radioactive element radium. Such develɔments signaled that, rather than being nearly over, e work of physics had only begun.

Quantum theory. The early 1900's brought revoluɔnary developments in physics. Scientists looked for consistencies in the classical physics of Newton and hers, and discovered new interpretations of observed ents.

In 1900, the German physicist Max Planck published s quantum theory of energy transfer to explain the ıectrum of light emitted by certain heated objects. He ated that energy is not given off continuously, but in e form of individual units called *quanta.* In 1905, Albert nstein, the German-born American physicist, proɔsed a new particle, later called the *photon,* as the carər of electromagnetic energy. Einstein said that light, in spite of its wave nature, must be composed of these energy particles.

In 1913, the Danish physicist Niels Bohr explained in terms of quanta how atoms absorb and radiate energy. In 1924, Louis de Broglie, a French physicist, proposed that electrons could also exhibit wave properties. In the mid-1920's, two physicists, Erwin Schrödinger of Austria and Werner Heisenberg of Germany, produced separate, but equivalent, systems for organizing all earlier quantum physics. The combined ideas of Schrödinger and Heisenberg have since been developed as the field of *quantum mechanics.* See **Quantum mechanics.**

Einstein and relativity. During the 1800's, physicists tried unsuccessfully to measure the speed of the earth relative to the ether. According to classical physics, the ether was motionless. In the early 1880's, Hendrik A. Lorentz, a Dutch physicist, explained the failure of these experiments by assuming that the ether was partially dragged along as the earth moved through it. Two American physicists, Albert A. Michelson and Edward W. Morley, developed an instrument that made far more precise measurements than earlier devices. Their experiments helped destroy the ether theory. In 1887, Michelson and Morley demonstrated that the earth's movement around the sun had no effect on the speed of light. Their finding could be understood only by assuming that the ether near the surface of the earth moved at the same speed as the earth. However, this assumption contradicted the results of many other experiments.

The contradiction was not resolved until 1905. That year, Albert Einstein analyzed the measuring process itself and, as a result, proposed his special theory of relativity. The theory begins with two *postulates* (fundamental principles). The first postulate states that for all observers moving uniformly relative to each other, the laws of physics have the same form. The second postulate states that for all observers, the speed of light is *invariant* (has the same value). One conclusion from these postulates is that mass and energy are related. Einstein

Marie Curie of France made many advances in the study of radioactivity. In 1898, she and her husband, Pierre, discovered the radioactive element radium.

expressed this relationship in his famous equation $E = mc^2$. In this equation, E stands for energy, m for mass, and c^2 for the speed of light multiplied by itself.

Einstein also attempted to replace classical gravitational theories with a more exact statement of the laws of gravitation. In 1915, he announced his general theory of relativity, which assumes that the effects of gravity on objects are identical to the effects of nongravitational forces acting on objects. Gravity is no longer viewed as a property of objects interacting with each other, but of objects interacting with space itself. The theory predicted that the path of a light beam will be affected by nearby massive objects. This prediction was confirmed in 1919. The theory also predicted the existence of *gravitational waves* that travel at the speed of light. But these waves have not yet been detected. See **Relativity.**

Uncovering the secrets of the atom. The discovery that atoms have an internal structure prompted physicists to probe further into these tiny units of matter. In England, Ernest Rutherford performed experiments that led to a model of the atom in 1911. In this model, the dense positive charge resided in a small, spherical core called the nucleus, and the electrons traveled around this nucleus. Bohr proposed modifications of the model in 1913. That year, an American, Robert Millikan, reported an accurate measurement of the electron's charge. See **Atom.**

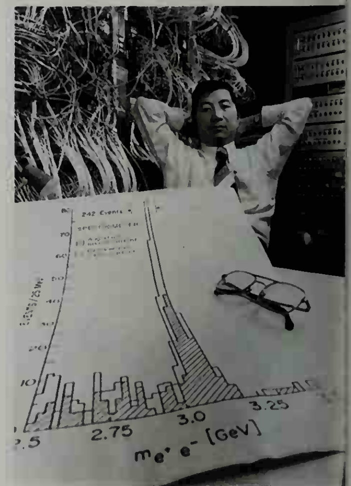
The discovery of other subatomic particles continued after this early work. In 1932, James Chadwick, an English physicist, conducted experiments that suggested that the atomic nucleus was composed of two kinds of particles: positively charged protons and neutral neutrons. In 1935, Hideki Yukawa, a Japanese physicist, proposed that other particles, which he called *mesons,* exist in the atomic nucleus (see **Meson**).

In 1938, two German physicists, Otto Hahn and Fritz Strassman, discovered nuclear fission by splitting uranium atoms. Scientists quickly realized that, as Einstein's formula $E = mc^2$ indicated, fission could liberate huge quantities of energy. In 1942, during World War II, the Italian-born physicist Enrico Fermi and his co-workers at the University of Chicago achieved the first controlled fission chain reaction. In 1945, near the end of the war, American scientists and engineers produced the first bombs that relied on nuclear fission for their explosive power. Two such atomic bombs were dropped on Japan in August 1945. See **Nuclear energy** (The development of nuclear energy); **Nuclear weapon.**

Advances in the mid-1900's. After 1945, the picture of the atom grew more complicated as physicists discovered more and more subatomic particles. In 1955, the American physicists Owen Chamberlain and Emilio Segre discovered the *antiproton* (a negatively charged proton). In 1964, two California Institute of Technology physicists, the American Murray Gell-Mann and Russian-born George Zweig, proposed the existence of *quarks* as fundamental particles. Protons and neutrons are composed of different combinations of quarks. Strong evidence for the existence of the quark resulted from the discovery of the *psi particle,* a type of subatomic particle also called the *J particle,* by the Americans Burton Richter and Samuel C. C. Ting. By 1995, scientists had discovered six types of quarks. Physicists are almost certain that there are no more quarks to discover. See **Antimatter; Psi particle; Quark.**

Research in the mid-1900's also led to important advances in technology. In 1947, American physicists invented the transistor. This tiny device revolutionized the electronics industry. In the early 1960's, researchers in atomic and optical physics produced light-amplifying devices called lasers. Lasers have become valuable tools in such areas as communications, industry, and nuclear energy research. See **Laser; Transistor.**

Physics today. Physics continues to be one of the most active and important sciences. Ongoing research into the nature of matter has led to important discoveries. For example, researchers in West Germany discovered an important elementary particle, the *gluon,* in



UPI/Bettmann Newsphotos

Albert Einstein proposed the special theory of relativity in 1905. It revised ideas of time and space and provided the basis for releasing the atom's energy.

Hughes Aircraft Company

Theodore H. Maiman of the United States built the first laser, a ruby laser, and first operated it in 1960. A laser amplifies light into a powerful beam.

Brookhaven National Laboratory

Samuel C. C. Ting, *shown here,* and Burton Richter of the United States discovered a new type of subatomic particle—the *psi,* or *J, particle*—in 1974.

1979. Gluons carry the *strong nuclear force.* This force, also called the *strong interaction,* holds quarks together in protons, neutrons, and other particles; and holds protons and neutrons together in atomic nuclei. In 1983, a research team led by Carlo Rubbia of Italy discovered two more subatomic particles—the *W particle* and the *Z particle.* Physicists predict that these particles are a source of the *weak nuclear force,* or the *weak interaction.* This force controls the disintegration of some atomic nuclei—a process at work in radioactivity.

Physicists believe that six kinds of quarks exist. The last of these to be discovered was the *top quark.* Scientists at Fermi National Accelerator Laboratory (Fermilab) near Batavia, Illinois, announced the discovery of this particle in 1995. Physicists also believe that there are three types of *neutrinos,* particles that interact with other particles by means of the weak nuclear interaction. The last kind of neutrino to be directly detected is known as the *tau-neutrino.* In 2000, researchers at Fermilab announced that they had made the first direct detection of tau-neutrinos.

There may be an underlying unity among three of the basic forces of the universe: the strong force, the weak force, and the electromagnetic force that holds electrons to the nucleus. Theories that attempt to establish this underlying unity are referred to as *grand unified theories* (GUT's).

Physics also continues to make important contributions to technology. For example, advances in electronics resulted in the development of extremely sophisticated computers. Lasers and *optical fibers* (glass or plastic filaments that carry light) led to improvements in communication systems and medical technology (see **Fiber optics**). Physicists began developing ceramiclike materials that can act as superconductors at much higher temperatures than the superconductors of the past.

Careers in physics

Education and training. A person who plans to pursue physics as a career should take science and mathematics courses in high school. The formal training of physicists begins in college. Physics students must learn calculus, modern algebra, and other forms of higher mathematics. They also take basic courses in chemistry. After a year or two of introductory courses, physics majors begin to specialize, taking more advanced courses in the various subfields of physics. Many of these advanced courses include intensive laboratory work.

Most physics majors continue their education beyond the bachelor's degree. A majority pursue doctor's degrees.

Employment. More than half the physicists in the United States are engaged in research and development activities. Many industries employ physicists in their research departments. These people often work in *applied physics,* which generally involves improving manufacturing processes or products. Many physicists are employed by colleges and universities. They generally divide their time between teaching classes and performing research.

Today, physics research often requires the use of highly specialized and expensive instruments and equipment, such as high-energy particle accelerators. In the United States, special laboratories with this type of equipment are funded by government agencies (see **National laboratory**). An association of European nations now known as the European Organization for Nuclear Research (CERN), established the world's largest particle physics research center, near Geneva, Switzerland. Although the U.S. national laboratories and the CERN laboratories have their own staffs, physicists throughout the world may apply to use the facilities in their research.

Physiocrats were a group of French economists wh lived during the mid-1700's. They made important con tributions to the development of economics as a socia science. The physiocrats' broad outlook and use of the scientific method made them the first modern thinkers in economics.

The physiocrats believed that land was the single source of wealth. They thought that only in agriculture could the value of the products exceed the value of th materials used for production. Physiocrats regarded in dustry and trade as necessary occupations, but ones t did not increase wealth in the same way as did agricul ture. Trade and commerce, they felt, changed only the form or location of wealth. These beliefs led the physiocrats to oppose the mercantile system of tariffs and trade restrictions. Mercantilists thought that a government should regulate economic activities in order to e sure that the country exports more goods than it imports (see **Mercantilism**). In place of tariffs, the physiocrats proposed a single land tax. They supporte *laissez faire* (freedom from government regulation).

François Quesnay was the leader and most importa thinker of the physiocrats. He devised the *Tableau Éco nomique,* a chart of the economy. This was the first attempt to picture a nation's economy as an interrelated series of institutions through which capital moves in a continuous cycle. Another physiocrat, Pierre Samuel

du Pont de Nemours, later emigrated from France to the United States, where his descendants founded the Du Pont industrial empire. Leonard S. Silk

See also **Du Pont de Nemours, Pierre Samuel; Quesnay, François.**

Physiology is the study of how living things function. Scientists who study physiology are called *physiologists.* Their studies range from the most basic unit of organisms, the cell, to complex organs and organ systems, such as the brain and digestive system.

Physiologists study how different parts or organs of an organism work together to achieve a particular function. In people, for example, the digestion of food involves the action of hormones and other chemicals produced by the stomach, liver, and pancreas. Muscle contraction occurs through the action of chemical messengers produced by nerves that supply the muscle.

By learning how the body functions normally, physiologists and doctors are better able to understand what happens when organs function abnormally. They can then prescribe the best treatment. For example, the thyroid gland uses iodine to make *thyroxine,* a hormone that affects the entire body. If iodine is too low in the diet, the thyroid gland expands, forming a large mass called a *goiter.* This condition can be corrected by including iodine in the diet (see **Goiter**). Studies of the circulatory and nervous systems have helped doctors understand and treat heart disease, stroke, and high blood pressure. Cell physiologists, who study the properties of individual cells, hope to learn what causes some cells to become cancerous. P. Landis Keyes

Pi, *py,* is the ratio of the circumference of a circle to its diameter. This ratio is the same for every circle and is approximately 3.14159. It is represented by the Greek letter π (pi).

Pi is used in a number of mathematical calculations. For example, the circumference *(c)* of a circle can be determined by multiplying the diameter *(d)* of the circle by pi: $c = \pi d$. Pi is also used to calculate the areas of circles and the volumes of spheres and cones. The area *(A)* of a circle is given by the formula $A = \pi r^2$, where r is the radius. In addition, a number of formulas that describe such physical phenomena as the motion of a pendulum or the vibration of a string include pi as well.

Pi is an *irrational number.* An irrational number cannot be written as a simple fraction or as a decimal with a *finite* (limited) number of decimal places. Mathematicians have used computers to calculate pi to millions of decimal places. Thomas P. Carpenter

See also **Circle** (The use of pi; History).

Piaf, *PEE ahf,* **Edith** (1915-1963), was a French singer whose frail appearance, difficult life, and haunting singing style made her a legend in France.

Piaf's real name was Edith Giovanna Gassion. Her father was a noted acrobat. Piaf's mother deserted her as an infant. The girl went blind for a short time about the age of 4, probably as a result of an infection. She received little formal education. As a child, Piaf traveled with her father as a singer and his assistant. At the age of about 15, she began singing on the streets and in cheap cabarets. One proprietor named her "Piaf," which was Parisian slang for "little sparrow." The nickname suited her delicate, childlike appearance. She was only 4 feet 10 inches (147 centimeters) tall and weighed about 90 pounds (41 kilograms).

UPI/Corbis-Bettmann

Edith Piaf

Tragedy marked Piaf's personal life. Her only child died in infancy. A man she loved, French boxer Marcel Cerdan, was killed in a plane crash. Such misfortunes were reflected in the sad and nostalgic ballads she sang, some of which she composed. Her most famous song was "La vie en rose." Gerald Bordman

Piaget, *PEE uh ZHAY,* **Jean,** *zhan* (1896-1980), a Swiss psychologist, won fame for his studies of the thought processes of children. He and his associates published more than 30 volumes on this subject.

Piaget believed children pass through four periods of mental development. During the *sensorimotor period,* they obtain a basic knowledge of objects through their senses. This period lasts until about age 2. During the *preoperational period,* from about 2 to 7, children develop such skills as language and drawing ability. In the *period of concrete operations,* from about 7 to 11, they begin to think logically. For example, they learn to organize their knowledge, classify objects, and do thought problems. The *period of formal operations* lasts from about 11 to 15. At this time, children begin to reason realistically about the future and to deal with *abstractions.* Abstractions are ideas about qualities and characteristics viewed apart from the objects that have them.

Piaget was born in Neuchâtel. When he was 10, he published a scientific article on an albino sparrow. He published articles on mollusks at 15. He received a doctor's degree in the natural sciences in 1918 and then studied psychology. In 1921, Piaget began to do research in child psychology at the Institute J.-J. Rousseau in Geneva. He served as its codirector from 1933 to 1971 and as director of the International Bureau of Education from 1929 to 1967. Piaget was a professor of psychology at the University of Geneva from 1929 until his death. In 1955, Piaget founded the Center for the Study of Genetic Epistemology, an organization that studies learning processes. Robert C. Weyant

Piano is a keyboard musical instrument in which sounds are made by strings struck by small padded hammers. A piano produces a greater range of musical sounds than most other instruments. On a piano, a musi-

Chicago Musical College (WORLD BOOK photo)
Grand pianos, such as the one shown above, are the largest and most expensive pianos. Performers use them in concerts.

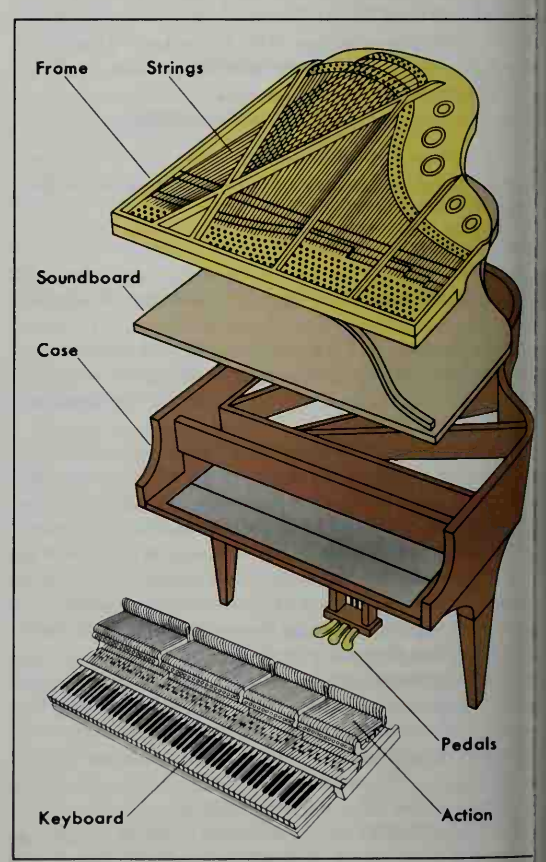
cian can play melody and harmony at the same time. A pianist also can play an extraordinary variety of loud and soft notes with great speed.

A musician plays a piano by striking keys of the keyboard. The keys operate levers that move the padded hammers. The hammers strike tightly stretched metal strings, which are mounted on a frame. These metal strings vibrate and therefore produce tones. The loudness of a tone depends on how hard the pianist strikes the keys.

The piano is important in many kinds of music. Most classical composers have written music for the piano as a solo instrument and in combination with other instruments or with singing. The piano is also used in jazz, rock, and other kinds of music.

Parts of a piano

A standard piano has seven main parts: (1) strings, (2) keyboard, (3) action, (4) pedals, (5) frame, (6) soundboard, and (7) case. The case covers the strings, action, frame, and soundboard. The keyboard and pedals are attached to the outside of the case.

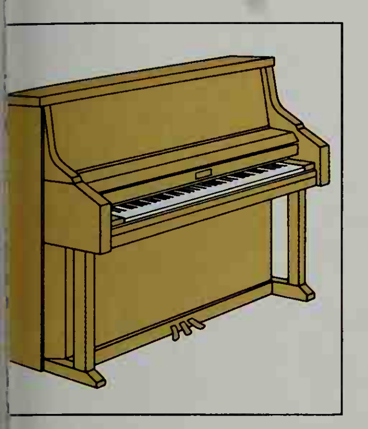


The strings. In almost all pianos, the strings are made of steel. Most pianos have more than 220 strings, each tuned to one of 88 pitches. The strings vary in length from 6 to 80 inches (15 to 200 centimeters). They are arranged in ascending order from left to right by *semitones,* or *half steps.* The longest strings are lowest in pitch and form the *bass section,* which occupies the left side of the piano. The shortest strings are highest in pitch and form the *treble section,* which occupies the right.

The pitch of a tone is determined mainly by the length of the strings. However, it also depends on the number, thickness, and *tension* (tightness) of the strings that produce each tone. About 58 tones, called *unisons,* have three strings each, and almost all the rest have two strings. In most cases, heavy strings are used for the low tones, and light strings for the high ones. The tension of the strings is adjusted when tuning a piano. Loosening string lowers the pitch, and tightening a string raises i

The keyboard. A standard piano keyboard has 88 keys. Like the strings, the keys are arranged according to pitch, in ascending order from left to right. On mos pianos, 36 keys are black, and 52 are white. The black keys are shorter and thicker than the white ones. Mos pianos have plastic keys. But on some pianos, the whi keys are made of ivory, and the black ones of ebony.

The action is an elaborate system of mechanical de vices that transmit motion from the keyboard to the strings. The pianist starts the action by striking a key, which causes a system of levers to move a hammer. Tl hammer is made of wood and covered with a special kind of felt. The hammer strikes a string, which vibrate and so produces a tone. When the player releases the key, a device called the *damper* presses against the string and stops its movement. If the pianist holds the key down, the damper remains off the string, allowing to vibrate and produce a tone. A piano's action consis of about 4,000 parts, most of which are made of wood



The pedals are located below the keyboard at the bottom of the piano. They are used to vary the quality tones played. The pianist operates the pedals with his her feet. Most pianos have a *damper pedal* on the rigl and a *soft pedal* on the left. The damper pedal lifts all

Electronic piano

ıe dampers, allowing the strings that are struck to vi-rate freely. The soft pedal shifts the hammers, which e arranged in a row. As a result, each hammer strikes ıe less string than it normally does, which softens and ghtens the tone. Some pianos also have a *sostenuto edal.* This pedal lifts the dampers from strings selected / the player.

The frame. A piano requires a strong frame to sup-ort the tremendous tension created by the stretched rings. The frame is made of cast iron. It withstands the rain of 220 strings exerting a total pull of from 35,000 45,000 pounds (15,900 to 20,400 kilograms).

The soundboard is a thin sheet of wood that helps inforce the sound created by the vibrating strings in a ano. The soundboard lies just below the strings and is ade of a light wood, generally spruce. The wood vi-ates with the strings, intensifying the sounds.

The case. Most pianos have a wooden case, which vers the strings, action, frame, and soundboard. The se must be strong enough to support the weight of e piano.

Kinds of pianos

There are four basic kinds of pianos: (1) grand pianos, upright pianos, (3) player pianos, and (4) electronic pi-os. The four types vary in size and construction and e used for different purposes.

Grand pianos are mounted on legs, and their strings d soundboard are parallel to the floor. The *concert and* is the largest and most expensive piano. It meas-es about 9 feet (2.7 meters) long and is used in concert lls. The *parlor grand* and the *baby grand* measure be-een 5 and 6 feet (1.5 and 1.8 meters) long and are suit-le for homes.

Upright pianos are sometimes called *vertical pianos* cause their strings and soundboard are perpendicu-to the floor. These pianos take up less floor space— t also have poorer tone quality—than grand pianos. ere are three main kinds of upright pianos, the *spinet, console,* and the *studio.* A spinet stands between 36 d 38 inches (91 and 97 centimeters) high. A console asures between 36 and 40 inches (91 and 100 centi-meters) high, and a studio between 45 and 50 inches (114 and 130 centimeters) high.

Player pianos produce music automatically. They are operated by a roll of paper with patterns of holes that correspond to different notes. The roll moves over a cylinder, which also has small holes. A system consisting of a pump, bellows, and valves creates a vacuum in the cylinder. This vacuum sucks a stream of pressurized air through matching holes in the moving roll and the cylinder. The pressurized air causes the piano's hammers to move and strike the strings, producing music. Player pianos were popular during the late 1800's and early 1900's. The performances of many great pianists of that period have been preserved on player rolls.

Electronic pianos are often used in jazz and rock music. In one kind of electronic piano, the sound of the hammer striking the strings is picked up by a microphone and amplified electronically. The most popular type has no strings at all. Instead, all sound is produced by electronic means. This kind of electronic piano is small enough to carry, but it produces enough sound to fill a large auditorium. Both types have a keyboard. The number of keys varies from 54 to 88.

History

Several musical instruments, including the *dulcimer, clavichord,* and *harpsichord,* were forerunners of the piano. The dulcimer was probably invented in the Middle East during ancient times. It consists of a flat box with a set of wires across the top. The instrument is played by striking the wires with a mallet. The clavichord and harpsichord, which were developed by Europeans during the Middle Ages, were among the first string instruments with a keyboard.

In 1709, Bartolommeo Cristofori, an Italian who built musical instruments, invented a keyboard instrument with strings that were struck by hammers. Cristofori gave his invention the name *gravicembalo col piano e forte,* which means *harpsichord with soft and loud.* The name was later shortened to *pianoforte.* Cristofori's instrument was the direct forerunner of the modern piano.

The Metropolitan Museum of Art, New York City,
The Crosby Brown Collection of Musical Instruments, 1889

The pianoforte was the earliest piano. Bartolommeo Cristofori invented it in 1709. He made the one shown here in 1720.

Between the late 1700's and early 1800's, several musical instrument makers improved upon Cristofori's pianoforte. In the late 1700's, John Broadwood of England made many improvements in the piano. Broadwood's instrument produced louder and richer tones than the pianoforte. In 1821, Sébastien Érard of France designed the *double escapement,* a device that improved the action of the piano's hammers. Alpheus Babcock, an American, invented a large cast-iron frame in 1825. He also developed a method of cross-stringing pianos. In 1855, Henry E. Steinway, a German-born piano maker who moved to the United States, combined all these inventions in one piano. His piano closely resembled the grand pianos built today.

Since the late 1700's, most great classical composers have written music for the piano. Leading composers of piano music in the late 1700's and the 1800's included Ludwig van Beethoven, Johannes Brahms, Frédéric Chopin, Joseph Haydn, Franz Liszt, Wolfgang Amadeus Mozart, Franz Schubert, and Robert Schumann. Many classical composers of piano music, including Liszt and Chopin, were also accomplished players.

During the 1900's, leading composers of piano music included Béla Bartók, Claude Debussy, Paul Hindemith, and Maurice Ravel. Some American composers introduced major changes in piano music. For example, Henry Cowell introduced groups of notes called *tone clusters,* which are played with the palm, fist, or forearm. Cowell also called for pianists to strum the piano strings with their fingers. John Cage devised the *prepared piano,* in which paper clips, thumbtacks, and other objects are inserted between some of the strings. When the pianist strikes the keys for these strings, unusual sounds are produced. George Crumb electrically amplified the sound of the piano.

The leading pianists of the 1900's included Daniel Barenboim, Ferruccio Busoni, Van Cliburn, Glenn Gould, Myra Hess, Vladimir Horowitz, Sergei Prokofiev, Sergei Rachmaninoff, Arthur Rubinstein, and Rudolf Serkin. A few pianists of the 1900's, including Busoni, Prokofiev, and Rachmaninoff, also composed great piano music. F. E. Kirby

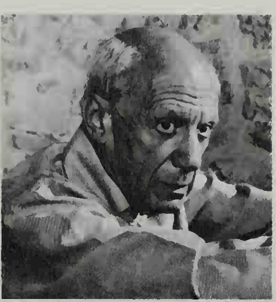
Piatigorsky, *pyah tih GAWR skee,* **Gregor,** *GREHG uhr* (1903-1976), was a famous Russian-born cellist. His playing established him as one of the great cellists of his time. Piatigorsky collaborated in the 1960's with violinist Jascha Heifetz and violist William Primrose. These collaborations set the highest standards for chamber-music performance.

Piatigorsky was born on April 17, 1903, in Ekaterinoslav (now Dnepropetrovsk, Ukraine). He made his American concert debut in 1929 and became a United States citizen in 1942. Piatigorsky became an important teacher, settling in Los Angeles, California. While Piatigorsky was there, he spent time teaching master classes at the University of Southern California from 1962 until his death. Stephen Clapp

Picador. See Bullfighting.



Picasso, *pih KAH soh,* **Pablo** (1881-1973), was the dominant figure in art of the 1900's. Picasso was primarily a painter, but he also exerted a great influence on printmaking, sculpture, ceramics, drawings, and designs for the theater. All modern artists have been influenced by Picasso's work, either directly or indirectly.

Early life. Pablo Ruiz Picasso was born on Oct. 25, 1881, in Malága, Spain. In 1895, after living in La Coruña for nearly four years, his family moved to Barcelona. Picasso learned the basic skills of painting from his father, José Ruiz Blanco, an artist and art teacher. In 1897 and 1898, Picasso lived in Madrid, where he spent much

Pablo Picasso was the dominant artist of the 1900's. *Family of Saltimbanques* is the masterpiece of Picasso's Rose Period, which began in late 1904. The large painting portrays a group of traveling acrobats. The figure on the left, dressed as the clown Harlequin, is a self portrait of the artist. The rose and pink colors of the painting are typical of Picasso's style during this period.

me in the Prado museum studying paintings by the reat artists who lived before him. He returned to arcelona in 1899.

The Blue Period. Picasso's artist friends in Barcelona ventually introduced him to the art world in Paris. He iade several lengthy visits to Paris before settling there ermanently in 1904. From 1901 to 1904, he developed a yle known as his Blue Period. During this period, Picas- painted primarily in blue colors, evoking a feeling of idness and alienation. A classic of the period is *The ld Guitarist* (1903), which appears in the **Color** article in *Vorld Book*. It is typical of Picasso's subjects during this eriod, which featured the poor of Paris, such as beg- irs and starving children. The guitarist's stretched-out, storted body and impossibly long fingers indicate the fluence of El Greco, a painter who worked in Spain uring the late 1500's and early 1600's.

After Picasso finally settled in Paris, he moved into a nement in the Montmartre section, nicknamed the *iteau Lavoir* (Laundry Boat) for the laundry barges that ocked on the Seine River there. He lived in the Bateau voir until 1909, with a growing circle of friends, no- bly painters, poets, actors, and critics.

The Rose Period. In late 1904, Picasso expanded his lection of colors, emphasizing rose and pink. At the me time, he eased the sadness of his subjects. This w style, called the Rose Period, concentrated on acro- ts who traveled from town to town. They were called *ltimbanques* and often featured the *harlequin* asked clown) and other characters who were popular the traditional Italian theater *commedia dell'arte* and pantomimes. Picasso often visited the Cirque Médrano near his Montmartre studio, which stimulated his interest in circus subjects. The appearance of circus figures in Picasso's art coincided with his friendship with the French poet Guillaume Apollinaire, whose verse is filled with references to harlequins and saltimbanques as symbols of both friendship and alienation.

The masterpiece of the Rose Period is *Family of Saltimbanques* (1905). At about 7 feet (2.1 meters) high and 7.5 feet (2.3 meters) wide, it was the largest painting of both the Blue and Rose periods. The painting displays almost no activity. The characters hardly notice each other. The stillness of the scene lends it mystery and a sense of melancholy. Picasso portrayed himself as Harlequin, as he did in many paintings. With the self portrait, this painting reflects Picasso's sense of artistic isolation or alienation. *Family of Saltimbanques* includes one figure thought to be from the Cirque Médrano, El Tío Pepe, a fat man in a bright red suit. The identity of the remaining figures remains controversial. Some scholars believe they represent Picasso's friends of the time.

Before Picasso completed *Family of Saltimbanques*, his work came to the attention of the American writer Gertrude Stein. Stein had lived in Paris since 1903 and was building one of the foremost collections of modern art in Paris. She met Picasso in 1905 and introduced him to the French painter Henri Matisse in 1906.

Early sculptures. In the summer of 1906, Picasso traveled to Gósol, a remote village in the Pyrenees mountains. Before he left for Gósol, he had discovered sculpture of the Iberian peninsula (present-day Spain and Portugal) from the 500's and 400's B.C. Under the influence of ancient Iberian sculpture, Picasso began to ex-

periment with distortion as an expressive element.

At the 1906 annual exhibition in Paris, called the Salon d'Automne, Picasso saw the work of the French artist Paul Gauguin in carved wood along with 10 paintings by the French painter Paul Cézanne. The achievements of these two artists and his response to them preoccupied Picasso over the next year or so and helped define his later work. Gauguin's use of forms found in the Pacific Islands, especially Tahiti, provided Picasso with an important model for using the art of non-Western cultures in his work.

Upon his return to Paris after that summer, Picasso completed a portrait of Gertrude Stein, begun months earlier. He gave the portrait a sculpturelike appearance by painting Stein with a masklike face and massive body of monumental chiseled forms.

Les Demoiselles d'Avignon is a large painting Picasso completed in 1907. Many art historians consider it the most influential painting of the 1900's because it opened the way to modern art. The painting appears in the **Cubism** article. The picture portrays five *demoiselles* (young women), prostitutes from Avignon Street in Barcelona, which Picasso knew well. Picasso reduced the figures to a series of interlocking, angular shapes. He filled the composition with sharp planes, distortions of space, and deliberately disorienting and contradictory points of view. Picasso used this distortion of the female form to express his anxieties about women, love, and sexuality. The painting reveals Picasso's attempt to harness the forms of non-Western carving and the power of magic and ritual in African art.

Cubism. Picasso and the French artist Georges Braque became acquainted in 1907, and a remarkable artistic dialogue between the two began in 1908. Together they produced a revolutionary style called Cubism, in which figures and objects are represented by geometrical forms.

In 1909, Picasso and Braque entered a period of great intensity in their work together. Their pictorial vocabularies merged in a phase called Analytic Cubism. Analytic Cubism broke down forms from the natural world and reassembled them into flat planes.

Oil on oilcloth on canvas edged with rope (1912) Musée Picasso, Paris (Art Resource © 2002 Estate of Pablo Picasso/Artists Rights Society (ARS), New York City)

Still Life with Chair Caning is a *collage*, a technique Picasso invented. He attached a piece of oilcloth printed with a pattern like chair caning and surrounded the painting with hemp rope.

During Picasso's Cubist period, he often painted *still lifes* (pictures of fruit, bowls, bottles, and other everyday objects). He drew his subjects from cafes and artist's studios, settings familiar to him. In 1912, the Cubist search for different styles of representation led Picasso to create *Still Life with Chair Caning*, and with it, to invent a technique called *collage*. Collage is a form of painting o drawing that attaches flat, readymade materials to the surface (see **Collage**). *Still Life with Chair Caning* shows objects scattered across a cafe table, including part of the newspaper *Le Journal*, a glass, and a lemon. To the painted objects, Picasso applied a real object, a piece of oilcloth printed with a pattern like chair caning. For a frame, Picasso surrounded the oval canvas with a length of thick hemp rope to make the collage look like an old master painting.

Picasso also created illusions in his three-dimensional constructions, beginning in 1912 with a series of sculptures called *Guitar*. One of these works appears in the **Sculpture** article. This *Guitar*, which Picasso completed in 1913, is constructed of sheet metal and wire. He cut away most of the guitar body and expressed its shape as a series of flat, projecting planes. He made the guitar's sound hole a projecting cylinder. In a real instrument, the hole would be an open space. Picasso's use of sheet metal, an industrial material, was highly unusual at that time, but such materials have since become common sculptural mediums. His invention of this radical new sculptural form had a great influence on later developments in sculpture.

By 1912, Picasso discovered that he could give shapes different meanings—real or abstract—simply by rearranging them. He also found that he could use a variety of materials on surfaces. Collage and the *Guitar* construction essentially ended Picassso's Analytic Cubist phase, and he began a second phase, called Synthetic Cubism, which lasted into the early 1920's. Synthetic Cubism generally constructed an image from many components. Instead of dissecting forms, as in Analytic Cubism, the artist added elements to the picture surface, building up the image through each addition, as Picasso did in *Still Life with Chair Caning* (1912).

When France joined World War I shortly after it began in 1914, Braque was called into the French military. Because Spain remained neutral during the war, Picasso continued working on art, but his collaboration with Braque came to an end.

Picasso as designer. A friendship with the French writer Jean Cocteau brought Picasso into the social circle surrounding the Ballets Russes in 1919. The Ballets Russes was a touring Russian dance company that included some of the greatest dancers, composers, and artists of the time. The first ballet Picasso became involved was *Parade*. Cocteau created the story, and Picasso designed the curtain, sets, and costumes. *Parade* premiered in 1917. Critics considered the ballet a radical break from traditional ballet, largely due to Picasso's designs. He continued to work on ballets until 1924, while also painting such Synthetic Cubist works as *Three Musicians* (1921).

The 1920's and 1930's. Picasso began to work in a different style in the 1920's, one he practiced alongside Cu

Guernica (1937), an oil painting on canvas; the Reina Sofia Museum, Madrid (MAS © Artists Rights Society, New York City)

uernica is one of Picasso's most powerful paintings. The artist painted this work as a protest against e bombing of the Spanish town of Guernica in 1937. Such images as a gored horse, a woman with a ead child, and a fallen soldier became emotional symbols of the bitter suffering of wartime.

sm. This style was his version of Neoclassicism in- ɔired by a trip to Italy in 1917. The artist began to use lassical forms and drawing techniques, reflecting the fluence of Mediterranean culture. *Three Women at the ɔring* (1921) shows its Classical roots in the facial fea- res and clothing of the large, serene figures.

Picasso never became an official member of the Sur- alist group during the 1920's, but he had close con- ections with several Surrealist members. The Surreal- ts used unexpected arrangements and distortions of nages to reflect dreams and the subconscious mind ee **Surrealism**). The Surrealist movement gave Picasso ew subjects. It also reinforced his interest in the frag- entation of forms and the expression of suppressed notions, qualities dating back to *Les Demoiselles d'Avi- ɔon*. Picasso's own brand of Surrealism also found a ique expression in poetry. He began to write in the ll of 1935 and continued into 1936. During that time, he ncentrated on poetry instead of painting.

In the mid-1930's, Picasso resumed painting with a ew political commitment. The outbreak of the Spanish vil War in 1936 stirred Picasso to produce work sup- ɔrting the cause of the Spanish Loyalists against the scists led by Francisco Franco.

The weakened Spanish Loyalist government asked Pi- sso to paint a mural for the Spanish Pavilion at the ris world's fair in 1937. The artist struggled to find a bject for the mural until he was inspired by the bomb- g of the Spanish town of Guernica, ordered by Franco. amatic photographs of the destruction of the small wn gave Picasso his subject matter.

Picasso painted *Guernica* in about a month in 1937. e canvas stretches more than 25.5 feet (7.8 meters) in ngth. The imagery of *Guernica*—a gored horse, a ɔman with a dead child, a fallen soldier—became werful symbols of bitter suffering. To dramatize the rtime agony of destruction, the artist restricted his lors to stark black, white, and gray.

Later career. After Germany invaded France in 1940, casso lived in his Paris studio, though he was banned from showing his work. Skulls began to appear in some of his paintings. They symbolized the tragedies that had touched the artist, including World War II (1939-1945), his mother's death in 1939, and the death of his friend, the Spanish sculptor Julio González in 1942.

After France was liberated in 1944, the Salon d'Automne of 1944 featured Picasso's work of the war years. These somber paintings shocked viewers, as did the announcement that Picasso had joined the French Communist party. His anti-American painting *Massacre in Korea* (1951) depicts American soldiers as medieval knights slaughtering innocent women and children.

From 1948, Picasso lived and worked in the south of France, at first for part of the year and later permanently. His international reputation had expanded, and his name had become virtually synonymous with modern art.

During the final two decades of his life, Picasso became fascinated with earlier art. He based paintings on works by two masters of the 1600's, the Dutch artist Rembrandt and the Spanish artist Diego Velázquez, and by French artists of the 1800's, including Eugene Delacroix and Edouard Manet. Picasso pitted himself in competition with his chosen masters, breaking their work down, recomposing it, and becoming ever bolder in his methods of painting.

Picasso's style continued to develop through the last decade of his life. At the time of his death on April 8, 1973, Picasso still owned hundreds of his own works in various mediums from all periods of his career. These pieces provided the basis of a gift to the French government by his heirs. In 1985 the Picasso Museum opened in Paris to display the works. Michael Plante

Piccalilli is a popular relish made from chopped and pickled cucumbers, other vegetables, and spices.

Piccard, *pee KAHR* or *pih KAHRD,* is the name of a Swiss family of scientists who won fame in aeronautics and oceanography. Auguste and Jean Piccard, twin brothers, were born in Basel, Switzerland, and were educated in Zurich. Jacques Piccard, the son of Auguste, was born in Brussels, Belgium, and graduated from the University of Geneva.

Auguste Piccard (1884-1962), a physicist, invented an airtight *gondola* (passenger compartment) that he attached to a huge hydrogen-filled balloon. In 1932, he and an assistant, Max Cosyns, ascended in it 53,152 feet (16,201 meters) into the stratosphere and gathered information on cosmic rays (see **Balloon** [Manned explorations of the stratosphere]). In 1948, Piccard designed a deep-sea diving ship called a *bathyscaph* (see **Bathyscaph**). In 1953, he and his son, Jacques, descended 10,300 feet (3,140 meters) into the Mediterranean Sea in a bathyscaph named the *Trieste.* Piccard taught physics at the University of Brussels from 1922 to 1954.

Jean Piccard (1884-1963) was an aeronautical engineer and chemist. In 1934, he ascended by balloon more than 57,500 feet (17,530 meters) to study cosmic rays. In 1937, he made an ascent in an open gondola lifted by 98 balloons that measured 6 feet (1.8 meters) in diameter. This flight was the first manned ascent to use multiple balloons. Piccard became a United States citizen in 1931. He taught aeronautical engineering at the University of Minnesota from 1936 to 1952.

Jacques Piccard (1922-) is an oceanographic engineer. In 1960, in the bathyscaph *Trieste,* he and Lieutenant Don Walsh of the U.S. Navy descended 35,800 feet (10,910 meters) into the Pacific Ocean. In 1969, Piccard designed a special underwater craft for studying ocean currents. That year, he and five other scientists traveled in it along the Gulf Stream, a large ocean current off the east coast of the United States. During the 1970's, Piccard studied the effects of pollution on ocean life. Daniel J. Kevles

Piccolo is the smallest of the woodwind instruments and the highest in pitch. It measures about 12 inches (30 centimeters) long.

The piccolo is a member of the flute family. It is about half the length of the common concert flute and is played in the same way (see **Flute**). The piccolo sounds an octave higher than the concert flute, producing a bright, penetrating tone. The piccolo came into use as an orchestral instrument in the late 1700's and early 1800's. The instrument is also used in concert and military bands. André P. Larson

For a recording of the sound of a piccolo, see the **Piccolo** article in the CD-ROM version of *World Book.*

Pichincha, *puh CHIHN chuh* or *pee CHEEN chah,* a twin-cratered volcano, rises 15,696 feet (4,784 meters) in the Andes Mountains in north-central Ecuador (see **Ecuador** [map]). It last erupted in 1881. Climbers may ascend the peaks from Quito, which is about 5 miles (8 kilometers) to the southeast. On Pichincha's lower slopes, patriot forces defeated the Spanish royalists in the Battle of Pichincha in 1822, thus liberating Ecuador.

Gregory Knapp

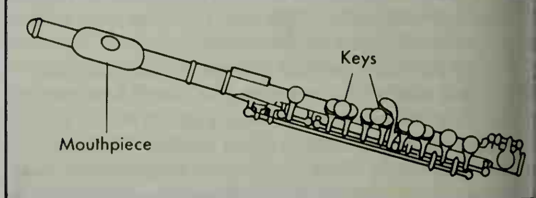
Pickaroon. See Pirate.

Pickerel, *PIHK uhr uhl* or *PIHK ruhl,* is the name given to three small members of the pike family. Like all pikes, pickerels have large mouths and greedy appetites. They fight stubbornly when caught on a hook. Pickerels live in fresh water. They usually eat smaller fish.

The three kinds of pickerel are the *redfin pickerel,* also called *bulldog pickerel,* which lives east of the Allegheny Mountains from Maine to Florida; the *grass pickerel,* or *mud pickerel,* which is found abundantly in the Mississippi Valley; and the *chain pickerel,* which lives in lakes and streams east and south of the Alleghenies, from Maine to Florida and west to Arkansas. The redfin

WORLD BOOK illustration by Colin Newman, Linden Artists Ltd

The chain pickerel is a popular freshwater game fish. It lives in lakes and streams in the Eastern and Southern United States.



pickerel and the grass pickerel seldom grow more than 1 foot (30 centimeters) long. The chain pickerel commonly reaches a length of about 2 feet (61 centimeters). However, it may grow to about 3 feet (91 centimeters) long. The chain pickerel weighs up to 10 pounds (4.5 kilograms). It is a popular game fish, and its flesh is good to eat. Robert D. Hoyt

Scientific classification. Pickerels are in the pike family, Esocidae. The scientific name for the redfin pickerel is *Esox americanus americanus;* the grass pickerel, *E. americanus vermiculatus;* and the chain pickerel, *E. niger.*

See also **Pike**.

The piccolo is the smallest of the woodwind instruments. A musician plays the piccolo like a flute, blowing across a hole in the mouthpiece while pressing keys that cover the tone holes.

ickering, John. See Impeachment (History).

ickering, Timothy (1745-1829), was a leading merican statesman. He served as postmaster general om 1791 to 1795, secretary of war in 1795, and secre-ry of state from 1795 to 1800. A member of the Federal-t Party, he represented Massachusetts in the United tates Senate from 1803 to 1811 and in the House of epresentatives from 1813 to 1817.

Pickering opposed the policies of Presidents Thomas fferson and James Madison. Beginning in 1804, he fa-ored unsuccessful plans to have New England secede om the Union. He was born in Salem, Massachusetts.

Richard D. Brown

icket. See Labor movement (Handling labor dis-utes; picture); Strike.

ickett, Bill (1870?-1932), was a famous African Ameri-n cowboy. As a working cowboy, he showed great ill at such jobs as branding, bronco riding, herding, nd roping. He went on to become a star rodeo per-rmer.

Pickett was born in Jenks-Branch, near Austin, Texas. is full name was Willie M. Pickett. By age 10, he had eveloped a unique style of bulldogging (now often illed steer wrestling). By 16, he was performing profes-onally. His bulldogging style involved leaping from his orse, grasping the steer by the horns, twisting its head oward, and biting its upper lip—forcing the animal on s side. This so-called "bite-em" style made Pickett the ar of the 101 Ranch Wild West Show, in which he per-rmed off-and-on from 1907 to the mid-1920's. He was lled as the "Dusky Demon." He performed before roy-ty in England.

Despite his stardom, Pickett was kept out of many ro-eos by racial discrimination. He worked as a cowboy n ranches throughout his rodeo career. Pickett died ss than a month after being kicked in the head by a orse he was trying to *break* (tame).

Nudie Eugene Williams

ickett, George Edward (1825-1875), was a Confed-rate general during the American Civil War (1861-1865). the Battle of Gettysburg in 1863, he took part in an un-ise charge that ranks as one of the most famous events American history. On July 3, Cemetery Ridge was a y to the Union Army's positions. Pickett's division and rts of other units charged up the hill in the face of avy fire and broke through a part of the Union lines. ldiers fought hand to hand. No help came to Pickett om the main Confederate lines, and at last the troops ll back after suffering ter-ble losses.

The failure of what be-me known as "Pickett's arge" ended the Battle of ettysburg, and General obert E. Lee retreated the xt day. The charge and e battle marked a turning int in the war. The Battle Gettysburg shattered the my of Northern Virginia, d the army never re-ined its former power. though Pickett continued command of his divi-sion, he was broken in spirit. He later served with General James Longstreet.

Chicago Historical Society
General George Pickett

Pickett was born in Richmond, Virginia, and graduated from the United States Military Academy in 1846. He served in the Mexican War (1846-1848) and on the Indian frontier. Pickett became a major general in 1862 and fought in the Battle of Seven Pines and at Fredericksburg. John F. Marszalek

See also **Gettysburg, Battle of.**

Pickett, Joseph (1848-1918), was an American folk artist. Pickett was a storekeeper, carpenter, and shipbuilder and painted only as a hobby. He had no art lessons. Pickett was born and lived in New Hope, Pennsylvania, where he found most of the subjects of his work. Only four of Pickett's paintings are known to exist.

Pickett's best-known painting, titled *Manchester Valley,* portrays New Hope High School. The painting shows Pickett's characteristic rich, vibrant color, complex line patterns, and thick, gritty textures. Pickett did not achieve recognition as a folk artist until after his death. Sarah Burns

Pickford, Mary (1893-1979), was a star of silent motion pictures. Pickford became known as "America's Sweetheart" because of her great popularity. She was famous for her portrayals of plucky and innocent young heroines.

Pickford made her film debut in 1909 and appeared in 194 movies. Among her most popular films were *The Poor Little Rich Girl* (1917) and *Rebecca of Sunnybrook Farm* (1917). Pickford won the 1928-1929 Academy Award as best actress for her performance in *Coquette.* She also received a special Academy Award in 1976 honoring her lifetime contribution to movies.

Bettmann Archive
Mary Pickford

Pickford was born in Toronto, Canada. Her real name was Gladys Marie Smith. She began acting on the stage at the age of 5. In 1919, she founded United Artists, a major Hollywood movie studio, with director D. W. Griffith and film stars Charlie Chaplin and Douglas Fairbanks, Sr. Pickford married Fairbanks in 1920. She retired from film acting in 1933.

James MacKillop

Pickle is a vegetable or fruit preserved in vinegar or some other food acid. Pickles may be either sweet or sour. They are made with or without sugar and salt and are usually seasoned with spices.

The most common vegetable for pickles is the cucumber. Other vegetables and fruits often used in making pickles or *relishes* (chopped pickles with a sweet seasoning) are cabbage, carrots, cauliflower, olives, onions, peaches, pears, green and red peppers, tomatoes, and watermelon rinds.

The process of pickling begins by soaking the vegetable or fruit in *brine* (salty water). The acid that is responsible for the preservation of pickles is then either added by the food processing company or is produced by

bacteria in the brined pickle. Bacteria produce this acid by means of *fermentation* (a breaking down of chemicals in the pickle). To aid preservation, the processor may also use refrigeration or *pasteurization* (heating to kill harmful bacteria), or the processor may add chemicals to the brine.

Pickles are flavored with various seasonings, such as allspice, bay leaves, celery seed, cinnamon, cloves, dill, garlic, horseradish, mustard, and peppercorn. Pigs' feet, hard-boiled eggs, and other foods can also be preserved in a pickling solution. Henry P. Fleming

Picotte, Susan La Flesche (1865-1915), was the first American Indian woman to become a physician. She earned an M.D. degree in 1889 from the Women's Medical College of Pennsylvania in Philadelphia. She graduated at the top of her class.

Picotte, a member of the Omaha tribe, worked to improve medical care on the Omaha reservation in northeastern Nebraska. From about 1891 to 1894, she was head physician on the reservation. She later organized a county medical society and headed the local board of health. In 1913, Picotte established a hospital on the reservation. The hospital was named for Picotte after her death.

Susan La Flesche was born on June 17, 1865, on the Omaha reservation and attended government and mission schools there. Her father, the chief of the Omaha tribe, believed that education was a key to success in America. She studied at the Elizabeth Institute for Young Ladies in Elizabeth, New Jersey, and graduated from Hampton Institute in Hampton, Virginia. In 1894, she married Henry Picotte, a farmer of French and Sioux Indian ancestry. W. Roger Buffalohead

Pictograph, *PIHK tuh graf,* is picture writing. Before the development of the alphabet, many ancient peoples conveyed messages by pictographs. The Egyptians carved or painted pictographs on tombs and monuments. In addition, picture writing was a means of communication for the Aztec and for the early American Indians. Pictographs were of two kinds: those that represented objects, such as a drawing of the moon, and those that represented ideas, such as a drawing of a child with a book, to represent a student. Pictographs today may be used to show numbers or to tell a story. See also **Alphabet; Aztec** (Language; picture); **Graph; Hieroglyphics.** Charles F. Sieger

Pictou, *PIHK too* (pop. 3,875), is a port town in Nova Scotia. It lies on the south shore of Northumberland Strait, an inlet of the Atlantic Ocean. For location, see **Nova Scotia** (political map). The town's chief industries include fishing, pulp and paper manufacturing, shipbuilding, steelmaking, and tourism. Pictou has a mayor-council form of government and is the seat of Pictou County.

Micmac Indians lived in the area of what is now Pictou before white settlers arrived in 1767. In 1773, a large ship brought nearly 200 settlers from Scotland to Pictou. During the early 1800's, thousands of Scots came to Nova Scotia through this port. D. A. Sutherland

Picts, *pihkts,* were an ancient people of northern Scotland. The Picts were given this name by the Romans because they painted or tattooed their skin. The Latin word for *painter* is *pictor.* The first historical reference to the Picts occurs in a speech made by a Roman orator in A.D. 297. The Pictish tribes fought the Romans for many years. The Romans built two long walls to keep the Picts out of the province of Britain. Later, the Picts fought the Teutonic conquerors of Britain, the Angles and Saxons. They disappeared as a people about A.D. 900. See also **Scotland** (The Roman invasion). Robert S. Hoyt

Picture writing. See **Hieroglyphics; Alphabet; Cuneiform; Pictograph.**

Pidgin English, *PIHJ uhn,* is one of several *bridge* or *minimum* dialects, based on English, used in Asia and the South Seas between Westerners and Asians, and among peoples who have no common tongue. The word *pidgin* comes from a change in the pronunciation of the word *business.*

Pidgin English is sometimes viewed as a corruption of English, but it serves the needs of millions of people who would be unable to communicate without it. The phrase *long time, no see* is an example of Chinese Pidgin. Robert J. Kispert

Piece of eight was a name for the Spanish *peso,* which corresponded to the American dollar (see **Peso**). It was so named because it was worth 8 *reals* and once had an *8* stamped on it. The piece of eight was sometimes cut into pie-shaped smaller denominations called *bits.* The most popular size was the quarter, called *two bits.* The United States quarter is sometimes called *two bits* today. The piece of eight was used when pirate activity was widespread. The coin figures in many pirate stories, including *Treasure Island.* Burton H. Hobson

WORLD BOOK photo by James Sime

A piece of eight. Coins of this sort, known also as "Spanish milled dollars," were once widely used in the Americas. They were called "pieces of eight" because they were worth eight *reals,* the *real* being valued at about 12 $\frac{1}{2}$ cents. The coin pictured here was minted in Mexico during the reign of King Charles III of Spain.

Pied Piper of Hamelin, *HAM uh lihn,* is a mythical character who was made famous by Robert Browning in a poem based on a legend. According to the legend, the German town of Hamelin (now Hameln) was infested by rats. One day, a man dressed in a suit of many colors walked into Hamelin and offered to rid the town of the pests for a sum of money. When the mayor agreed, the man drew out a pipe and walked along the streets playing a haunting tune. All the rats came tumbling out of the houses and followed the Piper to the Weser River, where they drowned. When the Piper claimed his reward, the mayor refused to pay him. The Piper swore vengeance. Once more he walked along the streets

laying his strange melody. This time all the children ran
om their homes and followed him to a cave in the
earby Köppen Hill. The cave closed upon them, and the
hildren were never seen again.

This legend seems to be based at least in part on fact.
ld writings on the walls of several houses in Hamelin
ıy that on July 26, 1284, a Piper led 130 children out of
wn and that they were lost in Köppen Hill. Some be-
eve that the Piper was an agent of the bishop of
lmütz, who in the late 1200's drew many Hamelin lads
Moravia, where they settled. Others claim robbers
dnapped the children. It is also possible that the
gend came from the Children's Crusade of 1212.

James F. Poag

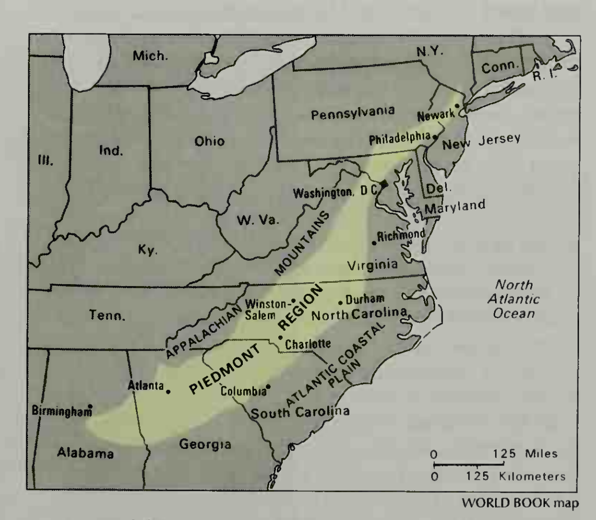
iedmont, *PEED mahnt,* is a territorial region in north-
estern Italy. It includes the upper valley of the Po River.
or location, see **Italy** (political map). The name *Pied-
ront* means *foot of the mountain.* It refers to the re-
ion's position at the base of the Alps. The region in-
udes the provinces of Alessandria, Asti, Cuneo,
ovara, Torino, and Vercelli and has about 4 $\frac{1}{4}$ million
eople. Turin is the capital and industrial center. Farm-
g is the chief economic activity in this fertile region. It
as once part of the Sardinian kingdom (see **Sardinia,
ingdom of**). Piedmont was the center of Italian national-
m in the 1800's, and its ruler, Victor Emmanuel II, be-
ıme the first king of Italy in 1861. David I. Kertzer

iedmont Region, *PEED mahnt,* is an area of gently
lling to hilly land lying between the Appalachian
ountains and the Atlantic Coastal Plain of the United
ates. It is sometimes called the Piedmont Plateau. It
as named for the Piedmont region in Italy. It varies in
idth from about 50 miles (80 kilometers) in the north to
ore than 125 miles (201 kilometers) in the south.

The division between the Piedmont Region and the
oastal Plain is marked by the Fall Line for the rivers
owing toward the Atlantic Ocean. Along this line,
reams from the west drop from the harder, rocky
ound near the mountains to the softer Coastal Plain.

Many large cities have developed along the Fall Line,
artly because of the access to water power and tidewa-
r. They include Newark, New Jersey; Philadelphia;
ashington, D.C.; Richmond, Virginia; and Columbia,
outh Carolina.

The Piedmont Region covers about 80,000 square
iles (207,000 square kilometers). It ranges in elevation
from 300 feet (91 meters) above sea level on the east to
1,200 feet (366 meters) on the west.



Tobacco is widely grown in the Piedmont Region. The
Piedmont cities of Winston-Salem, North Carolina, and
Richmond, Virginia, account for about half of the total
production of cigarettes in the United States. The Pied-
mont section of Virginia and Pennsylvania is fine apple-
growing country. The dairy industry is important in the
northern Piedmont. Furniture manufacturing is a major
industry in the central Piedmont. The southern Piedmont
is the leading U.S. cotton-textile producing area.

Pier has several meanings. Two kinds of piers are used
in building construction. One kind is a block of concrete
or masonry that forms part of a building's foundation.
The other kind of pier supports a bridge and may be
made of concrete, steel, or timber. In architecture, sup-
porting pillars for arches or masonry walls are some-
times called piers. A pier may also be a platform that ex-
tends into a body of water for loading and unloading
ships. See also **Bridge; Building construction** (Founda-
tions); **Cofferdam.** William E. Saul

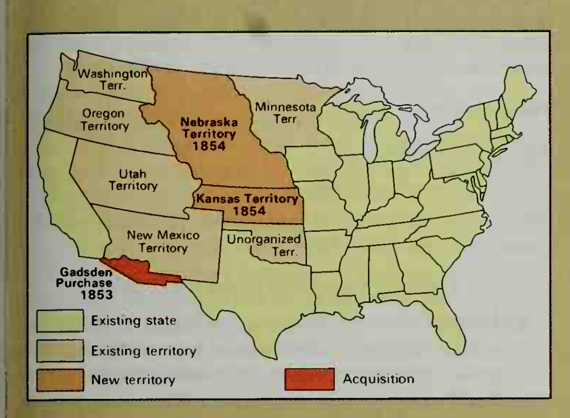
Pierce, Franklin (1804-1869), served as President during a period of increasing bitterness between North and South that later led to the Civil War. He won the Democratic nomination for President in 1852 after the four strongest candidates had fought to a stalemate. Pierce gained support because he strongly favored the Compromise of 1850, which sought to settle the slavery dispute. "If the compromise measures are not . . . firmly maintained," he said, "the Constitution will be trampled in the dust." At 48, Pierce became the youngest President of the United States up to that time.

The personal good looks of Pierce and his brilliant speaking manner impressed all who met him. People in New Hampshire respected his service as a U.S. representative and senator, and as a brigadier general in the Mexican War. But few people outside his home state had heard of Pierce until he ran for President.

As President, Pierce faced two difficult problems: (1) growing Northern opposition to any expansion of slavery, and (2) rising prejudice against immigrants. He angered Northerners by supporting the Kansas-Nebraska Act, which made slavery possible in a large area of the West. This act provided the issue that created the Republican Party. Pierce stirred up further opposition when he protected the rights of immigrants. Those opposed to granting rights to immigrants also formed a new party, called the Know-Nothing, or American, Party. By the time Pierce's term ended, the Democratic Party had lost much of its strength. Few Democrats favored Pierce for reelection.

Pierce's Administration marked one of the most prosperous periods in American history. The California gold rush still attracted people westward. Federal grants of land spurred railroads to extend their lines westward. And the Gadsden Purchase added land from Mexico to the Territory of New Mexico. The literary world discussed such new works as Henry David Thoreau's *Walden,* Henry Wadsworth Longfellow's *The Song of Hiawatha,* and Walt Whitman's *Leaves of Grass.* People hummed Stephen Foster's "My Old Kentucky Home, Good Night." At Christmastime in 1855, carolers sang "Hark! The Herald Angels Sing" for the first time.

Early life



Franklin Pierce was born in Hillsboro, N.H., on Nov. 23, 1804. His father, Benjamin Pierce, had served in the Revolutionary War, and later became a brigadier general in the state militia. The elder Pierce served two terms as governor of New Hampshire. Franklin spent a happy childhood with his six older and two younger brothers and sisters.

At the age of 11, the boy was sent to the academy in nearby Hancock. Friends recalled that just after Franklin entered the school, he became homesick and returned home on foot. His father put him into a wagon, drove him halfway back to the academy, and left him at the roadside, never saying a word. The boy trudged the remaining 7 miles (11 kilometers) back to school. A year later, he transferred to the academy at Francestown, N.H., and later to Phillips Exeter Academy. In 1820, he entered Bowdoin College, where he became a close friend of classmate Nathaniel Hawthorne.

Pierce spent much of his college life in social activities. He joined literary and political clubs and became active in debating groups. At the end of his second year Pierce's marks were the lowest in his class. He then settled down to study. Pierce ranked third in his class when he graduated in 1824.

Political and public career

Pierce began studying law under Governor Levi Woodbury of New Hampshire. He later studied under Judge Samuel Howe and Judge Edmund Parker. In 1827, Pierce opened his own law office in Concord, N.H.

The Gadsden Purchase from Mexico in 1853 added new territory to the United States. Congress organized the Nebraska and Kansas territories in 1854.

The world of President Pierce

Japan emerged from world isolation after Commodore Matthew Perry of the United States Navy sailed to Tokyo Bay in 1853 and 1854. He negotiated a treaty that gave the United States trading rights at two Japanese ports.

The English explorer David Livingstone became the first European to cross the interior of Africa during an expedition that lasted from 1853 to 1856.

The Crimean War was fought from 1853 to 1856 between Russia and the allied forces of France, Britain, Turkey, and Sardinia. It ended in a Russian defeat.

Florence Nightingale of England took charge of a hospital in Turkey during the Crimean War and established new standards of nursing care and hospital administration. Her efforts saved countless lives and brought her international acclaim.

The Republican Party was established in 1854 by antislavery groups who opposed the Kansas-Nebraska Act. The act allowed citizens of the Kansas and Nebraska territories to decide for themselves whether to permit slavery.

Frederick Douglass, a runaway slave who became the leading spokesman for black rights in the 1800's, published an autobiography, *My Bondage, My Freedom,* in 1855.

The Bessemer steel process was invented by Sir Henry Bessemer of England in 1856. It was the first process that enabled large quantities of steel to be made inexpensively.

WORLD BOOK map

Entry into politics. Pierce supported Andrew Jackson's campaign for the presidency. In 1829, he won election to the New Hampshire House of Representatives. He was reelected two years later and became Speaker of the House. In 1833, Pierce won a seat in the United States House of Representatives. After serving two terms he was elected to the United States Senate. At 32, he became the youngest senator.

Pierce's family. Pierce's years in Congress were not happy. In 1834, he had married Jane Means Appleton (March 12, 1806-Dec. 2, 1863), whose father had been a Congregational minister and president of Bowdoin College. Mrs. Pierce suffered from tuberculosis. She disliked Washington and rarely went there. Pierce finally agreed to her wishes to come home and resigned from the Senate in 1842, shortly before his term ended. Mrs. Pierce's natural shyness deepened to melancholy after two of their three sons died in early childhood.

Soldier. Soon after the Mexican War began in 1846, President James K. Polk commissioned Pierce a colonel in the U.S. Army. A few months later, Pierce was promoted to brigadier general. He served under General Winfield Scott on the expedition to Mexico City. Pierce

Important dates in Pierce's life

1804 (Nov. 23) Born in Hillsboro, New Hampshire.
1833 Elected to the U.S. House of Representatives.
1834 (Nov. 10) Married Jane Means Appleton.
1836 Elected to the United States Senate.
1847 Served as brigadier general in the Mexican War.
1852 Elected President of the United States.
1869 (Oct. 8) Died in Concord, New Hampshire.

New Hampshire Department of Resources and Economic Development

Franklin Pierce was born in Hillsboro, New Hampshire, in a house that no longer exists. The Pierce family moved into the spacious Hillsboro house shown here when Franklin was 3 weeks old.

The Pierce Brigade, Concord, N.H.

Jane Pierce is shown above with the Pierces' son Benny, who died in an accident just before his father became President.

commanded a brigade in the attack on Churubusco and suffered a leg injury when thrown from his horse. He returned to the assault the next day. When close to the enemy lines, he wrenched his injured leg, fainted from pain, and lay helpless under fire until the end of the battle. Political enemies later accused him of cowardice.

Election of 1852. Pierce resumed his law practice in Concord after the war. He had become one of New Hampshire's leading Democrats by the time his party's national convention met in 1852. The delegates faced a difficult job in choosing a candidate for President who would be acceptable to all factions of the party. The four strongest candidates were Senator Stephen A. Douglas of Illinois and three former Cabinet members—James Buchanan, William L. Marcy, and Lewis Cass.

After 34 ballots, it began to appear that none of the favored candidates could win the nomination. Delegates from Virginia then nominated Pierce. The New Englander expected some Northern support, and the South trusted him because he had supported the Compromise of 1850 and endorsed strict enforcement of the Fugitive Slave Law. As the balloting continued, several Buchanan delegations swung to Pierce, and he won on the 49th ballot. The convention chose Senator William R. D. King of Alabama for Vice President.

The Whigs nominated General Winfield Scott for President and Secretary of the Navy William A. Graham for Vice President. The Compromise of 1850 had temporarily settled the slavery problem, and no real issues appeared to separate the two parties (see **Compromise of 1850**). But the campaign disclosed that Scott really opposed slavery, causing opposition to him in the South.

Pierce's election

Place of nominating convention	Baltimore
Ballot on which nominated	49th
Whig opponent	Winfield Scott
Electoral vote*	254 (Pierce) to 42 (Scott)
Popular vote	1,607,510 (Pierce) to 1,386,942 (Scott)
Age at inauguration	48

*For votes by states, see **Electoral College** (table).

Pierce won a majority of the popular vote and carried many more states than did Scott.

Pierce's Administration (1853-1857)

Cabinet. Pierce tried to promote harmony in the Democratic Party by choosing men from all factions for his Cabinet. His appointments consisted of two conservative Southerners (Guthrie and Dobbin), two conservative Northerners (Marcy and Campbell), an antislavery Northerner (McClelland), a states' rights Southerner (Davis), and a New England Whig (Cushing). Vice President King, who had been ill for several months, died in April 1853 without ever performing the duties of his office (see **King, William R. D.**).

Life in the White House began in an atmosphere of tragedy and grief for the Pierces. They had seen their 11-year-old son Benjamin die in a railroad accident just two months before the inauguration. Mrs. Pierce collapsed from grief and did not attend her husband's inauguration. She secluded herself in an upstairs bedroom for nearly half of his term. Washington gossips called her "the shadow in the White House."

Mrs. Abby Kent Means, an aunt of Mrs. Pierce, served as White House hostess during Pierce's first two years in office. Mrs. Pierce finally appeared at a White House function on Jan. 1, 1855, and thereafter attended state dinners frequently. But one visitor remarked that she remained the "very picture of melancholy."

The Kansas-Nebraska Act. In January 1854, Senator Douglas introduced a bill that he hoped would hasten frontier settlement. It proposed to carve two new territories, Kansas and Nebraska, out of the Indian lands in the West. The bill provided that settlers in the new territories would decide for themselves whether to permit slavery. Douglas' bill threatened to upset the uneasy slavery truce established by the compromises of 1820 and 1850. A farsighted statesman would have seen the danger in such a law. But Pierce, acting on the advice of his party leaders, supported the bill. It became law on May 30, 1854 (see **Kansas-Nebraska Act**). Both slavery and antislavery people poured into Kansas. Each group sought to control the territory. Their rivalry soon developed into armed clashes (see **Kansas** ["Bleeding Kansas"]).

Vice President and Cabinet

Vice President	*William R. D. King
Secretary of state	William L. Marcy
Secretary of the treasury	James Guthrie
Secretary of war	*Jefferson Davis
Attorney general	Caleb Cushing
Postmaster general	James Campbell
Secretary of the Navy	James C. Dobbin
Secretary of the interior	Robert McClelland

*Has a separate biography in *World Book*

The Kansas-Nebraska Act created a violent realign-
ıent of political parties. The Democrats defended the
xisting laws on slavery. The Whigs, already weakened
y sectionalism, disintegrated. This hastened the birth of
ıe new Republican Party and the Know-Nothing Party
ee **Know-Nothings; Republican Party**).

Foreign affairs. In his inaugural address, Pierce had
oldly summarized his attitude toward foreign policy by
ıying: "My administration will not be controlled by any
mid forebodings of evil from expansion." In 1853, he
dvocated annexing Hawaii. This plan fell through, partly
ecause King Kamehameha died. The Gadsden Purchase
f 1853 gave the country a southern railroad route to the
acific Coast and settled the boundary question with
Mexico (see **Gadsden Purchase**). At Pierce's insistence,
ıe Senate ratified a trade treaty with Japan in 1854,
pening Japan to American trading interests.

Acts of this kind fitted well with the attitude of Ameri-
ans, who believed in national expansion. But when
ıree of Pierce's diplomats claimed in 1854 that the Unit-
d States had the right to seize Cuba from Spain, the
ublic reacted against Pierce. See **Ostend Manifesto**.

Later years

Pierce's handling of the slavery issue destroyed his
olitical usefulness. After the inauguration of James
uchanan, Pierce and his wife went abroad in a futile at-
empt to improve her health. The Pierces spent two
ears on the island of Madeira, visited Europe, and then
eturned home. Mrs. Pierce died on Dec. 2, 1863.

Pierce became a bitter critic of President Abraham
incoln during the American Civil War. He charged that
incoln could have avoided the conflict by proper lead-
rship. Pierce died on Oct. 8, 1869, and was buried in
ıe Old North Cemetery at Concord. Philip S. Klein

lichols, Roy F. *Franklin Pierce.* Rev. ed. 1969. Reprint. Am. Political Biography Pr., 1993.

Pierce, Samuel Riley, Jr. (1922-2000), served as sec-
etary of the Department of Housing and Urban Devel-
pment (HUD) from 1981 to 1989. He became the first
lack to serve in President Ronald Reagan's Cabinet.

In 1989, the U.S. Congress investigated Pierce on charges of mismanagement and abuse of resources and funds as secretary of HUD. The investigators concluded that, under Pierce, HUD had become a center of influence peddling and favoritism toward Pierce's friends and political allies. In the early 1990's, several of Pierce's aides were found guilty or pleaded guilty to charges related to influence peddling and favoritism. In 1995, prosecutors announced that Pierce would not be charged.

Pierce was born in Glen Cove, New York. He graduated from Cornell University in 1947 and received a law degree from Cornell Law School in 1949. He earned a Master of Laws degree from New York University School of Law in 1952. From 1953 to 1955, he was an assistant United States attorney in New York. In 1955, he became an assistant to the undersecretary of labor. Pierce served as a New York state judge in 1959 and 1960 and as general counsel for the Department of the Treasury from 1970 to 1973. Lee Thornton

Piero della Francesca, *PYAIR oh DEHL uh fran CHEHS kuh* (1420?-1492), was an Italian Renaissance painter. Piero favored calm, restrained figures in clear, simple spaces. His works combine precise contours and carefully created illumination with sensitive color and harmonious design. In the *Baptism of Christ,* he painted early morning light over a quiet landscape to set a gentle, dreamlike mood. This painting is reproduced in the **Jesus Christ** article. Piero's most famous work is the series called *The Legend of the True Cross,* painted in *fresco,* which means it was painted on damp plaster. In one episode, *The Dream of Constantine,* Piero used bright artificial light and deep shadow for dramatic effect.

Piero was born in Sansepolcro, Italy, near Arezzo. In Florence, Piero learned to paint in the new Renaissance style of the artists Masaccio, Fra Angelico, and Domenico Veneziano. He also learned the construction of perspective, which fascinated him. From Domenico Veneziano in particular, Piero acquired skill in the treatment of light and delicate color. David Summers

Pierpont, Francis Harrison (1814-1899), was governor of the "Restored Government of Virginia" during the American Civil War. *Restored Government of Virginia* was the name given to some northern counties of Confederate Virginia that Union forces had occupied.

Pierpont was born near Morgantown, Virginia (now in West Virginia). His family name has also been spelled *Pierpoint.* He became a lawyer, joined the Whig Party, and strongly opposed slavery. In 1861, Virginia *seceded* (withdrew) from the Union. Pierpont then led a movement in western Virginia to establish a state government loyal to the Union. A convention of western Virginians declared all state offices vacant and chose Pierpont as provisional governor. He set up a loyal legislature of members from western Virginia. The convention wrote a new state constitution and, in 1863, Congress approved West Virginia's admission to the Union. The new state chose Arthur I. Boreman as its first governor, and Pierpont became head of the Restored Government of Virginia. President Abraham Lincoln considered him to be governor of Virginia for the rest of the war. After the Confederacy surrendered in 1865, Pierpont moved to Richmond and continued as governor under federal military authority until 1868. James E. Sefton

Pierpont Morgan Library is a museum and center for scholarly research in New York City. The museum ranks among the world's greatest treasuries of artistic, historical, literary, and musical works. The collection consists of rare books and manuscripts, prints and drawings, paintings, and other art objects. It concentrates on the art, history, and literature of Western civilization from the Middle Ages to the 1900's.

The museum is located in a complex of buildings between Madison and Fifth avenues on 36th Street. The complex includes the former town house of American banker John Pierpont Morgan, Jr. It also includes the library commissioned by Pierpont Morgan, Sr., and designed by the firm of McKim, Mead & White and completed in 1906. John Pierpont Morgan, Jr., founded the institution in 1924. The two Morgans assembled much of the museum collection, which continues to be enlarged. Critically reviewed by the Pierpont Morgan Library

Pierre, *peer* (pop. 13,876), is the capital of South Dakota. It also serves as the chief trading center of a large agricultural region. Pierre lies on the east bank of the Missouri River, near the center of South Dakota (see **South Dakota** [political map]).

The State Capitol, completed in 1910, has a central rotunda, flanked by legislative wings. Many of Pierre's residents work in the city's state and federal government offices. The livestock industry is also a major employer.

Pierre was named for Pierre Chouteau, an early fur trader. The first permanent settlers arrived in 1878. The Chicago and North Western Railway reached the settlement in 1880. The town prospered as the railroad terminus. This portion of the Chicago and North Western is now the Dakota, Minnesota and Eastern Railroad. Pierre became the state capital in 1889, shortly after South Dakota was made a state.

Pierre is the seat of Hughes County. It has a mayor-council form of government. Edward Patrick Hogan, Sr.

Pietà. See **Michelangelo.**

Pietermaritzburg, *PEE tuhr MAR ihts burg* (pop. 156,473; met. area pop. 211,473), is the capital and a major trading center of the province of KwaZulu-Natal in South Africa. For location, see **South Africa** (political map). The city's factories produce aluminum, rubber, and furniture. Pietermaritzburg has a university, a teac ers college, and many parks and gardens. *Boers* (peo of Dutch, German, or French ancestry) founded the ci in 1838. Today, many people in Pietermaritzburg are d scendants of immigrants from what are now India an Pakistan. The city's largest population group consists Zulus, a black ethnic group. Bruce Fetter

Piezoelectricity, *pee AY zoh ih LEHK TRIHS uh tee,* i an electric phenomenon that occurs in certain nonmetallic minerals, such as quartz, Rochelle salt, and to maline. These crystals develop an electric charge on their surfaces when they are stretched or compresse along an axis. In addition, voltage applied to such crys tals causes them to expand and contract, producing vi brations. Crystals that have these properties are called *piezoelectric crystals.* Pierre and Jacques Curie, two French physicists, published their discovery of piezoelectricity in 1880.

Piezoelectricity has many uses. Piezoelectric crystals control the frequency of electric current in radio trans mitters. The crystals are cut so that only signals of a ce tain frequency can pass through them. Piezoelectric crystals in a phonograph pickup cartridge convert the vibrations of the phonograph needle into a varying ele tric signal. Piezoelectric crystals are also used in micro phones and other electronic devices that change soun waves into electric signals. Thomas T. Liao

Pig iron. See **Iron and steel** (Pig iron).

Pigeon is any of the larger members of the pigeon a dove family. The smaller members are usually called *doves.* In this article, the term *pigeon* refers to both pigeons and doves.

There are about 300 species of pigeons. They live in all parts of the world except the Arctic, Antarctic, and some oceanic islands. Most species live in tropical climates. For example, 24 species of pigeons make their home in Mexico. Only 11 species live in the United States, and only 3 species are found in Canada.

The body of a pigeon

Pigeons have a plump body, a small head, and short sturdy legs. They are swift, powerful fliers. The large

G. Ronald Austing

Pigeons are common in mo large cities. They usually bui their nests of loose-fitting sticks. The male, *right,* and fe male, *left,* both help raise th young, which are called *squabs.*

light muscles in a pigeon's chest may be two-fifths of he bird's total body weight. The feathers of pigeons are tiffer and smoother than those of most other birds. heir texture smooths the flow of air around the pi- jeon's body during flight. Some kinds of pigeons have pecially shaped feathers that may help them fly at peeds slower than normal. The feathers of other spe- ies produce sounds during flight. These pigeons com- nunicate with one another by means of these sounds.

Most species of pigeons measure from 10 to 15 nches (25 to 38 centimeters) long. One of the smallest pecies, the *common ground-dove,* grows about 6 nches (15 centimeters) long and weighs about 1 ounce 28 grams). The largest species, the *Victoria crowned-)igeon,* is almost 3 feet (91 centimeters) long and veighs from 2 to 3 pounds (0.9 to 1.4 kilograms).

Most pigeons have dull-colored feathers that are)lack, blue, brown, or gray. The males and females of nost species look much alike, but the males are a little arger and brighter. Some species, such as the *Asian ruit-pigeon* and the *bleeding-heart pigeon,* rank among he most beautiful birds in the world. These birds have)right markings on the front parts of the body. A pigeon nay use its markings to attract a mate or to threaten)ther pigeons of the same species that approach its nest)r territory.

Pigeons drink in an unusual way. They do not tip their head up with each sip, as most birds do. Pigeons thrust their beak into the water and suck the liquid through it as though it were a straw.

The life of a pigeon

Most pigeons build their nests in trees. But one species, the *rock pigeon,* nests on rocky cliffs or on the lower ledges and sills of buildings. Other species, called *ground-doves,* build their nests on the ground.

Pigeons begin to look for food and water early in the morning. They generally rest during part of the afternoon and then seek more food and water. The birds return to their roost before nightfall.

Most species of pigeons live in the same region throughout the year. However, many species that live in cool regions migrate in large flocks during the fall and spring. People often hunt pigeons during these migrations.

Food. Pigeons eat fruits, grains, and nuts, and they sometimes feed on insects, snails, and worms. Most pigeons also eat grit and minerals such as salt. Some species obtain food by pecking at the ground. Others do not usually land on the ground and so feed in trees.

Flocks. When not breeding, most species of pigeons live in flocks. These flocks may consist of more than one

The homing pigeon is often used for racing and carrying messages. This bird is noted for being able to find its way home from great distances.

species. The large number of birds in a flock increases the chances of finding food. Flocks also provide protection against such enemies as cats, hawks, martens, owls, and rats. Some pigeon flocks include other species of birds, such as blackbirds and sparrows. The presence of these birds further improves the chances of locating food and of being warned of danger.

Life history. Male and female pigeons pair for the breeding season and may remain paired for life. Most other kinds of birds pair for a single nesting cycle or a single season. During courtship, the male pigeon bows and coos to the female while the female watches him. The two birds groom each other's feathers, and the male feeds the female a few seeds. The courtship lasts a few days, after which mating occurs.

Pigeons build a shallow, but often strongly interwoven nest of twigs and grass. In most species, the female lays two white eggs. The parents take turns sitting on the eggs, which hatch in about 17 days. The young, called *squabs,* are blind and almost featherless. They grow rapidly. Some of the smaller species can fly before they are two weeks old.

Both parents feed the newly hatched young a white liquid called *crop milk.* The milk, which is similar to the milk of mammals, is produced in the *crop,* a sac in the base of the neck of the parents. The parents pump the milk down the throat of the squabs. The young begin to eat solid food after about 10 days.

Most pigeons that survive the first few months live from three to five years. The larger species live longer than the smaller ones.

Kinds of pigeons

There are two main groups of pigeons, wild and domestic. Domestic pigeons are bred by people.

Wild pigeons. Of the nearly 300 wild species, some of the best known are the Victoria crowned-pigeon, the fruit-pigeon, the bleeding-heart pigeon, the rock pigeon, the band-tailed pigeon, and the mourning dove.

Victoria crowned-pigeons, the largest of all pigeons, live in New Guinea. They have a variety of colors, and tufts of thin, lacy feathers form a crest on their head. The brightly colored fruit-pigeon is found in Asia and on islands in the South Pacific Ocean. Its nest is so flimsy that the female must hold her eggs and the nest in place if even a slight wind blows. The bleeding-heart pigeon of the Philippines has white underparts except for a bright red spot on its chest.

The rock pigeon nests on cliffs in Africa, Asia, and Europe. It is dark blue and has two black stripes on its wings, a white rump, and a black band on its tail. The feathers on its neck are glossy green and purple. The band-tailed pigeon, a favorite game bird that makes its home in the western part of the United States, has a black band across its tail. Hunters shoot thousands of these pigeons every fall for food and sport.

The mourning dove is the most common of the smaller North American wild pigeons. It makes a sad, cooing sound and is well known as both a game bird and songbird. Conservationists try to control the number of mourning doves killed by hunters. Another game bird, the *passenger pigeon,* was hunted to extinction in the 1800's and early 1900's. The last passenger pigeon died in the Cincinnati Zoo in 1914.

Domestic pigeons. Scientists believe that most breeds of domestic pigeons are the descendants of wi rock pigeons. Many of these birds differ greatly from their wild ancestors. But if a domestic pigeon become wild, its descendants resemble their wild ancestors aft several generations. For example, city pigeons, which are wild descendants of a number of domestic breeds, resemble wild rock pigeons.

Rock pigeons were domesticated in Egypt about 31 B.C. Through the centuries, breeders have developed over 150 types of pigeons for various purposes. Pigeon have been bred to serve as a source of food, to carry messages, or for racing, recreation, or show.

Popular types of pigeons raised for food include the *carneaux pigeon,* the *dragoon pigeon,* the *white malte pigeon,* and the *white king pigeon.* These birds produc large squabs that many people consider a delicacy.

People use *homing pigeons,* also called *homers,* to carry messages and for racing. These pigeons have a re markable ability to find their home loft from great distances. *Carrier pigeons* are also used to carry message These large, swift birds have fleshy growths of skin called *wattles* around their beak and eyes.

Pigeon shows feature specially bred varieties of pigeons. Birds displayed in such shows include the *fantai pigeon,* the *pouter pigeon,* and the *Jacobin pigeon.*

Other domestic breeds include the *tumbler pigeon* and the *roller pigeon,* both of which perform acrobatic in the air. One domestic type, the *ringed turtle dove,* ha unknown ancestors.

Pigeons and human beings

People hunt pigeons for both food and sport. They also use these birds for scientific research. For example scientists study ringed turtle doves to better understand how hormones control behavior. Scientists also study homing pigeons in an effort to learn how birds are able to find their way when flying great distances.

Some kinds of pigeons eat large amounts of grain raised by farmers. But other species eat the seeds of var ious harmful weeds. Several species of pigeon depend directly on people. Since 1930, for example, the *collared dove* has spread throughout Europe by relying on crops for food and buildings for shelter.

Pigeons that live in cities can be a great nuisance to people. The droppings of large numbers of pigeons are expensive to clean up and may help erode stone and marble. The droppings may also stop up the roof drains of buildings. The birds also can spread such diseases as histoplasmosis and psittacosis, which affect the lungs and other organs of human beings (see **Histoplasmosis; Psittacosis**).

Scientific classification. Pigeons and doves make up the family Columbidae in the order Columbiformes. The scientific name for the common ground-dove is *Columbina passerina.* The bleeding-heart pigeon is *Gallicolumba luzonica.* The Victoria crowned-pigeon is *Goura victoria.* The rock pigeon is *Columba livia,* and the band-tailed pigeon is *C. fasciata.* The mourning dove is *Zenaida macroura.* The ringed turtle dove is *Streptopelia risoria.* Edward H. Burtt, Jr.

The northern pike is a large freshwater fish that is popular as a fighting game fish and also as a delicious food fish.

Pike is the common name of a family of freshwater fish noted for their greedy appetite and fighting quality. Members of the pike family have long, slender bodies and a duckbill-shaped snout filled with many teeth. Two members of the pike family are called *pickerel:* the *bull-
dog pickerel,* also called the *redfin pickerel,* the *mud pickerel,* or the *grass pickerel;* and the *chain pickerel.* The three forms of muskellunge also are in the pike fam-
ily. The so-called *pike perch,* more accurately called *walleye,* is a perch. The *gar pike* (garfish) is a gar. See **Muskellunge; Pickerel.**

The *northern pike* and the muskellunge are the most important members of the family. They are often dis-
played as trophy fish. The northern pike lives in the northern fresh waters of Europe and Asia, and in the Great Lakes and smaller lakes in Canada and the upper Mississippi Valley of North America. The northern pike may grow to be 4 feet (1.2 meters) long and weigh more than 40 pounds (18 kilograms). It commonly weighs from 2 to 10 pounds (0.9 to 4.5 kilograms). It is bluish- or greenish-gray, with irregular rows of whitish or yellow-
ish spots. The northern pike is a fine game fish. Its flesh is good to eat.

Scientific classification. The northern pike belongs to the pike family, Esocidae. Its scientific name is *Esox lucius.*

Robert D. Hoyt

Pike, James Albert (1913-1969), was a controversial American clergyman. He became an Episcopal bishop—reaching a peak of his profession—and then began to question some of the basic teachings of his church.

Pike was born in Oklahoma City. He was raised a Roman Catholic but drifted away from formal religion. In 1944, Pike joined the Episcopal Church. He was or-
dained a priest in 1946, and in 1952 he became dean of the Cathedral of St. John the Divine in New York City. There, Pike gained a national reputation as a theologian and preacher with his vigorous support of the church and attacks on social injustice. In 1958, he was elected bishop of the Episcopal Diocese of California.

In 1960, Pike publicly expressed discontent with sev-
eral Episcopal doctrines, including those on the Trinity and the virgin birth. He resigned as bishop in 1966 and in 1969 announced that he was leaving the church. Pike said he still believed in God, Christ's Resurrection, and life after death. However, Pike's religious practice during this period included mysticism and attempts to commu-
nicate with the dead as well as traditional Christian ele-
ments. In 1969, Pike went to Israel to investigate the ori-
gins of Christianity. He died there, in the Judean desert.

Charles H. Lippy

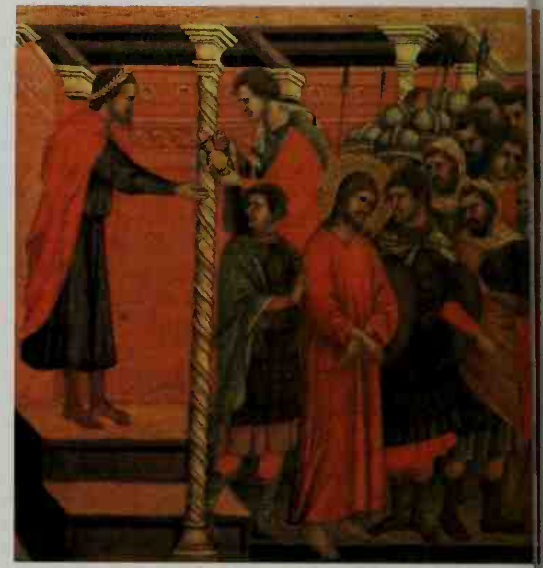
Pike, Zebulon Montgomery, *ZEHB yu luhn* (1779-1813), an American general and explorer, won fame for his discovery of Pikes Peak, a mountain in the Colorado Rockies, in 1806. Pike's first important mission was to explore the upper Mississippi River in 1805.

In 1806 and 1807, Pike explored the southwestern United States. While following the Arkansas River, he sighted the peak that now bears his name from at least 150 miles (241 kilometers) away. He later turned south to find the source of the Red River but instead followed the Rio Grande into Spanish territory. Spanish troops met Pike and took him and his men as captives to Santa Fe (now in New Mexico). They were released months later.

Pike returned from his trip with valuable information about the area for the U.S. government. He was ordered on this mission by General James Wilkinson, who may have been plotting an illegal invasion of Spanish territory in the area with American statesman Aaron Burr. Some historians believe Pike was spying for Wilkinson.

Pike was born in Lamberton (now a part of Trenton), New Jersey, on Jan. 5, 1779. He began his military career at the age of 15. In the War of 1812 (1812-1815), he led a successful advance on York (Toronto), Canada, in which he lost his life. Dan L. Flores

Pikes Peak is probably the best known of the Rocky Mountain peaks in Colorado. It is the first one seen as travelers approach from the east. It lifts its snow-capped peak 14,110 feet (4,301 meters) above sea level, in the Front Range (see **Colorado** [physical map]). Pine and spruce forests grow to a height of 11,700 feet (3,566 meters) on its slopes.



The mountain was named for Lieutenant Zebulon Montgomery Pike. In November 1806, Pike climbed partway up the mountain, but lack of supplies forced him to turn back. Major Stephen Harriman Long led an exploring party to the top in 1820.

Today, the top of Pikes Peak can be reached on horseback or by a 9-mile (14-kilometer) cog railway. A 30-mile (48-kilometer) automobile highway leads to the top from Colorado Springs, 12 miles (19 kilometers) to the east. The famous Pikes Peak Auto Race is held there every summer. A huge searchlight was installed on top of the mountain in 1905. The National Weather Service maintains one of the highest meteorological stations in the world on Pikes Peak. Pikes Peak is the center of one of the most popular mountain-resort areas in America. Denver is located 65 miles (105 kilometers) north of the peak. John L. Dietz

Pilate, *PY luht,* **Pontius,** *PAHN shus,* was a Roman governor of Judea from A.D. 26 to 36, at the time of the Crucifixion of Jesus Christ. Information about Pilate comes from two sources, the New Testament and Jewish writers from Pilate's time to about A.D. 100. The New Testament portrays him as generally weak and poor at making decisions, while the Jewish sources depict him as a strong figure of authority. Both sources report that he was unjustly hostile toward the Jews. His name was found in 1961 inscribed on a stone slab near Caesarea in modern Israel.

All four Gospels indicate that Jewish authorities manipulated Pilate in their desire to have Jesus crucified. Matthew is the only Gospel to report the famous scene

Detail of *The Maestà* (1308-1311), a tempera altarpiece on wood panel by Ducc[io di] Buoninsegna; Museo dell'Opera Metropolitana, Siena, Italy (SCALA/Art Resou[rce])

Pilate washed his hands to symbolize his refusal to accept re-sponsibility for the Crucifixion of Jesus.

of Pilate's washing his hands, saying: "I am innocent of the blood of this just person: see ye to it" (Matthew 27:24). The Gospel of Luke says that Pilate found out tha[t] Jesus was from Galilee and sent Him to Herod Antipas, the governor of Galilee, who was staying in Jerusalem [at] the time. Pilate apparently wanted to avoid having to make a decision about Jesus's fate. At one point in the trial, Pilate offered to release Jesus, probably because [he] was not convinced of Jesus's guilt.

Some traditions claim that Pilate died in A.D. 39 on th[e] orders of the Roman emperor Caligula, either by committing suicide or by execution. According to another tradition, he and his wife, Procla, became converts to Christianity. Procla is considered a saint in the Greek O[r]thodox Church, and both she and Pilate are saints in th[e] Ethiopian Orthodox Church. Richard A. Edwards

Pile is a column used to support buildings, bridges, and other structures. Piles are often used to prevent buildings from sinking or collapsing. When the top layers of soil are too soft to support the foundation, piles are used to transfer the weight of the structure to a firmer layer of soil or rock. For some skyscrapers, piles may reach 200 feet (60 meters) below the surface. Piles may also be used to raise a structure above water or to support wharves. Piles may be made of wood, steel, or concrete. They are usually driven into the ground by a *pile driver,* a kind of hammer that drives the pile into po-sition by means of vibration and a weight. Piles also ma[y] be drilled into position or placed into predrilled holes. William E. Saul

The Mayflower in Plymouth Harbor, an 1882 oil painting by William F. Halsall; Pilgrim Society, Plymouth, Mass.

The ***Mayflower*** brought the first Pilgrims from England to what is now Massachusetts, where they founded Plymouth Colony. The ship reached Plymouth Bay, *above,* on Dec. 26, 1620.

Pilgrims were the early English settlers of New England. The first group landed at what is now Plymouth, Mass., in 1620. The Pilgrims established Plymouth Colony along Cape Cod Bay.

The early Pilgrims included many *Separatists.* These people once belonged to the body of English Protestants known as *Puritans.* The Puritans wished to adopt reforms that would purify the Church of England, the nation's official church. The Separatists decided that they could not reform the church from within. They separated from the church and set up their own congregations.

In 1606, William Brewster helped form a small Separatist congregation in Scrooby, England. Separatist

Pilgrims Going to Church, oil on canvas, New-York Historical Society, New York City, Robert L. Stuart Collection

The Pilgrims walked to church in groups for protection. Most of the men carried muskets to guard against attacks by Indians. A preacher with his Bible is near the center of the above picture, painted in 1867 by the American artist George H. Boughton.

groups were illegal in England, and in 1607 the Scrooby congregation tried to flee to Amsterdam, Holland, to avoid arrest. They were caught, but most of them left England the next year. In 1609, the congregation settled in the Dutch town of Leiden.

After several years in Holland, some Separatists began to fear that their children would be more Dutch than English. As foreigners, they could not buy land or work in skilled trades. In addition, war had begun in Europe. The new land of America appealed to them. They offered to establish an English colony in America and found a group of English merchants willing to finance their expedition. In September 1620, 41 members of the Leiden congregation sailed for America on the ship *Mayflower,* along with 61 other English people. The group reached what is now Provincetown Harbor on Nov. 21, 1620. They explored the nearby coast and soon chose Plymouth as the site of their colony.

The term *Pilgrim* may have come from William Bradford, the second governor of Plymouth Colony. Bradford wrote that "they knew they were pilgrims" when they left Holland. However, for 200 years these people were known as "Founders" or "Forefathers," rather than "Pilgrims." Joan R. Gundersen

Pillory, *PIHL uhr ee,* was an instrument once used to punish people for minor offenses. It was a wooden framework with holes cut in it for the arms and head of the victims. They were locked into these holes for a certain length of time. The pillory stood in the public square. Prisoners suffered both because of their uncomfortable position and because passers-by jeered and often threw stones and rotten eggs at them. Often the prisoners' heads were shaved to increase their shame and embarrassment.

The English government used the pillory in the 1600's to punish certain writers and publishers. Daniel Defoe was subjected to the pillory for publishing a libelous essay. The Puritans brought the pillory with them to New England and used it to punish "notorious drunkards, scolds, and bawds." Marvin E. Wolfgang

Pilot International is a service organization of business and professional leaders. The organization has about 19,000 members in more than 600 clubs in the United States, Canada, the Bahamas, Bermuda, Japan, and the United Kingdom. Pilot clubs sponsor activities to improve the civic, social, industrial, and commercial welfare of communities. Pilot International also sponsors a youth organization—Anchor Club for high school students.

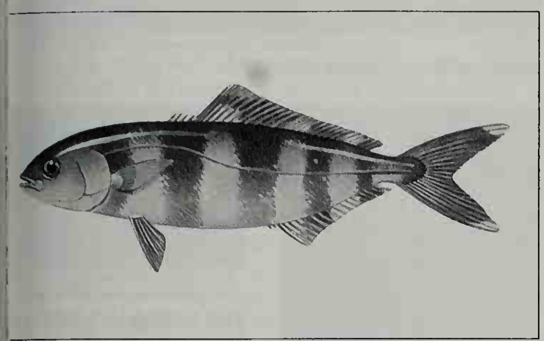
Pilot International was founded in 1921 in Macon, Georgia. In 1975, the organization established the Pilot International Foundation to improve the lives of people with disabilities. A special focus for the foundation is helping people with brain disorders. Pilot International has its headquarters in Macon.

Critically reviewed by Pilot International

Pilot whale is one of the largest members of the dolphin family. The animal may grow 14 to 21 feet (4 to 6 meters) long and weigh $\frac{3}{4}$ to $2\frac{1}{2}$ tons (0.7 to 2.3 metric tons). A pilot whale is black, with a white streak down its underside. Its head has an organ called a *melon* that is made of fatty tissue. The melon helps the animal locate objects in the water (see **Dolphin** [The bodies of dolphins]).

Pilot whales swim in groups called schools. Large numbers of pilot whales often strand themselves on beaches. Scientists, however, are not certain what causes this behavior. Pilot whales are sometimes called *blackfish,* a name that also refers to various kinds of true fish and to the killer whale (see **Killer whale**).

John K. B. Ford



Scientific classification. Pilot whales make up the genus *Globicephala* in the dolphin family, Delphinidae.

Pilotfish is a kind of fish found near the surface in most tropical seas and the warmer temperate seas. It can also be found off the coasts of the Americas from Cape Cod to Brazil. Most pilotfish are approximately 1 foot (30 centimeters) long. They are white to bluish-white with five or six dark vertical bands. The pilotfish got its name because it follows ships, sharks, turtles,

iłsudski, *peel SOOT skee,* **Józef,** *YOO zehf* (1867-935), a Polish patriot, led a movement to liberate Poland om Russia and helped unite his country. Piłsudski was ɔland's first head of state and military commander in ıief after the country achieved independence in 1918.

Poland's new democratic constitution of 1921 providǀd for a weak presidency. Piłsudski refused to run for e office. He withdrew from politics, and he resigned head of the military in 1923. But in 1926 he led a miliry overthrow of the government. He became premier ıd served until 1928. In 1930, he became premier again. om 1926 until his death, however, Piłsudski kept the al power of the government in his own hands.

Piłsudski was born on Dec. 5, 1867, near Vilnius, now Lithuania. He became a professional revolutionary in s youth. In 1887, he was arrested by the Russians and iled to Siberia for plotting to kill Russian Czar Alexaner III. But Piłsudski was not involved in the plot. After s release in 1892, he joined the new Polish Socialist ırty. In 1894, he became editor of the party's illegal ewspaper *Robotnik (The Worker).* The Russians arrestl him again in 1900 and sent him to an insane asylum hen he pretended to be insane. He escaped in 1901.

During World War I (1914-1918), Piłsudski fought at e head of the Polish Legions he had organized and ald with Germany and Austria-Hungary. In 1917, the ermans arrested him after he ordered his troops to fuse an oath of loyalty to the German and Austrian aries. Piłsudski was imprisoned until the end of the war.

After the collapse of Germany and Austria-Hungary in e war, Piłsudski became a national hero and headed e Polish provisional government. Later, as chief of ıte and military commander in chief, he led an armed uggle against Russia to establish Poland's borders. In s last years, he increased the presidential powers and nited those of parliament. John J. Kulczycki

ltdown hoax was a great deception in the study of ehistoric people. Between 1908 and 1912, parts of a ull and of a jawbone were found in a gravel pit at Piltwn in Sussex, England. Some scientists believed the mains came from a form of human being who lived 0,000 years ago. Others disagreed. But Piltdown "fos-" became famous as a "missing link" between physically modern human beings and the apes.

After years of controversy, scientists used newly developed chemical tests on the remains. They learned that the jaw came from a modern ape and that the human skull was much younger than the gravel in which it had been found. In 1955, radiocarbon tests dated the skull at A.D. 1230. Apparently, a prankster had buried an orangutan's jaw and a skull from a medieval cemetery. The jaw had been stained to make it look old and the teeth filed to make them look human. Karl W. Butzer

Pima Indians, *PEE muh,* are an agricultural people who live along the Gila and Salt rivers in southern Arizona. Since ancient times, the Pima and their ancestors have used the water from these rivers to irrigate their fields. The Pima call themselves *Akimuhli Au'autam,* which means *River People.*

The Pima are descended from the Hohokam, a farming people who dug long irrigation canals to bring water to their crops. The Hohokam also were wealthy traders and skilled craftworkers. After the Spaniards came to the New World, they spread Old World diseases that destroyed most Hohokam communities during the 1500's. The Hohokam Pima National Monument includes the remains of a Hohokam settlement.

The Pima added wheat and other crops brought by Europeans to those raised by the Hohokam. The Pima were powerful warriors and organized mounted patrols to protect their farms from Apache raiders. The Pima helped many white settlers. During the California gold rush of 1849, Pima warriors shielded the gold seekers crossing their territory. The Pima also sold supplies to wagon trains, served as scouts for the U.S. Army, and guarded white farmers from attacks by other tribes. But the whites took scarce river water and used it for their own fields. The loss of water ruined many crops and drove many of the Pima into poverty.

According to the 2000 U.S. census, there are about 8,500 Pima. Many live on the Gila River and Salt River reservations near Phoenix. Many work as farmers or unskilled laborers. An elected council governs each reservation. Henry F. Dobyns

Pimento, *puh MEHN toh,* is the popular name of a small evergreen tree of the myrtle family. A spice known as allspice, Jamaica pepper, or pimento comes from this tree. This spice is most commonly used for making pickles and baked goods, and for preserving meat products. The red fleshy pimento used to stuff green olives does not come from the pimento tree. That condiment, which is also known as red pepper or capsicum, is the fruit of a plant called capsicum.

WORLD BOOK illustration by John D. Dawson
The pimento bears small berries used to make the spice called *allspice, Jamaica pepper,* or *pimento.*

The name of the pimento tree comes from *pimienta,* the Spanish word for peppercorns. The tree is native to the West Indies and to Central Amer-

ica. Most commercial pimento spice comes from Jamaica.

Most pimento trees grow to a height of 20 to 30 feet (6 to 9 meters). The slender, upright trunk of the pimento is covered with smooth gray bark. The shiny, oval leaves have a pleasant odor when fresh. The fruit is a small berry about the size of a black currant. It is dark brown or black, glossy, sweet, and juicy when ripe. The dried, green unripe berry is used for the commercial spice.

Scientific classification. The pimento is in the myrtle family, Myrtaceae. It is *Pimenta dioica.* David S. Seigler

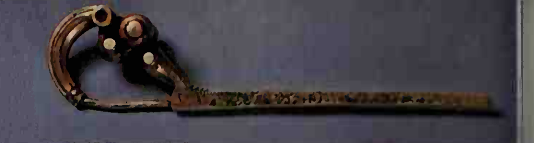
See also **Allspice.**

Pimpernel, *PIHM puhr nehl,* is a small annual plant that grows wild in Europe and Asia. It is sometimes planted in flower gardens of North America and often runs wild. The plant is low and spreading, with oval leaves in pairs on the stem. The small, bell-shaped flowers grow along the stem. There are several varieties, with red, scarlet, blue, or white flowers. Another name for the pimpernel is *poor-man's weatherglass.* This name refers to the flowers' habit of closing at the approach of cloudy or rainy weather.

Scientific classification. The pimpernel belongs to the primrose family, Primulaceae. It is classified as *Anagallis arvensis.* James S. Miller

Pimple is a red, raised skin blemish that usually contains pus. The most common cause of pimples is *acne,* a skin disorder that frequently occurs among teen-agers.

Acne consists of various kinds of blemishes that appear on the face, upper chest, and back. It is caused by hormone changes during the teen years. One kind of hormone stimulates the oil glands, which then grow larger and produce much oil. The *pores* (openings) of the oil glands at the skin surface are easily plugged, and oil accumulates under the plugs. A plugged pore forms a blemish called a *blackhead* or *whitehead.* Pimples are caused by the *acne bacillus,* a germ that thrives in the backed-up oil. The germ makes irritating substances from the oil, causing redness and pus. Mild acne can be treated by washing affected areas regularly and using such nonprescription medicines as benzoyl peroxide. Severe acne should be treated by a doctor. Pimples should not be squeezed. Squeezing may cause scarring.



Other causes of pimples include infections by *staphylococcal* and *streptococcal* bacteria. Unlike acne, in which there are many blemishes, these infections usually start with one pimple. This pimple may develop into a boil. Doctors treat these infections with antibiotics.

Many black men with curly facial hair develop pimples where they shave. These painful "shaving bumps" occur because the coarse, curved whiskers tend to grow into the skin after shaving. Growing a beard relieves this condition. Yelva Liptzin Lynfield

Pin is a short, pointed piece of metal. Pins are used mainly to hold two or more pieces of material together. People also wear pins as jewelry.

There are many kinds of pins. The most common types are *straight pins* and *safety pins.* These pins are usually made of steel or brass. Straight pins have a flat head at one end and a point at the other end. Straight pins are used primarily by seamstresses and tailors to fasten patterns to fabrics and to hold layers together before they are sewn. Safety pins have an oval shape. The point of the pin snaps into a protective guard to prevent the pin from falling out of the fabric and to avoid injuries. Safety pins are used mainly as temporary fasteners.

Various types of pins have been produced through the centuries, but their chief uses have remained unchanged. Pins are still used for decoration and to hold pieces of material together.

Pins were one of the earliest types of jewelry. People began wearing pins at least 20,000 years ago. Prehistoric people made pins from splinters of bones, wood, and thorns. Later pins were formed out of iron and bronze. The ancient Greeks and Romans used pins called *fibulae,* which resembled modern safety pins, to hold their garments together. Through the years, various types of decorative pins have been developed. For example, large ornamental pins called *brooches* were popular in the 1800's. At that time, women wore them at the center of the bust, but today they use them to adorn their coat lapels. Straight pins known as *stickpins* were originally used in the 1800's and early 1900's to hold men's ties and cravats in place. Today, these pins, which have gems, initials, or emblems of organizations at the top, are worn by women as accessories on scarfs and lapels.

Pins were handmade until the early 1830's. In 1832, the American inventor John Ireland Howe patented one of the first practical machines for manufacturing pins. In 1849, Walter Hunt, another American inventor, patented a design that served as the basis for modern safety pins. Lois M. Gurel

Pinchback, P. B. S. (1837-1921), was an American politician. In 1872, he became the first black to serve as governor of a state of the United States. Pinchback, a Republican, had become lieutenant governor of Louisiana in 1871. He served as acting governor for six weeks in 1872 and 1873 following the impeachment of Governor Henry C. Warmoth.

Pinchback won election to the United States House of epresentatives in 1872 and to the United States Senate 1873. His opponents charged that laws had been vioted in both of the elections. Both the House and the enate denied Pinchback membership, though white ouisiana officials who were chosen by the same proceures were declared legally elected. From 1870 to 1881, inchback published a weekly newspaper, *The* (New Orans) *Louisianian.*

Pinckney Benton Stewart Pinchback was born in lacon, Ga. His mother, a former slave, had been freed y his father, a wealthy white planter. Otey M. Scruggs

inching bug. See Stag beetle.

inchot, *PIHN shoh,* **Gifford** (1865-1946), an American onservationist and politician, was one of the first govrnment leaders to promote the scientific management f forests in the United States. In 1898, President Theoore Roosevelt appointed him chief of the Division of orestry, which became the U.S. Forest Service in 1905. nchot led the Forest Service until 1910. At the urging f Pinchot and others, Roosevelt greatly expanded the ation's forest reserves. In 1908, Pinchot became chairan of the National Conservation Commission, which ade the first inventory of the nation's natural reurces. Pinchot also served as governor of Pennsylvaa, from 1923 to 1927 and from 1931 to 1935.

Pinchot was born in Simsbury, Conn., and graduated om Yale University in 1889. He studied forestry in ance and other European countries. Pinchot wrote *The ght for Conservation* (1910). Robert W. Cherny

See also Taft, William Howard (Legislative defeats).

inckney, Charles (1757-1824), was a South Carolina gner of the Constitution of the United States. At the je of 29, he was one of the youngest delegates at the onstitutional Convention of 1787. Pinckney submitted s own plan for a new federal government. The plan as not adopted, but at least 30 of his suggestions were cluded in the final version of the Constitution.

Pinckney was born into a prominent plantation family Charleston, S.C. He was educated in Charleston and ter practiced law there. Pinckney became a lieutenant the Revolutionary War in America (1775-1783). The itish captured him in the fall of Charleston in 1780 and pt him imprisoned until 1781. From 1784 to 1787, nckney was a delegate to the Congress of the Confedation. He won election as governor of South Carolina ur times, serving from 1789 to 1792, from 1796 to 1798, d from 1806 to 1808. Pinckney was a U.S. senator from 98 to 1801 and a U.S. representative from 1819 to 1821. e served as U.S. minister to Spain from 1801 to 1805. s cousin Charles Cotesworth Pinckney also signed the onstitution. W. Calvin Smith

nckney, Charles Cotesworth (1746-1825), a anter, politician, and diplomat, was a South Carolina gner of the Constitution of the United States. An influtial delegate at the Constitutional Convention of 1787, nckney supported a strong national government and e power of the Senate to *ratify* (approve) treaties. He o helped settle the dispute between the Northern and uthern states over regulation of the foreign slave de (see **Constitution of the United States** [The mpromises]). He later helped win ratification of the nstitution by South Carolina. Pinckney's cousin arles Pinckney was also a signer of the Constitution.

Pinckney was born in Charleston, S.C. He was educated in Britain and France, but returned to South Carolina to practice law. During the Revolutionary War in America (1775-1783), he rose to the rank of brigadier general. He was taken prisoner when the British captured Charleston in 1780, and was held for two years.

In 1796, Pinckney accepted a position as U.S. minister to France. But the French refused to receive him. The next year, President John Adams appointed Pinckney as one of three special commissioners to resolve differences between the United States and France. French negotiating agents demanded a loan to France and a bribe for the French statesman Prince Talleyrand. Pinckney's reply to their demands was "No! No! Not a sixpence!" This negotiation attempt came to be known as the *XYZ Affair* (see **XYZ Affair**).

Pinckney ran as a Federalist candidate in three presidential elections. He lost to Thomas Jefferson in 1800 and 1804 and to James Madison in 1808. W. Calvin Smith

Pinckney, Elizabeth Lucas (1722-1793), a colonial planter of South Carolina, did much to promote the economic growth of South Carolina in the 1700's. She successfully developed and grew indigo plants on her father's plantations. The blue dye produced from the plant was in great demand in Europe. Pinckney shared her knowledge with other South Carolina farmers and helped indigo become a leading export for the colony.

Pinckney was probably born in Antigua, then a British colony in the West Indies. Her father, George Lucas, served as the lieutenant governor there. In 1738, Lucas brought his family to South Carolina, where he had inherited three plantations near Charleston. The next year, he returned to Antigua, leaving Elizabeth, then 16 years old, in charge of the plantations. In 1744, Elizabeth married Charles Pinckney, a planter and lawyer. Among their children were two future statesmen, Charles Cotesworth Pinckney and Thomas Pinckney. After Elizabeth's husband died in 1758, she successfully managed the Carolina plantations for the next 35 years. She died in Philadelphia. President George Washington, who had met her on a tour of the South in 1791, served as a pallbearer at his own request. W. Calvin Smith

Pinckney, Thomas (1750-1828), was an American soldier, statesman, and diplomat. He arranged the Treaty of San Lorenzo, also known as the *Pinckney Treaty,* with Spain in 1795 (see **Pinckney Treaty**). He ran as a Federalist candidate in the presidential election of 1796, which was won by John Adams.

Pinckney was born in Charleston, S.C., and educated in Britain and France. He fought in the Revolutionary War in America from 1775 to 1781, and rose to the rank of major. Pinckney was governor of South Carolina from 1787 to 1789 and became the U.S. minister to Great Britain in 1792. He was a U. S. representative from 1797 to 1801. His brother Charles Cotesworth Pinckney and his cousin Charles Pinckney were signers of the Constitution of the United States. W. Calvin Smith

Pinckney Treaty was an agreement ending disputes between the United States and Spain over possession of the Florida area and the mouth of the Mississippi River. The treaty, whose formal name was the Treaty of San Lorenzo, was signed on Oct. 27, 1795. Spain recognized the 31st parallel, the northern border of Florida, as the southern boundary of the United States. Spain agreed to

let Americans land goods at New Orleans free of taxes for a period of three years. The two nations also agreed that this right could be renewed. Both nations gained free use of the Mississippi. Donna J. Spindel

Pindar, *PIHN duhr* (522?-443 B.C.), was the greatest lyric poet of ancient Greece. He is generally credited with inventing the Pindaric ode. This type of ode is built of three stanzas—the *strophe, antistrophe,* and *epode*—repeated in series. Pindar wrote these stately, intricate poems in praise of various events, such as an athletic victory at the great national games.

Pindar's odes were intended for elaborate performance, with music and dance, when the victor returned to his native city. They are unlike other poetry, except for some choral lyrics in the tragedies of the dramatist Aeschylus. Standard elements include praise of the victor, often combined with veiled advice; the telling of a myth; and praise of the gods. The odes are perfect in form and beautiful in their intricate language, but lose much in translation. Most of Pindar's other poetry was lost.

Pindar was born of a noble family in Cynoscephalae near Thebes. His fame was so great that when Alexander the Great burned Thebes to the ground, Pindar's house was the only one spared. Pindar was a deeply religious man who wrote of the immortality of the soul and judgment by the gods after death. In politics, he was conservative and antidemocratic. Cynthia W. Shelmerdine

Pindus Mountains. See Greece (The land).

Pine is any of a large group of evergreen trees that have needlelike leaves and bear cones. There are about 100 species of pines. Almost all of them grow naturally only in the Northern Hemisphere. Pines are found in a wide range of environments, but they most often grow in sandy or rocky soils. They are especially common in the mountains of western and southeastern North America, southern Europe, and southeastern Asia. Some pines reach heights of about 200 feet (61 meters). Others are small and shrublike.

Pines belong to a group of plants called *conifers.* All conifers reproduce by means of cones that produce pollen and seeds. A pine differs from other conifers in the way its leaves grow. Nearly all pines have needles that grow in bundles of two, three, or five each. The leaves of other conifers grow in larger bundles or do not form bundles. Conifers closely related to pines include firs, larches, and spruces.

Pine trees bear both male and female cones. The male cones typically measure less than 1 inch (2.5 centimeters) in length. The female cones are much larger and have woody scales. When people speak of "pine cones," they usually are referring to the female cones. In the spring, the male cones produce enormous quantities of pollen. The wind carries the pollen to egg cells attached to the scales of the female cones. The pollen fertilizes the egg cells, which then develop into seeds. The seeds take one or two years to mature. The mature seeds of most pines have winglike parts that cause the seeds to twirl and float in the wind. Pine seeds may blow as far as 300 feet (91 meters) from the parent tree.

Pines rank as the world's most important source of timber. Most pines grow rapidly and form straight, tall trunks that are ideal for lumber. Some pines produce *resin,* a substance used to make such products as turpentine, paint, and soap. The wood of many pine species makes excellent pulp for the manufacture of pape[r]. Pines are also grown as shade trees.

North American pines

About 65 species of pines are native to North America. Thirty-six of them grow in the United States. Botanists divide pines into two groups: (1) soft pines and (2) hard pines. The trees of these groups differ mainly in the way their needles grow.

Soft pines, also called *white pines,* typically produce needles in bundles of five. Hard pines, also known as *yellow pines,* ordinarily produce needles in bundles of two or three. In addition, hard pines generally have heavier, harder wood than soft pines.

Both hard and soft pines grow naturally in areas throughout North America. This article divides North American pines into three groups: (1) eastern pines, (2) southeastern pines, and (3) western pines.

Eastern pines. The *eastern white pine* is the only so[ft] pine native to eastern North America. It is common in New England and grows as far west as Minnesota and as far south as northern Georgia. This huge, majestic tree may reach a height of over 100 feet (30 meters) and measure more than 4 feet (1.2 meters) in diameter at its base. It has long, slender cones and is prized for its white, smooth-grained lumber.

Two important hard pines that grow in Canada and the northeastern part of the United States are the *red pine* and the *jack pine.* The red pine is found in areas near the Great Lakes, in New England, and in southeastern Canada. It gets its name from its reddish-brown bark. It has long needles that grow in bundles of two and is an important timber tree. The jack pine grows chiefly in sandy soils from the northern Great Lakes region to northwestern Canada. Its needles grow in bundles of two and it bears small, curved cones. The cones may remain closed and hold their seeds for many year[s]. The jack pine is often one of the first trees to grow afte[r] wildfires. The heat of such fires causes the cones to open, releasing the seeds that produce new trees. The wood of the jack pine is used for paper pulp.

The *pitch pine* grows in sandy soils in New England and in shallow soils in the southern Appalachian Mour[n]tains. Its cones are spiny and measure about 4 inches ([1]0 centimeters) long. Its needles grow in bundles of three.

Southeastern pines. Pines grow throughout the Southeastern United States. The *Virginia pine* is found [in] the southern Appalachian Mountains and the rolling hills of the Piedmont Region. It has scaly bark, and its cones measure about 2 inches (5 centimeters) in length. Its needles grow in bundles of two. The *shortleaf pine* grows in the same area as the Virginia pine but is a much taller tree. It may reach a height of over 100 feet (30 meters). Its bark is divided into irregular plates, and its needles grow in bundles of two or three. The *loblol[ly] pine* thrives in many environments throughout the Southeast. It resembles the shortleaf pine, but its needles always grow in bundles of three. These three pines all grow rapidly and are common in abandoned fields and pastures. All are important sources of lumber.

Many pine species grow in the sandy soils of the Atlantic and Gulf coastal plains. The *longleaf pine* grows [in] particularly sandy soils. It has large cones and extreme[ly] long needles that may reach a length of 18 inches (46

Josef Muench

A forest of pine trees is a place of unusual beauty. This photograph shows a forest of ponderosa pines in the San Francisco Mountains of Arizona. In the foreground, pine cones lie on the snow-covered forest floor.

ntimeters). The *slash pine* grows in somewhat moister ils. Its needles and cones are smaller than those of the ngleaf pine. Both species are important sources of nber and resin. The *pond pine* grows in swampy eas. It can grow back from its roots after the above-ound part of the tree has been destroyed by fire.

Western pines. Many species of pines grow in the ountains of western North America. Different species e found at different elevations. The *Digger pine* grows lower elevations in the Sierra Nevada and in the Coast nges of California. This tree has needles that grow in ndles of three and cones that may measure as much 10 inches (25 centimeters) in length. Digger pine eds were once an important food for Indians.

A number of important pines grow at slightly higher evations than the digger pine. The *ponderosa pine* is mmon throughout the Rocky Mountains and the east- side of the Cascades, and in the Southwestern ited States. This hard pine grows up to 130 feet (40 ters) tall and produces high-quality lumber. Its nee-s grow in bundles of three, and its cones are about 5 inches (13 centimeters) long. The *sugar pine* and the *western white pine* are found at middle elevations in the Sierra Nevada. The sugar pine produces the longest cones of any North American pine. They may reach nearly 30 inches (76 centimeters) in length. The *lodgepole pine* grows at higher elevations than the ponderosa pine in the Sierra Nevada and the Rocky Mountains. It thrives in sandy soils and its needles grow in bundles of two. Its small cones may remain closed for years after they mature, and its seeds are released in wildfires.

The *limber pine* and the *whitebark pine* are found in the Rocky Mountains at some of the highest elevations at which trees can grow. In areas exposed to strong winds and extreme cold, these two soft pines grow to only about 5 feet (1.5 meters) in height. Elsewhere, they grow 30 to 50 feet (9 to 15 meters) tall. Another soft pine found at extremely high elevations is the *bristlecone pine.* Some are among the oldest living things. A number have lived over 4,000 years. See **Bristlecone pine.**

Several species of pines grow naturally only in small

areas of southern California. For example, the *Monterey pine* is native to a small area on the California coast. In this area, its wood has little commercial value. However, this tree has been introduced into the Southern Hemisphere and now ranks as a major source of timber in Australia, Chile, New Zealand, and South Africa.

Other pines

Only a few pine species grow in northern Europe. The *Scotch pine*, a valuable timber tree, is probably the most important of these. This pine also is grown in many areas of North America, where it is widely used as a Christmas tree.

Many species of pines grow in the countries that border the Mediterranean Sea. The *black pine*, also called the *Austrian pine*, is an important source of timber in this region. It also is cultivated worldwide as an ornamental tree. The *Aleppo pine* is the most widespread pine of the Mediterranean region. It grows from Spain and northern Africa near the Strait of Gibraltar to the mountains of Israel and Lebanon.

About 15 pine species grow naturally in southeastern Asia and Japan. Most of them grow in mountainous areas. In northern Asia, the Siberian pine ranks as an important pine species. This pine grows from the Ural Mountains through western and central Siberia to northern Mongolia. Norman L. Christensen, Jr.

Scientific classification. Pines are in the pine family, Pinaceae. They make up the genus *pinus*.

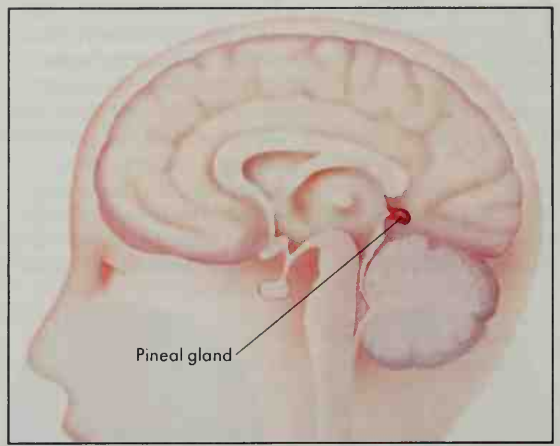
Pine siskin

Pine-tree shilling was a silver coin minted by colonists in Boston, in the Massachusetts Bay Colony, from 1667 to 1682. A pine tree encircled by the word *Masathusets* appeared on one side of the coin. The other side bore the Roman numeral *XII* and the date *1652*. The XII stood for twelve pence, which equaled one shilling. The date 1652 was probably used so that the colonists could claim the coins were minted legally. Under English law, only the monarch was allowed to issue coins. However, King Charles I had been executed in 1649, and Charles II did not succeed him until 1660 (see **England** [History]). Thus, the colonists could claim the coins were minted at a time when royal authority did not exist.

WORLD BOOK photo by James Simek



The pine-tree shilling was a colonial silver coin. It had a pine tree on one side and the date 1652 on the other side.

The pine-tree shilling was also called the *Boston shilling* and the *Bay shilling*. Three-penny and six-penny pieces made during the same period bore the same design. R. G. Doty

Pineal gland, *PIHN ee uhl,* also called *pineal body,* is a tiny organ in the brain of human beings and most other *vertebrates* (animals with a backbone). Scientists are uncertain of the function of the pineal gland in human beings. They believe it plays a role in a variety of important body functions, including certain reproductive processes. In most other vertebrates, the pineal gland helps regulate certain daily and seasonal body cycles.

The pineal gland secretes a hormone called *melatonin.* Its production of melatonin varies with periods of light and darkness in the environment. In most amphibians, birds, fishes, and reptiles, the gland is located in the back of the head just beneath the skin. It responds directly to light that penetrates the skin. In mammals, including human beings, the pineal gland lies near the center of the brain. It obtains information about light in the environment by means of nerve pathways originating in the eyes. In general, light slows and darkness stimulates the pineal gland's production of melatonin. Therefore, the gland tends to secrete small amounts of melatonin during the day and large amounts at night.

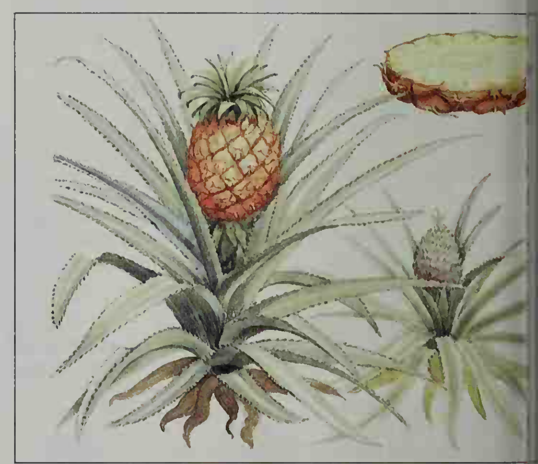
In most vertebrates, the pineal gland's secretion of melatonin keeps the animal "timed" to its environment. Most animals live under conditions where the daylength and the temperature of the environment change throughout the year. To survive, they must breed at certain times of the year, usually spring or early summer. The offspring will then have a chance to grow strong enough to survive the first winter. The pineal gland keeps track of the changing daylengths. By means of its melatonin, it sends this information to the body and

WORLD BOOK illustration by Charles Wellek

The pineal gland is located near the center of the brain in human beings. It secretes *melatonin,* a hormone believed to play an important role in a person's sexual development.

appropriate reproductive responses are made.

In human beings, melatonin has been linked to the onset of *puberty,* the stage of life when a person matures sexually. Studies have shown that the pineal gland's nightly secretion of melatonin decreases when a boy or girl reaches puberty. Other studies have indicated that melatonin may help regulate menstrual cycles in women and sperm production in men. In addition, researchers have suggested a connection between melatonin levels and certain mental illnesses. Russel J. Reiter



Pineapple is a tropical plant known for its juicy, fragrant fruit. It probably received its name because the fruit looks like a large pine cone. Many people enjoy drinking the juice of the pineapple and eating the fruit as a dessert or in salads. Thailand grows more pineapples than any other country. Farmers there produce about one-fourth of the world's pineapples.

The pineapple plant grows from 2 to 3 feet (61 to 91 centimeters) tall, and the fruit weighs from 4 to 8 pounds (2 to 4 kilograms). The ripe fruit has a greenish-orange, yellowish-green, or dark green *shell* (skin). At the top of the fruit is a group of small leaves called the *crown.* The flesh of the fruit, the part eaten by people, is firm and pale yellow, though it may be white. The most widely grown kind of pineapple, *Smooth Cayenne,* is seedless, but some varieties have small brown seeds beneath the shell.

A pineapple plant has blue-green, sword-shaped leaves that grow around a thick stem. The edges of the leaves of most varieties of pineapples have sharp spines. But the leaves of the *Smooth Cayenne* have spines only at the tips and bases. The pineapple plant has underground roots and small roots that grow aboveground.

When the plant is from 14 to 16 months old, an *inflorescence* (flower stalk with tiny flowers attached) appears in the center. The inflorescence resembles a small pink-red cone. After the inflorescence has grown about 2 inches (5 centimeters) high, blue-violet flowers begin to open. Each flower blooms for only one day. All the flowers open within 20 to 30 days. Each flower develops into a fruitlet. The fleshy parts of the fruitlets unite with the stalk to which they were attached. This combination of fruitlets is called a *multiple fruit.* The multiple fruit and the stalk forms the yellow center of the pineapple. The pineapple's shell develops from thick, hard, leaflike structures called *floral bracts.*

Cultivation and production. Pineapple plants need a warm climate and well-drained soil. Too much water can harm them, but irrigation is necessary in some dry regions. Before planting, pineapple growers plow the land deeply and break it up well. In Hawaii and some other regions, they use a machine to put certain chemicals into the soil to kill harmful roundworms called *nematodes.* The same machine also deposits fertilizer and lays wide strips of plastic on the ground. The plastic strips keep the chemicals from escaping from the soil. The plastic also conserves moisture, keeps the soil

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists

ırm, and discourages the growth of weeds.

Pineapples are grown from any of four parts of a neapple plant: (1) *shoots,* (2) *slips,* (3) *crowns,* and (4) *ckers.* Shoots grow from the main stem. Slips grow om the flower stalk just below the fruit. Crowns are the oups of leaves at the top of the pineapple. Suckers se from the roots below ground.

Workers insert the shoots, slips, crowns, or suckers ough the plastic strips by hand. They punch holes in e plastic with a planting tool. After planting, pineapple ınts require careful cultivation. Growers may use hor-onelike chemicals to make the plants flower and pro-ce fruit faster than they would naturally. Machines do ost of the weeding, spraying, and fertilizing that used be done by hand. About 20 months after planting, the ıeapples are ready to be picked. A pineapple plant ars one fruit for the first harvest and may bear two its for the second or third harvest. Most planters re-ınt fields after every two or three harvests.

In most countries, pineapples are harvested by hand. ıeapple pickers grab the fruit by the crown and twist rom the stalk. They put the pineapples in baskets apped to their backs or in canvas bags carried over shoulder. Hawaiian pineapple growers use a *har-ster-conveyor* to simplify the fruit-picking. This ma-ne consists of a long *boom* (metal arm) with a convey-belt built into it. A truck moves the boom through the ıeapple field, with the boom extending over many vs of plants. Pineapple pickers walk behind the boom. ey pick the pineapples and drop them onto the con-vor belt, which carries them to the truck.

At the cannery, the pineapples are washed and sorted size. A machine called a *Ginaca* removes the shells, ıches out the cores, and cuts off the ends of the eapples. Next, the fruit is cut into slices or pieces. en it is put in cans, syrup is added, and the cans are led. The unsweetened juice from the pineapple es is also canned. Finally, the cans are heated to kill microorganisms that might cause spoilage.

Pineapple plants also have several other uses. Various ts of the plant are used to make cattle feed, meat ten-izers, and medicines. In the Philippines, people ave the fibers of the plant into a cloth called *piña.*

History. Many scientists believe that pineapples origi-ed in Brazil. Christopher Columbus and his crew, o explored the West Indies in 1493, were probably first Europeans to taste the fruit. Europeans later nd pineapples throughout most of South and Central erica and the West Indies. They took the fruit to Eu-e and planted it in hothouses. It became a favorite t of royalty and the wealthy.

Commercial production of pineapples began in the -1800's in Australia, the Azores, and South Africa. To-the world's chief pineapple producers include zil, China, Côte d'Ivoire, Indonesia, Malaysia, Mexico, Philippines, South Africa, Thailand, and the United es. Plantations in Hawaii produce most pineapples are grown in the United States. Michael J. Tanabe

Scientific classification. The pineapple belongs to the neliad family, Bromeliaceae. Its scientific name is *Ananas co-us.*

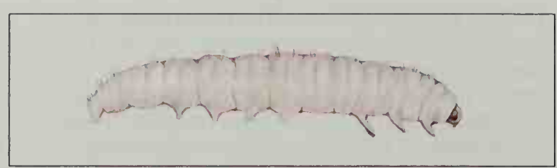
P ero, *puh NEER oh,* **Arthur Wing** (1855-1934), was a skillful and highly productive English playwright. He became popular at first for comedies and later for "problem plays," in which he explored various social problems of his day. The problem plays helped pave the way for serious drama in England. Prior to 1910, Pinero's success in England rivaled that of his contemporary, George Bernard Shaw.

Pinero gained great popularity for the comedy *The Magistrate* (1885); *Dandy Dick* (1887), one of his many farces; and the sentimental romance *Sweet Lavender* (1888). Later hits included the sentimental comedy *Trelawny of the "Wells"* (1898) and *The Gay Lord Quex* (1899), one of his finest comedies. Pinero's most popular problem plays included *The Second Mrs. Tanqueray* (1893) and *His House in Order* (1906). His problem plays are now considered outdated, but theater companies occasionally revive his comedies. Pinero was born in London. King Edward VII knighted him in 1909, and he became known as Sir Arthur Pinero. Charles A. Berst

Ping-pong. See **Table tennis.**

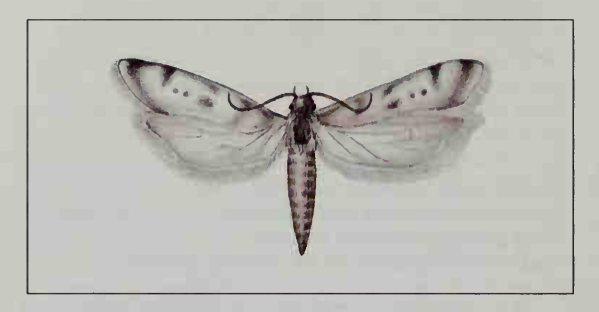
Pink is a group of about 300 species of flowering plants that botanists have named *Dianthus,* the Greek word for *Jove's flower.* The blossoms of these flowers are often seen in shades of pink. But the name *pink,* according to many authorities, is used in the sense of *pierce,* or *puncture,* and refers to the crinkled edges of the petals. The group includes several favorite garden flowers admired for their beauty and delicate scent. The spicy fragrance of many old-fashioned gardens comes from clove pinks, clustered in their grasslike leaves and showing combinations of pink, white, and red. The cultivated pinks include the *carnation;* derivatives of the *common,* or *feather, pink; clove pinks; rainbow pinks;* small-flowered *maiden pinks;* and *sweet Williams,* or *bunch pinks.* Pinks are grown from seeds and cuttings. See also **Baby's-breath; Carnation; Sweet William.**



W. Dennis Clark

Scientific classification. Pinks belong to the pink family, Caryophyllaceae. The scientific name for the parent of the cultivated carnation is *Dianthus caryophyllus.* The common pink is *D. plumarius;* the rainbow pink, *D. chinensis;* the maiden pink, *D. deltoides;* the sweet William, *D. barbatus.*

Pink bollworm is an insect that attacks cotton plants in many parts of the world. The feeding of this insect reduces the yield and quality of cotton lint and the oil content of the seeds. Experts believe the pink bollworm was imported from Egypt into Mexico in 1911 in shipments of cotton seed. The insect was first discovered in the United States in Texas in 1917. Large sums of money have been spent in an effort to kill the pink bollworm in the United States.



The adult is a small grayish-brown moth, with a wingspread of about $\frac{3}{5}$ inch (15 millimeters). The larva is about $\frac{1}{2}$ inch (13 millimeters) long. The eggs are laid on all parts of the cotton plant. When the larvae hatch, they feed on the pollen and fleshy parts of the flower. The infested flowers do not open normally, and many fall off. Later, the larvae enter the growing cotton bolls, eat the seeds, burrow through the lint, and interfere with the growth of the bolls. This causes the cotton to rot.

In spring and summer, the larvae mature in 8 to 16 days. Those hatched in fall and winter may remain as larvae from a few months to two years or more. When the summer larvae are grown, they leave the bolls. They

spend the third, or pupal, stage of their lives about 3 inches (8 centimeters) underground or under decaying leaves or other organic matter at the soil surface. The pupal period lasts from 6 to 20 days. The resting larvae mature in the ground or in the seed and lint inside the boll. The insect may be easily carried to any distance while in this resting larval stage. Breeding begins early in spring and continues until frost, with several generations produced in a season. John R. Meyer

Scientific classification. The pink cotton bollworm belongs to the gelechiid moth family, Gelechiidae. Its scientific name is *Pectinophora gossypiella.*

Pinkerton, Allan (1819-1884), an American detective, in 1850 established one of the first detective agencies in the United States. He first won fame for exposing the activities of a band of counterfeiters. In 1861, Pinkerton guarded Abraham Lincoln as he journeyed from Springfield, Illinois, to Washington, D.C., to be inaugurated as president. Soon after the outbreak of the American Civil War (1861-1865), Pinkerton helped organize a federal secret service. He also operated his own firm in Chicago, and established branches in several cities.

After the Civil War, Pinkerton organized groups of armed men known as "Pinkerton Men," whose services were available to employers at a daily fee. These forces broke labor strikes that occurred during the Reconstruction period. Members of labor unions hated the "Pinkerton Men" because these men were employed on the side of management against the unions.

Pinkerton also smashed several Western gangs. His earliest "Wild West" case ended with the capture of the Reno brothers, a gang of train robbers, in 1868.

Pinkerton was born on Aug. 25, 1819, in Glasgow, Scotland, and moved to the United States about 1842. In Illinois, he became deputy sheriff of Kane County and later of Cook County. His autobiographical writings include *Criminal Reminiscences and Detective Sketches* (1879) and *Thirty Years a Detective* (1884). James E. Sefton

Pinkeye. See Conjunctivitis.

Pinocchio. See Collodi, Carlo.

Pinochle, *PEE nuhk uhl* or *PEE nahk uhl,* is a card ga e played with a special deck consisting of 48 cards. Eac of the four suits has 12 cards, two each of every card from the nines through the aces. The aces are the hig est-ranking cards, followed by the tens, kings, queen jacks, and nines.

There are many variations of pinochle. One of the most popular forms of the game is *auction pinochle.* s played by three people, often with a fourth acting as dealer. The object of the game is to bid a certain num ber and then to reach that score. Players make points two ways. The winner of the bid *melds*—that is, the bi der lays down certain combinations of cards and sco the points they represent. After the hand has been played, the bidder also receives specified points for t cards in the tricks he or she has taken.

To begin play, the dealer gives 15 cards to each pla r and deals the remaining three, called the *widow,* face down. The player to the dealer's left bids first. The mi mum bid is usually set at 250. Every overbid must be multiple of 10, such as 260, 270, or 280. The player wh bids highest turns up the widow for the other players see and adds those cards to his or her hand. The bidd then names the trump suit and melds. The bidder ne discards three cards.

The bidder's opponents play as partners. The bidde picks up the meld cards and leads a card to start the fi trick. The other two players each play a card in turn, f lowing suit. A player who cannot follow suit must pla trump card. Each player, if able, must play a higher ra ing card than any cards previously played on the trick Each trick of three cards is taken by the person who plays the highest card in the suit led, or who trumps highest. If the two highest cards are alike, the one played first wins the trick.

A winning bidder collects a certain number of poin or chips from each opponent. The number, which va s according to local custom, is based on the size of the bid. A losing bidder pays each opponent twice this amount, or just once this amount if the bidder conce s defeat before playing out the hand. When spades are trumps, all points or chips gained and lost are double Double deck pinochle, with four players divided into partners, is another popular form. It uses two pinoch decks from which the nines have been removed. A si pler form of pinochle, with no bidding, is a popular t player game. R. Wayne Schmittberger

Piñon, *PIHN yuhn* or *PEEN yohn,* also spelled pinyo s the name of several species of small pines native to t Southwestern United States and Mexico. Piñons som times grow as sprawling shrubs, but they more ofter occur as small trees that measure 15 to 30 feet (5 to 9 meters) tall. Dry, open woodlands of piñons and junipers cover large areas of land that is too dry to support forests but not dry enough to be a true desert.

Piñons have short needles that grow singly or in cl ters. Piñon cones contain seeds, or *pine nuts,* with a d cate nutty flavor. Pine nuts form part of the traditional diet of Indians from the Southwest. Douglas G. Sprug

Scientific classification. Piñons belong to the pine family Pinaceae. The most common species are *Pinus monophylla,* *cembroides,* and *P. edulis.*

nter, Harold (1930-), is an English playwright. ; dramas emphasize a sense of unspoken and some-ıes unexplained tensions between the characters.

Pinter's early plays are often called "comedies of men-ː" because they show ordinary people threatened or ıcked by mysterious forces. In *The Birthday Party* 58), two sinister men hunt down a meek man living in oarding house and punish him for some unspecified ense. In *A Slight Ache* (1959), a silent but menacing ·elict frightens a wealthy man into a mental collapse. ıer early plays include *The Dumb Waiter* (1957), *The llection* (1962), and *The Lover* (1963).

n the 1960's, Pinter explored the ways in which rela-ıships often break down into power struggles. In *The Caretaker* (1960), two brothers and a tramp form constantly changing alliances against each other. In *The Homecoming* (1965), a son's visit with his wife to his family home leads to a rearrangement of the family power structure. In later plays, Pinter examined how conflicting memories of the past make it impossible to be sure of what really happened. These plays include *Old Times* (1971), *No Man's Land* (1975), and *Betrayal* (1978). In the 1980's, he turned to political subjects, attacking the repressive methods of totalitarian governments in such plays as *One for the Road* (1984) and *Mountain Language* (1988).

Pinter has written many screenplays. He is also a stage director and has acted occasionally. Pinter was born in London. Gerald M. Berkowitz

Pinto. See **Horse** (Coat and skin; picture).

Pinworm, also called *threadworm,* is a small roundworm. Pinworms are *parasites.* That is, they live in the body of other animals. They are about $\frac{3}{8}$ inch (9 millimeters) long and have white bodies and pointed tails. Some pinworms infect horses and rabbits. One type, *Enterobius vermicularis,* commonly infects humans.

The young worms live in the upper part of the large intestine. When the females are ready to lay eggs, they crawl down the rectum and out the intestinal opening called the *anus,* usually at night. They lay eggs on the surrounding skin. This movement causes skin swellings and severe itching. The eggs fall off onto the bedding or clothing, or may be picked up under fingernails in scratching. If the eggs are swallowed, they reach the intestine and become adult pinworms.

Pinworms are not very harmful unless they are present in large numbers. But their eggs may infect other people or reinfect the original carrier. In some areas, 10 to 60 per cent of the children may have pinworms at some time. Doctors use drugs to treat infection caused by pinworms.

Scientific classification. Pinworms belong to the family Oxyuridae and the phylum Nematoda. David F. Oetinger

Pioneer Clubs is an organization for girls and boys from preschool age to 17 years old. It conducts an interdenominational club program that teaches Christian principles and encourages personal growth through individual and group experience. The program centers around the motto *Christ in Every Phase of Life* and includes cultural, religious, and recreational activities.

Local clubs meet in churches and in about 25 camps throughout the United States and Canada. More than 100,000 girls and boys from about 2,500 churches of 80 denominations belong to the organization in those two countries. Clubs also operate in about 30 other nations. Every local club consists of five age divisions, each of which has a program for its age group. The Pioneer Clubs depend on adult volunteers for leaders, and the organization provides training sessions and educational materials for these leaders. This training information is available to youth leaders outside of the Pioneer Clubs.

The organization was founded in 1939 as Pioneer Girls. In 1981, it expanded its membership to include boys and the name was changed to Pioneer Clubs. Headquarters are at 27W 130 St. Charles Road, Wheaton, IL 60188. Critically reviewed by Pioneer Clubs

The pioneers pushed the frontier of the United States westward from the Appalachian Mountains to the Pacific Ocean. Most pioneer families traveled with several others who were making the same journey. West of the Mississippi River, many settlers who were headed for the Oregon region or California joined together to form caravans called *wagon trains, above.*

Pioneer life in America

Pioneer life in America. The story of the pioneers tells of the lives of thousands of ordinary people who pushed the frontier of the United States westward from the Appalachian Mountains to the Pacific Ocean. It is the tale of the many hardships and dangers and the isolation the settlers faced as they struggled to build new lives away from the civilization they had known in the East. It is also the story of a clash of peoples, as the pioneers sought to acquire lands where American Indians lived.

The pioneers played an important role in the history of the United States. They contributed much to America's knowledge about the geography, travel routes, and commercial possibilities of the West. They spread the political and social institutions and values of the new and growing nation across the continent. They also changed the look of the land as they cleared it for farms, roads, and towns. In addition, the pioneer settlement of America led to the loss of lands and traditional ways of life for many American Indians.

From about 1760 to about 1850, the pioneers moved westward in two large migrations. During the first migration, pioneers from the East Coast and from Europe advanced as far west as the Mississippi Valley. During the second migration, which began in the 1840's, settle from the East and Midwest migrated to the Oregon region and California. This article tells who the pioneers were, why they moved westward, and what their lives were like on the frontier. For the story of the first colonists, see **Colonial life in America.** For the history of s tlements in the West after 1850, see **Western frontier life in America.** See also **Westward movement in America.**

Jerome O. Steffen, the contributor of this article, is Professor of History at the University of Oklahoma.

Why the pioneers headed west

Pioneers moved west for a variety of reasons. Some went to the frontier in search of adventure. However, most pioneers headed west to make a better life for themselves and their children. They wanted to improv their social and economic position. Some hoped to ha more say in political affairs. Many young couples and single men sought their fortune on the frontier. Land was the chief form of wealth at the time, but it genera passed from father to oldest son. Even for those who had the money to buy land, good farmland was hard t

ind in the East. Across the Appalachians, however, settlers could obtain a plot of fertile land for a fraction of he cost of a similar piece in the East. In time, they might lecide to increase the size of their farms or sell them for profit.

The early settlers who crossed the Appalachian Aountains included people who were from Europe or vere of English, German, or Scandinavian descent. ome brought African-American slaves with them to the rontier. However, a number of pioneers were free black mericans who saw on the frontier a chance to start a ew life. Some of these African Americans had been reeased from slavery by their masters or by state legislaures. Others had bought their freedom or had run way. Many African Americans headed for the Northvest Territory, where slavery was illegal. The Northwest erritory, originally known as the Old Northwest, covred the area that is now Ohio, Indiana, Illinois, Michian, Wisconsin, and part of Minnesota.

However, some communities and territories passed ws that discriminated against African-American seters. For example, the Indiana Territory passed a law in 803 that prohibited blacks from testifying in any trial inolving whites.

Moving westward

Thousands of settlers crossed the Appalachian Mounins during the late 1700's and the early 1800's. These ioneers established frontier settlements in Kentucky, ennessee, Ohio, Indiana, Illinois, and other lands as far est as the Mississippi Valley. This section and the secons *A pioneer settlement* and *Pioneers and Indians* disiss this frontier. For the story of America's second big igration, to Oregon and California, see the section *rossing the Plains.*

Before the arrival of the pioneers. When the pioeers arrived in the region between the Appalachians id the Mississippi, they came upon a land of great natal beauty. Making up part of an area commonly called e Eastern Woodlands, the region had thick forests, arkling lakes and streams, and plentiful fish and game. ear the Mississippi River, the forest gave way to rolling prairie. The rich soil and adequate rainfall of the region made it well suited for farming.

The land between the Appalachians and the Mississippi River had been home to a number of American Indian cultures long before the pioneers arrived. The ancestors of some of these groups had come to the area as early as 10,000 B.C. The members of the powerful Iroquois League as well as such tribes as the Fox, Illinois, Sauk, and Shawnee inhabited the northern part of the region. The Cherokee and Chickasaw were among the tribes who lived farther south. The Indians of the Eastern Woodlands and nearby areas were farmers and hunters. They built permanent houses made of poles, bark, and mud. Many Native Americans lived in communities of several hundred people.

Stages of settlement. People of European descent came to the region between the Appalachians and the Mississippi River in several—often overlapping—stages. The first to visit the region were missionaries, fur traders, and explorers from England, France, and Spain. Soon, military outposts were established in the area. Later, American traders, explorers, and troops came to the frontier. They were followed by cattle ranchers, who grazed their cattle on the open prairies of the region. Finally, the pioneer farmers arrived on the frontier.

The first pioneer farmers made clearings for small farms. After several years, many of these settlers sought new opportunities on cheaper lands farther west. Their places were taken by pioneers who developed larger farms and built permanent communities. Soon the growing settlements attracted blacksmiths and other craftworkers, merchants, millers, doctors, and teachers.

Crossing the Appalachians. The first pioneers crossed the Appalachian Mountains along steep, narrow trails originally opened by Indians and later used by white explorers and traders. In time, the trails became wide enough for wagons. Boats carried pioneers on the rivers.

The pioneers followed several main routes on their way west. One route went through Cumberland Gap, a natural pass in the Appalachian Mountains near the meeting point of Kentucky, Tennessee, and Virginia. In

Colored wood engraving (1867) by an unknown artist; Granger Collection

A family camps on the trail, *left.* The pioneers could travel only a short distance each day. Most trips across the Appalachian Mountains took several weeks. In the West, the journey from Independence, Mo., to the Oregon or California region lasted four to six months.

Trails of the pioneers during the two big westward migrations are shown on the map above. The eastern region was settled by the pioneers during the first migration, in the late 1700's and early 1800's. The second migration, in the western region, began in the 1840's. The state boundaries on the map are shown as they exist today.

1775, a band of woodsmen led by Daniel Boone cut the Wilderness Road through the gap. Another route followed river valleys through Pennsylvania to Pittsburgh. There, many pioneers boarded river craft and floated down the Ohio.

In 1811, work began on a road that would eventually run between Cumberland, Md., and Vandalia, Ill. It became known as the National Road or the Cumberland Road. Many pioneers from New England traveled west on the Mohawk Trail across New York. Then they followed the southern shores of the Great Lakes. The Erie Canal became an important water route after its completion in 1825.

How the pioneers traveled. Most pioneer families joined several others who were making the same journey west. Some pioneers set off on foot, carrying only a rifle, ax, and a few supplies. However, most pioneer families had one or two pack animals and a wagon or a cart. Some took along a cow to provide milk and to carry a load of goods. Some had chickens, hogs, and sheep. Dogs herded sheep and helped hunt game.

The settlers could not take all their belongings with them when they traveled to the frontier. The two items that were essential for survival were a rifle and an ax. The rifle was needed for shooting game and for protec tion. The ax was used to cut logs for a raft or a shelter to clear land for a farm.

Any bulky tool or household utensil that could be made on the frontier was left behind. Most pioneers took along a knife, an axlike tool known as an *adz,* a to called an *auger* for boring holes, a hammer, a saw, a hoe, and a plowshare. Household goods consisted of a few pots and pans, an iron kettle, and perhaps a spinning wheel. Families made room for essential clothing blankets, and such prized possessions as a clock and family Bible. They also brought along seed for planting their first crops on the frontier.

The pioneers hunted and fished for food on their journey. They also carried some corn meal, salt pork, and dried beef. *Johnnycake,* a kind of corn bread, was favorite food because it did not spoil on the long trip.

The pioneers could travel only a short distance each day, and most trips across the mountains took several weeks. Later, after roads had been built, the *Conestog*

Oil painting on linen (between 1869 and 1890) by Carl Christensen; Private collection (Granger Collection)

Temporary shelters made of a framework of poles covered with branches and mud housed pioneers when they first arrived at a settlement, *left.* Settlers built permanent dwellings when they had more time to spare after planting their first crops.

agon became the favorite vehicle for travel. Conesto-
is had broad-rimmed wheels, sloping sides that were
gher than the middle, and a rounded, white canvas
of. They were pulled by horses, oxen, or mules. The
onestoga was named for the Pennsylvania valley where
was first built. See **Conestoga wagon.**

A barge known as a *flatboat* was commonly used for
er traffic. Early flatboats could carry one family, a
agon, and several horses or other livestock. Later flat-
oats were large enough to transport several families
th all their supplies and livestock. These boats had a
oxlike house in their center. The house became a float-
g fort in case of attack by Indians or river pirates.
me of the pioneers ended their journey by settling
ar the river. They took apart the house and flatboat
d used the lumber to build shelters ashore. Other
es of river craft included simple rafts; canoes; narrow
rges called *keelboats;* and, after 1811, steamboats.

How the pioneers obtained land depended on
here and when they settled. During the early settle-
ent of Kentucky and Tennessee, for example, pioneers
nply located and staked out the lands they wanted.
on land companies and wealthy individuals called
d speculators began to claim huge pieces of land.
ese groups and individuals bought land or received
nership from colonial governments or by royal de-
e. They divided the land into smaller homesites and
n resold it to the settlers for a profit.

Land speculators sometimes acquired land from the
lians in the region. In many cases, however, the Indi-
s believed they were granting only the right to use the
d, not the right to possess it. Furthermore, Indian
ds belonged to the tribe as a whole. A group of indi-
uals, even if they were chiefs, did not have the right
sell the lands. These misunderstandings were among
causes of conflict between whites and Indians.

law called the Ordinance of 1785 provided for the
ision and sale of land north of the Ohio River be-
en the Appalachian Mountains and the Mississippi
River. It stated that land there could not be settled until after the federal government had surveyed it. After the land was surveyed, it was to be sold at government auction to the highest bidder. Speculators and land companies bought most of the land and resold it in smaller plots to settlers.

Many pioneers settled on public land before it had been surveyed. These settlers, who did not have title to the land, were known as *squatters.* In 1841, Congress passed a law that enabled squatters to buy their land under rights of ownership called *squatter's rights.*

Establishing a homestead. When a pioneer family arrived where they intended to settle, they could not spare enough time to build a permanent house right away. Instead, they put up a temporary shelter. A framework of poles covered with branches and mud formed the roof and three sides of the shelter. The fourth side was open and faced a fire that burned day and night. During the day, the fire was used to cook food. At night, it warmed the shelter and kept away wild animals.

Most pioneers arrived at a settlement in spring, the planting season. A spring arrival gave them time to clear the land and grow crops for the next winter. Pioneers used axes to cut away the brush, chop down trees, and trim logs. Neighbors lent a hand removing rocks and stumps. Every member of the family helped with the work of starting life on the frontier.

A pioneer settlement

The log cabin was the typical pioneer home in Kentucky, Tennessee, and many other wooded regions. The pioneers cut trees into logs and then chopped notches close to the ends. The notches held the logs to each other when they were fitted together to form the sides of the cabin.

Most log cabins were about 16 feet (4.9 meters) wide and 20 feet (6 meters) long. The sides of a cabin were about 7 feet (2.1 meters) high. The logs were too heavy for one person to lift, and so neighbors gathered to help

The log cabin was the typical pioneer home in regions where wood was plentiful. The settlers cut trees into lo that were fitted together to form the sides of the cabin. The roof consisted of logs covered by *clapboards* (thin boards). The cabin shown at the left does not yet have a complete roof.

Detail of a lithograph by Currier and Ives; Bettmann Archive

one another. The job was called a *house-raising.* After the logs were in place, the spaces between them were plugged with moss, clay, or mud. Filling the spaces was called *chinking.*

Roofing began after the cabin walls had been completed. First the pioneers fitted logs together on top of the walls to form the frame of the roof. Then they fastened *clapboards* (thin boards) to the frame. They overlapped the clapboards so that rain would run off. Few of the early pioneers had building nails. They used wooden pins to hold the parts of the roof together.

The ground served as the cabin floor until the family found time to make a wooden floor. Pioneers split logs lengthwise into long slabs called *puncheons.* Then the pushed them into the earth, split side up, and wedged them together. A puncheon floor was smoother and warmer than the ground, and it improved the looks of the cabin.

A fireplace stood at one end of the cabin. Most fireplaces had a log chimney that was lined with a thick layer of clay or mud to keep it from catching fire. Some had stone chimneys. The family kept a fire burning in the fireplace most of the time for cooking and to provide warmth and some light.

Conner Prairie

Preparing a family meal sometimes included peelin and cutting up apples for a tasty apple pie, *left.* This pho tograph and the ones on the following pages were taken historic villages that re-crea pioneer life.

Some frontier cabins had no windows, and others ıd only small ones. Pioneers covered windows with ıutters or with greased paper, which let in light. Glass ter replaced these window coverings when shopkeep- s brought it from the East.

The cabin door was made of thick pieces of wood fas- ned to crosspieces. The door swung on wooden nges. A deerskin string was tied to the latch and hung ıtside. When someone pulled the latchstring, it drew) the latch and the door opened. At night, the latch- ring hung inside, and the family put strong bars across e door to hold it shut.

Furniture and household utensils. A family started e on the frontier with a few pieces of handmade furni- re and some household utensils. After getting settled, e pioneers bought other items from a peddler or a ɔntier store. Every growing settlement had a black- nith, a cabinetmaker, and other craftworkers.

The family's table was made of several split log slabs ıd sturdy legs. Benches and stools were made of naller slabs. A pole stuck into a wall formed the out- de rail of the bedstead. A notched post held up the ɘe end of the pole. Cross poles laid from the pole to a de wall held a mattress stuffed with dried moss, grass, straw. Quilts, blankets, or animal skins served as bed- ıvers. Many pioneers had no beds. They rolled up in ɘar or buffalo skins and slept on the floor. Some cabins ıd a loft where the children slept.

Pioneers made many of their household utensils. They rved wooden spoons, ladles, bowls, and platters. They so whittled long pegs that were driven into cabin walls hold the family's clothing. Deer antlers, hung over the ɔor or fireplace, made a good rack for the pioneer's le, bullet pouch, and powder horn. Gourds served as ıps and containers. Candles provided light.

Food. Corn and meat were the basic foods of a pio- ɘer family. The family ate corn in some form at almost ery meal. The pioneers grew corn as their chief crop r several reasons. It thrived even in uncultivated soil, pt well in any season, and could be used in many

Conner Prairie

A blacksmith was an important member of many pioneer communities. Blacksmiths shaped tools and other iron products in their workshops and then sold these goods to the settlers.

ways. The pioneers ground corn into meal. They used the meal to make mush or various kinds of corn bread—ashcake, hoecake, johnnycake, or corn pone. They also made a dish called *hominy* by softening whole, dried corn in lye or water to remove the hull. For a special treat, families roasted ears of corn. The pioneers also used corn as feed for their animals.

The pioneers raised cattle, hogs, sheep, and chickens. They also hunted wild fowl and other game for much of their meat supply. Many meals consisted of wild duck, pigeon, or turkey, or bear, buffalo, deer, opossum, rabbit, or squirrel. Fish were abundant in lakes and streams.

The pioneers had no refrigeration, but they knew how to keep meat from spoiling. They cut some kinds of meat into strips that they dried in the sun or smoked over a fire. Some meat, especially pork, kept well after being salted or soaked in *brine* (salty water).

Salt was in great demand on the frontier for preserving and seasoning food. It brought a high price when traders from the East sold it by the barrel. Rather than

Conner Prairie

A cabinetmaker provided settlers with finely crafted furniture and other wooden products. Before a cabinetmaker arrived at a settlement, pioneers made their own furniture and such household utensils as wooden spoons and bowls.

Living History Farms

Cornhusking was one of the first steps involved in preparing corn meal. Pioneer families used the ground meal to make mush and various kinds of corn bread. Corn was a basic food of the pioneers, and they ate it in some form at almost every meal.

Living History Farms

Chopping wood for a fire required a strong hand and a sturdy ax. An ax and a rifle were the two items that pioneers considered essential for survival on the frontier.

Conner Prairie

Carrying fresh water from a well, stream, or other source was backbreaking labor. Members of a pioneer family shared the tasks that needed to be done around a homestead.

pay the high price, some settlers banded together once a year and traveled to a *salt lick.* Salt formed naturally on the ground at some salt licks. Salt springs bubbled up out of the ground at others. At a salt lick, settlers could gather salt or boil their meat in the salty water. Wild animals also came to licks for the salt, and so pioneers often found good hunting there.

The pioneers grew vegetables and herbs for their own use and occasionally to trade with a local shopkeeper for other goods. Most of the vegetables planted by the settlers—beans, cabbages, potatoes, pumpkins, squash, and turnips—could be cooked into hearty meals. Herbs used by the pioneers included garlic, parsley, rosemary, sage, and thyme.

Families that owned a cow often had milk with their meals. Coffee and tea were too expensive for most frontier families except on rare occasions. Whiskey made from corn was a common drink. The pioneers sometimes mixed corn whiskey with water, added some sweetener, and served it to the entire family. Common sweeteners included honey, molasses, and maple sugar or maple syrup.

Clothing. For their first year or two on the frontier, most pioneers wore the clothes they had brought with them. After this clothing wore out, they made their own. Fabrics were expensive, and making clothes was a long and difficult process. Pioneer women generally took responsibility for making clothes. They spun linen yarn from flax and wool yarn from the fleece of sheep. They then wove the yarn into cloth, which they used in making shirts, trousers, dresses, and shawls.

Many frontiersmen wore a hunting shirt made of deerskin or *linsey-woolsey,* a coarse homemade cloth of linen and wool. The shirt fitted loosely and hung to the thighs. It had no buttons and was held in place at the waist by a belt. Instead of a collar, the shirt had a cape, sometimes trimmed with fringe. Frontiersmen wore deerskin trousers. Deerskin became cold and stiff when wet and felt uncomfortable next to the skin. A man in deerskin usually wore underclothes of linsey-woolsey.

Linsey-woolsey was also commonly used to make

Conner Prairie

laking clothes was generally the responsibility of pioneer 'omen. They spun yarn and then wove it into cloth, *above.* They ›ed the cloth to make shirts, trousers, dresses, and shawls.

othing for women and children. Most pioneer women 'ore a petticoat and a dress that resembled a smock. 'he petticoat was worn as a skirt, rather than as an un-ergarment. In cold weather, women wore a shawl of 'ool or linsey-woolsey. Children wore the same kind of lothing as their parents.

The pioneers wore the shoes that they had brought 'ith them for as long as they could. They went barefoot 'henever possible to extend the life of their shoes. Vhen their shoes finally wore out, the pioneers bought ew ones from a local merchant or bartered furs or ther goods for shoes. In the early stages of frontier life, ɔme settlers made moccasins or *shoepacks* of hide. hoepacks resembled moccasins, but they covered the nkles and had sturdy soles. For warmth and comfort, ıe pioneers stuffed their moccasins or shoepacks with eer hair or leaves.

In summer, the women and girls wore sunbonnets rge enough to shield the face and neck. In winter, they 'ore woolen bonnets or covered their heads with ıawls. Men and boys wore coonskin caps or fur hats in ɔld weather. In summer, they put on hats made of ›osely woven straw or cornhusks.

Tools. Pioneers started farming with the hoe, plowshare, and other tools that they brought with them. The cabin soon became a workshop as well as a home. The pioneers made most of their own farm tools, including harrows and rakes, which were used to break plowed earth into finer pieces and smooth the soil.

A number of tools and techniques were involved in making corn meal. First, the pioneers pulled off the cornhusks. In most cases, they then *shelled* the corn—that is, they removed the kernels from the ear. Some pioneers separated the kernels from the cob by hand. Others used a homemade threshing tool called a *flail* or another implement.

The pioneers made several kinds of mills to grind the kernels into meal. Some made a hand mill called a *quern.* This mill consisted of two large, flat stones, one on top of the other. The top stone had a wooden handle attached to it and a hole through the center. Kernels were placed in the hole. When the handle was turned, the corn was ground into meal between the stones. Another type of mill consisted of a heavy log and a hollowed tree stump. Corn was put into the hollow and pounded into meal with the log. Some pioneers simply grated the corn into a coarse meal. They made a grater by punching holes in a sheet of iron and fastening it to a block of wood. A husked ear of corn was rubbed against the sharp, raised edges of the holes in the metal.

The pioneers usually molded their own bullets from lumps of lead sold by the settlement storekeeper, who also sold gunpowder. They obtained iron tools from a blacksmith. Pioneers often used corn or corn meal instead of money to buy supplies. If a settlement had no store, a few settlers traveled together to the nearest town or trading post to buy what they needed.

Health. One of the greatest dangers to the pioneers was disease. Epidemics on the frontier killed large numbers of people, especially children and older people. The most feared disease was smallpox. Many communities suffered outbreaks of cholera, malaria, and yellow fever. Such childhood diseases as whooping cough, diphtheria, and scarlet fever were common.

The settlers also suffered from colds and other minor illnesses. Nearly everyone was affected at one time or another by a malarial fever called *ague.* Accidents resulting in cuts, bruises, sprains, and broken bones occurred frequently. Childbirth was dangerous. Pioneer women bore children without the benefit of proper medical care. Many women died in childbirth, and many children died at birth or as babies.

There were few doctors on the frontier. The main responsibility for caring for the sick fell upon the pioneer women. They relied on a combination of home remedies and folk cures to treat illnesses. For example, one cure for colds and sore throats involved tying a piece of fat meat with pepper around the neck of the sufferer. Wearing a bag of *asafetida,* an herb that smells like garlic, around the neck was said to keep a person healthy. Some diseases were treated by *bloodletting*—that is, having some blood removed from patients. Bloodletting, also called *bleeding,* was believed to remove "bad blood" and fever from the sick. This procedure was typically carried out by a doctor, *apothecary* (pharmacist), or barber.

Indian cures were also popular among the pioneers.

Bettmann Archive

A settlement school had few books and no chalkboards, charts, or maps. The children sat at long wooden benches or crude desks and repeated lessons given by the teacher. Most teachers had little, if any, formal training.

Such treatments often involved the use of plants, herbs, and the bark of trees. For instance, a brew of boneset tea was used to treat colds. Chewing prickly-ash bark eased toothaches. Sassafras and goldenseal helped relieve stomach ailments.

Education. At first, education on the frontier was informal. Parents who could read taught children some lessons from the Bible and other books that they brought with them from the East. Soon, frontier communities set up formal schools. Most schools had only one room and were built by the settlers. The pupils sat at long wooden benches or crude desks.

Teachers were scarce. Many did not stay long in a particular area, and others left the profession after only a few years. In many cases, a teacher was *boarded around* in payment for services. The teacher lived for a few months with one family and then with another, receiving food and lodging. Some communities paid their teacher a small salary. Most teachers had little, if any, formal training.

A settlement school had few books and no chalkboards, charts, or maps. The children learned by repeating lessons read by the teacher. The teacher taught them reading, writing, and arithmetic. Famous textbooks included the readers of William H. McGuffey and the spelling books of Noah Webster. Spelling bees were both a part of the school curriculum and a popular form of recreation. Adults and children alike competed for the honor of being the best speller in the community.

Students wrote on wooden boards and used pieces of charcoal as pencils. Some had pens made of goose quills and ink made from bark or berries. Slates came into use about 1820. Most children attended school only during the winter. At other times, they were needed at home to help with the farm and household tasks.

Religion was an important part of pioneer life. Most settlers were Christians, and almost every large pioneer settlement had a church. In small settlements, services were held in family homes. Parents taught prayers and hymns to their children and tried to keep Sunday as a day of rest and worship.

A traveling preacher visited many settlements regularly. He conducted church services and funerals and performed marriages and baptisms. The preacher was called a *circuit rider* because he rode horseback from one settlement to another on a route known as a *circuit.*

Sometimes a preacher organized a *camp meeting.* This special outdoor religious service lasted several days and nights and attracted families from many settlements. People brought food and other supplies and camped in a large clearing where the meeting was held. Members of many religious groups attended camp meetings, which often featured several preachers. Methodists typically made up the largest group, but such denominations as Baptists and Presbyterians also took part.

Camp meetings and other religious gatherings served an important social function in addition to a religious role. They were good places to catch up on news or simply gossip. They also enabled single men and women to make friendships that could lead to courtship and marriage.

Government. Early frontier settlements had no formal governmental bodies or law enforcement officials. The community as a whole usually made decisions, settled disputes, and punished troublemakers. Sometimes a special commission consisting of several prominent members of the community was set up to resolve conflicts between individuals.

In 1787, Congress passed the Northwest Ordinance. This law established rules for formal government in the Old Northwest, which then became known as the Northwest Territory. This territory became a model for all territories that later entered the Union as states. The ordinance declared that at first a territorial government would consist of a governor, a secretary, and three judges appointed by Congress. After its adult male population reached 5,000, a territory could elect a legislature and send a nonvoting delegate to Congress. After the population reached 60,000, a territory could write a state constitution and apply for statehood.

Generally, the first action a territorial government took was to organize a local militia. The militia served as

territory's military force. It also supervised elections nd set and collected taxes. In time, officials of the ounty court system took over many functions from the nilitia. These officials included a surveyor, a treasurer, a oroner, a sheriff, a justice of the peace, and a county lerk. They kept law and order, issued licenses, and set ees for local businesses. They also assessed and colected taxes.

Social activities. The pioneers brightened life on the rontier with parties and other get-togethers. They nixed work with fun and sports whenever possible. In iutumn, they held cornhusking contests and nutjathering parties. In spring, they assembled in maple jroves to make sugar and syrup. The women often got ogether for quilting parties. The quilts were much in lemand as bedcovers.

The settlers always enjoyed a house-raising. The men stopped working on the house now and then to run aces or to hold wrestling bouts or shooting contests. After the job was finished, everyone celebrated with a ively feast. The women prepared plenty of food, and after eating, the settlers sat around telling stories. As a ule, someone brought along a fiddle, and dancing and singing went on until late in the night.

A wedding was a special time of fun and celebration. The pioneers liked to play tricks on a couple about to be married. Sometimes the women "kidnapped" the bride while the men rode off with the groom. Of course, both managed to escape in time to be married. During the couple's wedding night, some guests, usually young men and boys, gathered outside the newlyweds' home. There, the assembled group shouted, banged on pans, and otherwise created great noise in a tradition called a *charivari* (pronounced *SHIHV uh REE).*

Pioneers and Indians

Peace and war. During the colonial period, the British Proclamation of 1763 forbade white settlement west of an imaginary line drawn through the Appalachian Mountains. The proclamation was designed to prevent pioneers from moving onto Indian lands, which the Indians were prepared to defend. But many colonists ignored the proclamation, which was not strictly enforced, and settled west of the Appalachians anyway. Treaties negotiated with the Indians in 1768 shifted the proclamation line westward and opened the way for settlement of what are now West Virginia and southwestern Pennsylvania. Some pioneers went as far west as what are now eastern Kentucky and Tennessee.

Beginning with President George Washington, the official policy of the United States toward Indians was generally one of peace through negotiation, trade, and treaties. According to laws passed during the 1790's, only the U.S. government could acquire land from the Native Americans. Trade between white traders and Indians was to be regulated by the government to curb unfair practices. Laws and treaties recognized and guaranteed Indian rights to certain lands.

However, neither the U.S. government nor the Native Americans foresaw the crush of settlers that would be moving west in the early 1800's. The pressure of white settlement was so great that orderly relations between the pioneers and the Indians were difficult to maintain. Many land speculators and settlers ignored the rights that Indians had been guaranteed under treaties. Some whites—including some militias—conducted armed invasions into lands that had been reserved for the Indians. Some Indians raided pioneer settlements.

There were several periods of major fighting between Indians and U.S. troops in the region between the Appalachians and the Mississippi River. A series of conflicts between the Army and the Indians north of the Ohio River, in the Northwest Territory, occurred during the early 1790's. It ended in an Indian defeat in the Battle of Fallen Timbers in 1794.

A second major period of hostility began in the early 1800's. At that time, a Shawnee leader named Tecumseh and his brother Tenskwatawa, known as the Shawnee Prophet, organized an alliance of Indian tribes to raid frontier communities. Tecumseh objected to the pioneer settlement of Indian lands. Many tribes in Tecumseh's alliance joined forces with the British against the United States during the War of 1812. Tecumseh was killed in Canada at the Battle of the Thames River in 1813. The Indian uprising ended shortly after his death. See **Indian wars.**

The early treaties between the United States and the Native Americans guaranteed that the Indians could remain on certain lands. However, as more settlers moved into the area between the Appalachians and the Mississippi River, the Indians were pushed off their land. In 1834, the U.S. government created the Indian Territory, a large Indian reservation west of the Mississippi. The reservation spread across an area that covers what are now Oklahoma and parts of Kansas and Nebraska. By 1840, more than 70,000 Indians from east of the Mississippi River had been forced to move to the Indian Territory. Thousands of Cherokee, Chickasaw, Choctaw, and other Indians died on the journey westward. The Cherokee came to refer to their migration as the Trail of Tears. The name was later applied to the forced removal of other tribes as well.

Defending a settlement. Most settlers were never attacked by Indians, but they lived in constant fear of Indians nevertheless. Everyone kept careful watch for Indians and warned their nearest neighbors at the first sign of danger. Messengers spread the alarm throughout the settlement.

A fort called a *stockade* or *station* was the main defense of a frontier settlement. A typical stockade was rectangular, with walls of sharply pointed logs at least 10 feet (3 meters) high. Small sheds or cabins provided living quarters in the stockade. In at least one of the corners of the fort stood a *blockhouse,* a two-story tower built of thick timber. Some stockades had a blockhouse in each corner. A blockhouse held at least 25 people. Members of the local militia stood guard at *firing posts* in blockhouses. Firing posts were narrow slits in a wall, just wide enough to shoot through.

The stockade also sheltered new arrivals at a settlement. Newcomers headed for the stockade, where they learned what to do in case of an alarm. Most new arrivals at an established settlement stayed in the stockade until they began settling on their land.

Crossing the Plains

By the 1830's, the first big westward migration had pushed the frontier to the Mississippi Valley. Pioneers

Detail of *The Oregon Trail* (1869), an oil painting on canvas by Albert Bierstadt; Butler Institute of American Art, Youngstown, Ohio

Oregon-bound pioneers encountered many types of terrain, including rugged mountains and a number of rivers, during their trip. From 1840 to 1860, more than 300,000 people made the long journey to the West.

were rapidly settling the area just west of the Mississippi River that became the states of Arkansas, Missouri, and Iowa. Explorers, missionaries, traders, and fur trappers had gone even farther west and southwest. They told of great forests and fertile valleys in the Oregon region and other lands west of the Rocky Mountains.

The stories of the trailblazers made exciting news for many Midwestern settlers. In the 1840's, some Midwesterners chose to migrate to Oregon in search of more opportunities. So did hundreds of families from the East who had just arrived in the Midwest and were seeking places to settle. The Mormons, fleeing persecution in Illinois because of their religious beliefs, also decided to head westward. In 1847, they began to settle in the valley of the Great Salt Lake in what is now Utah. Some Midwestern blacks hoped to escape discrimination by moving to the West, but they often faced prejudice there as well. After gold was discovered in California in 1848, thousands of fortune seekers joined the westward migration. See **Mormons; Gold rush.**

Routes to the West. The settlers encountered several natural obstacles on their way to the fertile valleys of Oregon or the gold fields of California. First, they had to cross the Great Plains, a vast grassland that runs between Canada in the north and Texas and New Mexico in the south. The rugged Rocky Mountains rose west of the Great Plains, and beyond the mountains lay a stretch of desertlike terrain known as the Great Basin. The weather was also a problem. Heavy rains might wash out a river crossing. A spell of dry weather could lead to a shortage of water to drink, less grass for the cattle to eat along the way, and more dust to choke the travelers.

From 1840 to 1860, more than 300,000 people crossed the plains and mountains of the West. Most were bound for Oregon or California. For the long trip, as many as 200 wagons at a time joined together to form a caravan called a *wagon train.* However, trains of 30 or fewer wagons were more common. Most settlers started from Independence, Mo., and followed a route called the Oregon Trail. Those bound for Oregon took this trail northwest to the Columbia River and from there to the Willamette Valley.

Settlers bound for California split off from the Oregon Trail near Fort Hall, in what is now Idaho. They followed any of several trails southwest to Sacramento, Calif. Some settlers took the Santa Fe Trail from Independence to California. This route took settlers to Santa Fe, in present-day New Mexico. From there, pioneers followed the Old Spanish Trail to Los Angeles.

From 1835 to 1855, more than 10,000 people died while traveling on the Oregon Trail. The chief causes of death were firearms accidents and such diseases as cholera and smallpox. Only 4 percent of the deaths among pioneers on the Oregon Trail resulted from Indian attacks.

The wagon train. A family going from Independence to Oregon or California in the 1840's had to plan on a journey of four to six months. They had to be sure they brought enough supplies for the trip because there were few places where they could buy goods along the way. Often travelers traded such items as food, clothing, and firearms among themselves or purchased them from one another. Several guidebooks provided information on the route the travelers were to take as well as tips on what provisions were needed for the journey.

During most of the trip, the family lived in a canvas-covered wagon pulled by several teams of oxen or mules. The wagon resembled the Conestoga but was smaller and sleeker. It was called a *prairie schooner* because, from a distance, its white top looked like the sails of a ship. Many families painted pictures and slogans on the wagon's canvas covering for decoration. Such markings also made it easier for friends to find each other on the crowded trail.

Some single men traveled on horseback with wagon trains. They herded the livestock or rode alongside the wagons, helping the drivers stay on the trail. A wagon train had a large number of livestock. Some trains included more than 2,000 cattle and up to 10,000 sheep.

Each wagon train elected a leader, called a captain or wagon master. All wagon trains were guided by a scout who knew the route and the best places to camp.

Life on the trail. Almost all westward journeys started in the spring. A spring departure gave the pio-

escriptions of the Western trail

The diaries kept by many pioneers of the 1840's tell mostly of hardships and tragedies on the trail westward. However, not all memories of the journey were sad. Octavius T. Howe, describing the migration of the 1840's, wrote:

> . . . those who crossed the plains, though they lived beyond the age allotted to man, never forgot the ungratified thirst, the intense heat and bitter cold, the craving hunger and utter physical exhaustion of the trail, and the rude crosses which marked the last resting places of loved companions. But there was another side. Neither would they ever forget the level prairie, covered with lush grass and dotted with larkspur, verbena, lupin, and geranium; the glorious sunrise in the mountains; the campfire of buffalo chips at night, the last pipe before bedtime and the pure, sweet air of the desert. True they had suffered, but the satisfaction of deeds accomplished and difficulties overcome more than compensated and made the overland passage a thing never to be forgotten and a lifelong pleasure in remembrance.

From *Argonauts of '49*, courtesy of Harvard University Press

The circle formed by pioneer wagons at night became a famous symbol of life on the trail. Probably the best description of such a circle was written by Jesse Applegate, one of the leaders of a wagon train bound for Oregon. In *A Day with the Cow Column in 1843,* he wrote:

> . . . the sun is now getting low in the west, and at length the painstaking pilot is standing ready to conduct the train in the circle which he has previously measured and marked out, which is to form the invariable fortification for the night. The leading wagons follow him so nearly round the circle, that but a wagon length separates them. Each wagon follows in its track, the rear closing on the front, until its tongue and ox chains will perfectly reach from one to the other, and so accurate the measurement and perfect the practice, that the hindmost wagon of the train always precisely closes the gateway. . . . Within ten minutes from the time the leading wagon halted, the barricade is formed, the teams unyoked and driven out to pasture . . .

The cost of heading for California

Several guidebooks provided information on the routes travelers were to take to the West as well as tips on what provisions were needed. The costs of a westward journey varied, depending on the final destination, whether the wagon was to be pulled by mule or oxen, and other factors. Many guidebooks, therefore, offered several estimates of the cost of a trip to the West. The table below gives an estimate for a one-year journey by three people to California in a wagon pulled by oxen. It is based on a table in *The Emigrant Guide to California* by Joseph Ware. This guidebook was published in 1849, one year after gold was discovered in California. The inclusion of mining tools in the list of provisions suggests this estimate was aimed at fortune seekers headed for the California gold fields.

Item	Quantity	Cost
Four yoke of oxen	at $50	$200.00
One wagon cover, etc.		$100.00
Three rifles	at $20	$60.00
Three pair pistols	at $15	$45.00
Five barrels flour	1,080 lbs.	$20.00
Bacon	600 lbs.	$30.00
Coffee	100 lbs.	$8.00
Tea	5 lbs.	$2.75
Sugar	150 lbs.	$7.00
Rice	75 lbs.	$3.75
Fruit, dried	50 lbs.	$3.00
Salt, pepper, etc.	50 lbs.	$3.00
Saleratus (baking soda)	10 lbs.	$1.00
Lead	30 lbs.	$1.20
Powder	25 lbs.	$5.50
Tools, etc.	25 lbs.	$7.50
Mining tools	36 lbs.	$12.00
Tent	30 lbs.	$5.00
Bedding	45 lbs.	$22.50
Cooking utensils	30 lbs.	$4.00
Lard	50 lbs.	$2.50
Private baggage	150 lbs.	
Matches		$1.00
One mule		$50.00
Candles and soap	50 lbs.	$5.30
Total	2,583 lbs.	$600.00

Cost to one person: $200

neers time to get through the western mountains before snow blocked the passes. It also helped ensure adequate grass for the livestock. Most wagon trains could travel about 12 to 20 miles (19 to 32 kilometers) a day. They stopped for a day or two at such Wyoming outposts as Fort Laramie or Fort Bridger to repair equipment and buy supplies. If the oxen hauling the wagons became exhausted, they were shot or simply left to die where they fell. Some were eaten for their meat. In most cases, they were replaced by other animals that had been herded behind the wagon train.

A day on the trail began shortly before dawn. After the travelers rounded up their livestock, hitched their teams to the wagons, and ate breakfast, the train started out. About midday, it stopped for a break known as *nooning.* This break gave both the pioneers and the livestock a chance to eat and to rest. Afterward, the train pressed on to the place where the travelers would camp for the night. When the train arrived at the campsite, the wagons formed a circle for protection against wild animals and possible Indian attacks. In the evening before bed, the pioneers gathered around campfires in the circle to eat and chat. Sometimes, if someone had a fiddle, they sang and danced. Usually, however, they were so exhausted by their day on the trail that they went to sleep as early as possible.

Indians on the Plains. The Oregon Trail crossed lands that the U.S. government had guaranteed to the Indians. The route ran through Indian hunting grounds. Fighting occasionally broke out between the pioneers and the Indians, who opposed this intrusion on their territory. However, most wagon trains had a peaceful journey along the trail. Some tribes guided the early pioneers or helped them at difficult river crossings. The Indians supplied some wagon trains with vegetables and buffalo meat in exchange for tobacco, whiskey, or pieces of iron. During the late 1850's and early 1860's, farmers and cattle ranchers began to settle on the Great

Plains. At that time, fighting became more common as tribes sought to defend their territory. Jerome O. Steffen

Pipe is probably the oldest of musical instruments. Pipes are the ancestors of the present pipe organ and all other wind instruments. According to Greek mythology the god Pan invented pipes (see **Pan**). Prehistoric people fashioned bones into primitive pipes.

The flute is a pipe of the *whistle* type. In this musical instrument, air blown against a sharp edge sets in motion the air in a hollow tube. The oboe and clarinet are *reed pipes.* In these musical instruments, the movements of a thin piece of wood or other material set the air in motion. The trumpet operates on the principle of setting the air in motion through vibrations of the player's lips. André P. Larson

See also **Organ; Clarinet; Flute; Trumpet.**

Pipe is a tube used to transport liquids and gases from one place to another. Pipelines compare in importance with highways and railroads as a means of transporting materials useful to people. Huge pipes bring water to the city from wells, lakes, or other sources of supply. A vast network of pipes then distributes the water to homes, and to each sink, toilet, and other water fixtures in the house. Another network of pipes carries the wastewater away from these fixtures through drains and sewer pipes (see **Sewage**). Long pipelines buried in the ground transport and distribute natural gas in the United States and Canada in the same way water is distributed (see **Pipeline**). Similar pipelines transport crude oil from wells to refineries.

The walls, floors, and basements of modern office buildings and hotels have a maze of pipes. The pipes

arry hot and cold water for general use, steam for heat-ng, and refrigerants for air conditioning. Chemical fac-ries, refineries, and similar industries depend almost ntirely on pipes to move their products about within e manufacturing plant. Warships often have such a aze of pipes that sailors on the ships find it difficult to ove about.

Pipes also serve other purposes than to carry fluids. neumatic pipes transport containers carrying mes-ages. Much of our electrical and telephone wiring runs rough pipes known as conduits, which protect the ires from water and breakage.

Kinds of pipe. Most water pipe larger than 3 inches centimeters) in diameter is made of cast iron, rein-rced concrete, steel, or a mixture of asbestos and ce-ent. Smaller water pipes in buildings may be made of alvanized steel, copper, wrought iron, or a vinyl plastic alled *polyvinyl chloride* (PVC). Gas and oil pipelines are uilt of steel pipe. Cast iron, glazed tile, and concrete re among the materials used for drain and sewer pipe. rigation systems may have lightweight aluminum or VC pipe that can be easily moved. Atomic-power plants ave stainless steel piping. Pipe may be made in several ays, depending on the material and type of pipe de-ired. These ways include molding, casting, welding, nd drawing or pushing the material over a sharp point o make a center hole.

History. People made pipe of clay thousands of years go to carry water. The Romans used lead pipe to con-ect their public fountains to aqueducts. American pio-eers made water systems from logs with holes bored hrough their centers. Later, they made pipes from oops and wooden staves in much the same way bar-els are made. Bobby E. Price

Pipe is a device used for smoking tobacco. People have moked tobacco in pipes for more than 2,000 years. To-acco pipes were brought to Europe during the 1500's y explorers who learned about them from American In-ians. The Indians smoked tobacco during religious cer-monies. The Indians also used the pipe as a symbol of eace.

Pipes consist of two main parts—a bowl and a hollow stem. The bowl holds tobacco, and the stem is connect-ed to the bowl. Smoke from the burning tobacco is drawn into the mouth through the stem. Pipestems are made of plastic, hard rubber, or bone. The most com-mon materials used for bowls are brier (also spelled *bri-ar*), clay, meerschaum, and porcelain. In the United States, some pipes are made of corncobs.

Most pipes are named for the type of material used for the bowl. For example, a brier pipe has a bowl made from the hard wood that comes from the root of the brier shrub. This plant grows in such warm, dry coun-tries as Greece, Italy, and Spain. Most brier pipes are produced in standard shapes and sizes, as well as a style known as *freehand.* Freehand pipes have unusual shapes. Brier pipes are made both by machine and by hand.

Meerschaum pipes are made from a white, claylike substance that is found underground in countries near the Mediterranean Sea. Although meerschaum is frag-ile, it can be carved easily. Meerschaum pipes are craft-ed into beautiful designs, figures, or scenes. The bowls range in length from about 1 inch to 2 feet (2.5 centime-ters to 60 centimeters). Meerschaum changes to a rich brown color after being smoked for some time.

Iwan Ries & Co. (WORLD BOOK photo)

Pipes come in a variety of shapes and sizes and are made from such materials as brier, meerschaum, and porcelain. In the United States, some pipes are also formed from corncobs.

Porcelain pipes are popular in Europe. Many have hand-painted scenes on the bowls, and cherrywood stems. In the Middle East, the *hookah,* or *water pipe,* is popular. The hookah consists of a bowl connected to a vase of water, and a long flexible stem. Before the smoke enters the smoker's mouth, it passes through the water to cool.

People have been collecting smoking pipes for hun-dreds of years, and there are pipe collector clubs throughout the world. Members of these clubs meet to buy, sell, and trade old and new pipes. C. Bruce Spencer

Pipe organ. See **Organ** (Pipe organs).

Pipe Spring National Monument is in northwest-ern Arizona on the Kaibab Indian reservation. A memori-al to Western pioneer life, it has a historic fort and other structures built by Mormon pioneers. It was established in 1923. For area, see **National Park System** (table: Na-tional monuments).

Pipefish gets its name from its long, slim body, which looks like a tube or pipe. The pipefishes form a group of about 230 species of fishes. Most of them live in temper-ate and warm seas. A few species live in fresh water. Pipefishes are relatives of the seahorse. The body of a pipefish is covered with bony plates. Certain kinds of pipefishes may grow 24 inches (61 centimeters) long. The long snout ends in a small, narrow, toothless mouth.

Male pipefishes have an unusual pouch on the abdo-men in which they carry the eggs. The female fish places the eggs in this pouch, where they hatch. The young

pipefishes remain in the pouch until they can care for themselves and are able to leave. John E. McCosker

Scientific classification. The pipefish belongs to the family Syngnathidae.

Pipeline is a system of pipes that transports certain substances over long distances. Pipelines play an important role in the operation and the economy of modern communities. They carry most of the water used in homes, businesses, and industry, and transport natural gas, petroleum, and such petroleum products as gasoline, kerosene, and diesel fuel. They also carry industrial waste and sewage, and particles of coal, iron ore, and limestone used for industrial purposes.

Many pipelines consist of a series of steel pipes welded together. But many gas and water pipelines are made of such plastics as polyethylene and polyvinyl chloride. Pipelines are also made of aluminum, concrete, iron, or a combination of asbestos and cement. Water pipelines are often built in segments connected at joints with watertight gaskets or sealing materials.

A pipeline may be more than 3,000 miles (4,800 kilometers) long. Pipelines range in diameter from about $\frac{1}{2}$ inch (1.3 centimeters) to 15 feet (4.6 meters). Most pipelines are buried at least 2 feet (0.6 meter) underground. Some are laid on the ground or along supports above the ground. Some lines are laid underwater. Pipelines run across deserts, over mountains, and under rivers and lakes.

Pipelines are among the most efficient means of transportation. They deliver large quantities of materials in a continuous flow directly from a supplier to a user. A pipeline 650 miles (1,050 kilometers) long and 40 inches (102 centimeters) in diameter can transport about a million barrels of petroleum a day. Although pipelines are expensive to build, they are relatively cheap to operate and maintain. They distribute more fuels used as energy—chiefly petroleum, petroleum products, and natural gas—than do any other means of transportation.

In the United States, about 227,000 miles (365,000 kilometers) of pipelines carry crude oil and petroleum products to refineries and market areas. Natural gas travels to processing plants and communities through a network of nearly 2 million miles (3,200,000 kilometers) of pipelines. Canada has about 21,000 miles (33,800 kilometers) of petroleum pipelines and approximately 88,000 miles (142,000 kilometers) of pipelines that carry natural gas.

Kinds of pipelines

There are three chief kinds of pipelines: (1) gas pipelines, (2) liquid pipelines, and (3) solids pipelines.

Gas pipelines carry mainly natural gas. Pipes called *gathering lines* transport gas from a well to processing plants. The processed gas is then fed into *transmission pipelines,* which carry it to cities and towns. There, it flows to consumers through *distribution lines.* There are two kinds of distribution lines, *mains* and *individual service lines.* Mains are pipes connected to transmission pipelines. They typically range in diameter from 2 to 24 inches (5 to 61 centimeters). Service lines branch off the mains, and most are 2 inches (5 centimeters) or less in diameter. They carry the fuel sold by utility companies to homes, offices, factories, and other consumers.

Liquid pipelines carry chiefly petroleum, petroleum products, and water. In transporting petroleum, gathering lines take the oil from the well to *trunk pipelines.* Some trunk lines move the oil directly to refineries. Others take it to shipping points for delivery to refineries by tankers, barges, railroad cars, or trucks. The refineries use the petroleum in making gasoline, lubricating oil,

Joel W. Rogers, Earth Images

The Trans-Alaska Pipeline stretches about 800 miles (1,300 kilometers) and taps the oil reserves of Alaska's North Slope. About half the line runs along supports aboveground.

;d other products, which are carried to market areas 1 ough *product pipelines.*

Water-transmission pipelines bring water to cities and 1vns from lakes, reservoirs, wells, and other sources. e water then flows into distribution pipelines, 1 ough mains, and into service lines that lead to build- gs in the community. Pipes inside each building dis- bute the water to faucets, toilets, and other plumbing tures. Another network of pipes carries wastewater ,d sewage from these fixtures through drains and sew- s. Water pipelines also supply water for agricultural d industrial uses, such as in irrigation systems and ning operations.

Solids pipelines transport most materials in the form *slurries,* which are mixtures of liquids and finely ound solid particles. Slurries include coal and water, n ore and water, limestone and water, and coal and l. They flow like liquids, and pipelines that carry slur- s resemble liquid pipelines. Solids pipelines trans- rt certain materials, such as sawdust and wheat, by eans of air flowing through the system.

How pipelines work

Pipelines use tremendous pressure to transport the bstances being carried through them. This pressure ually ranges from 50 to 2,000 pounds per square inch 4 to 1,379 newtons per square centimeter) at the be- nning of the pipeline. It moves natural gas at about 15 iles (24 kilometers) per hour and liquids and slurries at to 5 miles (3 to 8 kilometers) per hour.

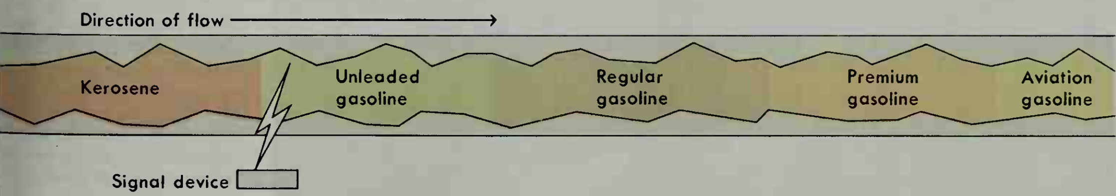
As the substance travels through the line, the pres- ire propelling it decreases because of friction of the aterial against the walls of the pipe. Therefore, the ma- rial requires a boost of energy every 30 to 150 miles 8 to 241 kilometers) to push it along. This energy is pplied by *compressor stations* for gas pipelines and *pumping stations* for liquid and slurry lines. The flow material through a pipeline may also be regulated by ntrol valves along the route.

Several materials at a time can be transported by pelines that carry petroleum products. The different aterials are pumped through the line one after the oth- in "batches" at least 15 to 20 miles (24 to 32 kilometers) ng. The materials are arranged so that the most valu- ble substances are separated from the least valuable. is arrangement reduces any damage that may result if me of the products get mixed together. Near the end f the line, an instrument called a *gravitometer* deter- ines the dividing line between products by measuring e differences in their weights.

Pipelines are continually inspected for leaks and for damage caused by such conditions as corrosion, freezing temperatures, heavy rain, and soil erosion. The locations of underground pipelines are marked to prevent damage from any future construction projects. A coating of tar or some other substance helps protect pipelines against corrosion. Special control devices are installed in pipelines to minimize damage to the environment that may be caused by breaks in the line.

Many people believe that pipelines should not be built in certain areas. Environmentalists fought for years to prevent the construction of the Trans-Alaska Pipeline, which opened in 1977. They argued that the pipeline and the heat of the oil traveling through it could upset the delicate ecological balance of the frozen land. Some conservationists oppose the construction of slurry pipelines in the western United States. They believe the limited water resources of the region are needed for agricultural purposes and should not be used in slurry.

Major pipelines of the world



In the United States, an extensive network of pipelines crisscrosses the country. One of the longest of these pipelines carries natural gas from Baton Rouge, Louisiana, to Pittsburgh, Pennsylvania, Philadelphia, and New York City. It is about 2,000 miles (3,200 kilometers) long and has about 8,000 miles (13,000 kilometers) of branch lines.

The Trans-Alaska Pipeline was built to help reduce the nation's fuel shortage by tapping Alaska's vast oil reserves. The pipeline runs about 800 miles (1,300 kilometers) from Prudhoe Bay on the Arctic Ocean in the north to Valdez on the southern coast of Alaska.

In Canada, about 80 percent of the nation's petroleum and natural gas comes from Alberta. Pipelines move these resources to more heavily populated areas. For example, the Interprovincial Pipeline carries oil about 2,500 miles (4,020 kilometers) from Redwater, Alberta, to Montreal, Quebec. The Trans-Canada Pipeline carries natural gas almost 2,300 miles (3,700 kilometers) from the Alberta-Saskatchewan border to Montreal.

In other countries. The nations of the Middle East rely heavily on pipelines to transport the region's huge production of oil. For example, the Trans-Arabia Pipeline runs about 750 miles (1,200 kilometers) across Saudi Arabia between the Persian Gulf and the Red Sea. The pipeline eliminates the need to use the shipping lanes through the Strait of Hormuz, between Oman and Iran.

One of the world's longest pipelines, the Export Pipeline, delivers natural gas more than 4,000 miles (6,400 kilometers), from western Siberia to Austria, Belgium, France, Germany, Italy, and the Netherlands. Another

WORLD BOOK diagram

petroleum products pipeline carries several products at a time by a process called *continu- us batching.* Various signal devices, such as computers and *gravitometers,* indicate where one roduct ends and another begins. A gravitometer distinguishes between products by their weight.

pipeline, eastern Europe's Friendship Pipeline, transports oil about 2,500 miles (4,000 kilometers) from the Ural Mountains in Russia to the Czech Republic, Germany, Hungary, and Slovakia.

The South European Pipeline carries oil nearly 500 miles (800 kilometers) from Lavéra, France, to Karlsruhe, Germany. In China, the oil fields of Manchuria are linked with Qinhuangdao, a port on the Yellow Sea, by a 715-mile (1,151-kilometer) pipeline.

History

The first pipelines of historical importance made up part of the water distribution system of ancient Rome. This system was more than 380 miles (612 kilometers) long and may have carried up to 320 million gallons (1.2 billion liters) of water daily. It was constructed so that the force of gravity carried the water through the system. In 1582, the first pumps for pipelines were installed in the water system of London.

During the mid-1800's, pipelines started to become an important part of the water distribution system of the United States. The nation's first successful oil pipeline was laid in 1865. It carried about 800 barrels of oil a day from an oil field near Titusville, Pennsylvania, to a railroad 5 miles (8 kilometers) away. The first major natural gas pipeline in the United States was completed in New York in 1872. This line delivered gas from West Bloomfield to Rochester, a distance of about 25 miles (40 kilometers). In 1879, a 110-mile (177-kilometer) oil pipeline began to operate in Pennsylvania. This pipeline carried about 10,000 barrels of oil a day from Coryville, near Bradford, to Williamsport.

The pipeline industry grew rapidly after the development of seamless, electrically welded pipe in the 1920's. This kind of pipe was much stronger than earlier types. It could carry materials under greater pressures and, thus, in larger quantities. It enabled gas and oil companies to build profitable pipelines more than 1,000 miles (1,600 kilometers) long. Today, such lines make up a network that carries oil and natural gas from the major producing areas to every part of the United States.

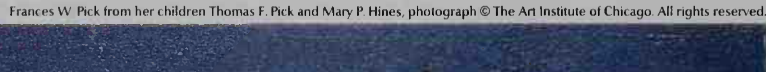
WORLD BOOK illustration by Trevor Boyer, Linden Artists L

The American pipit lives in North America and Asia.



Pipit, *PIHP iht,* is the name of about 35 species of song birds found in most parts of the world. Pipits measure from 5 to 7 inches (13 to 17 centimeters) long. These birds are brownish with dark streaks and white outer ta feathers that show when they fly. Pipits have a character istic graceful walk and a habit of wagging their tail. They feed mainly on insects. Like larks, pipits sing while in flight.

Two species of pipits that live in North America are the *American pipit* and *Sprague's pipit.* The American pipit breeds on *tundras* (treeless plains) of the Far North and on mountaintops in the western part of the United States. It winters in coastal regions of the United States and in Mexico and Central America. It is also found in Asia. Sprague's pipit breeds in short grass prairies from central Canada to the north-central part of the United States, and winters in the Gulf States and Mexico. Both the American pipit and Sprague's pipit build nests of grasses on the ground. The females lay from four to six eggs, which are grayish-white with dark spots.

Martha Hatch Balph

Scientific classification. Pipits belong to the pipit and wagtail family, Motacillidae. The scientific name for the American pipit is *Anthus rubescens.* Sprague's pipit is *Anthus spragueii.*

Pippin, Horace (1888-1946), was an important African American folk painter. Pippin was self-taught as an artist He primarily painted religious themes, war scenes, and

Frances W. Pick from her children Thomas F. Pick and Mary P. Hines, photograph

A Horace Pippin painting shows the blocky, flat forms and rich colors that are typic of the artist's style. This detail of the painting *Cabin in the Cotton* portrays a scene of rural African American life, a common Pippin theme. The oil painting on a wood panel dates from the mid-1930's, ju before Pippin gained nationa recognition as an artist.

ages from African American life. He used rich, often ght colors and painted blocky, flat forms that had no ecific details. Pippin created simple images, and his intings tell easily understood stories.

Pippin was born in West Chester, Pennsylvania, and ew up in Goshen, New York. His grandparents had en slaves. He left school at the age of 14, doing vari s odd jobs to support his ill mother. Pippin was seri sly wounded in the right shoulder while serving in orld War I (1914-1918). The injury left him unable to se his right arm above his shoulder. After the war, he voted himself to painting in West Chester.

Pippin's work first gained recognition in the late 30's, during a revival of interest in American folk art. attracted nationwide attention in 1938, when the Mu um of Modern Art in New York City exhibited four of pictures in a show called "Masters of Popular Paint g." Deborah Leveton

raeus, *py REE uhs* (pop. 179,967), is the third largest y in Greece. Only Athens and Thessaloniki are larger. aeus lies along the Saronic Gulf, 5 miles (8 kilometers) uthwest of Athens (see **Greece** [political map]).

Piraeus has three harbors and is the leading Greek rt. Over half the country's imports and exports pass rough the harbors. Products of Piraeus include alco lic beverages, cement, chemicals, cloth, food prod ts, and metal goods.

Piraeus was an important Greek port in ancient times. the 400's B.C., the Athenians built walls at its harbors d between Piraeus and Athens to protect Athens from vasions. About 450 B.C., the Greek architect Hippoda us created a city plan for Piraeus based on the regular rangement of rectangular city blocks. The plan was e of the great achievements of the Age of Pericles e **Pericles**). In 86 B.C., the Roman general Lucius Cor lius Sulla destroyed the city's harbors. Piraeus then came a small, unimportant village. In A.D. 1834, the eek government restored the harbors, and Piraeus ain grew in size and importance. John J. Baxevanis

irandello, *PIHR uhn DEHL oh,* **Luigi,** *loo EE jee* (1867- 36), an Italian author, won the 1934 Nobel Prize for lit ature. Pirandello is known for his philosophic dramas. e best of his plays argue that reality is unknowable, d that truth varies according to the point of view. He aimed we assume numerous roles or masks in our ily lives, none of them our true self. We should thus wary of passing hasty judgment on others.

Pirandello's best-known play is *Six Characters in earch of an Author* (1921), a fantasy that highlights the p between reality and fiction. *Henry IV* (1922) is a mile one of modern psychological drama that examines the lation between truth and illusion. Pirandello's 1917 ay *Right You Are (If You Think You Are)* is a direct anal is of the relativity of truth. In addition to his 44 plays, randello also published six volumes of poetry and rote more than 300 short stories. The best of his seven vels is probably *The Late Mattia Pascal* (1904).

Pirandello was born in Girgenti (Agrigento), Sicily. He rned a doctorate in philology at the University of onn in Germany in 1891. He married in 1894 and led a ntented life until his wife went insane in 1904. To fi nce her home care, he taught literature at a girls' hool in Rome, enduring his wife's frequent bouts of vi ent jealousy. His turbulent domestic life helped stimulate the emphasis in his dramas on madness, illusion, and the uncertainty of reality. Frederick C. Wilkins

Piranesi, *PEE rah NEH zee,* **Giovanni Battista,** *joh VAHN nee baht TEES tah* (1720-1778), was an Italian printmaker known for his etchings of ancient Roman architecture. His works inspired architects to imitate Roman designs and influenced the neoclassical style in art of the 1700's.

Piranesi's prints of Rome were published in several collections, including more than 200 in *Roman Antiquities* (1756) and 135 in *Views of Rome* (1748-1778). Piranesi often exaggerated the size and grandeur of the ruins in his prints to show his admiration for the Romans. He also used dramatic highlights and dark shadows to create a feeling of mystery, particularly in a series of 16 etchings called *Prisons* (1745, 1760-1761). These pictures show enormous spaces crowded with chains, pulleys, ropes, stone arches, and high staircases. Human figures seem dwarfed and overpowered by the surroundings. Piranesi said he imagined these scenes while he was delirious from a fever. Artists of the Romantic period of the early 1800's admired these dreamlike fantasies.

Piranesi was born in Mogliano, Italy, near Venice. He studied architecture, stage design, drawing, and printmaking as a youth. Elizabeth Broun

Plate VIII from the *Prisons* series; Calcografia dello Stato, Rome (Alinari/Art Resource)

A Piranesi etching from his *Prisons* series shows a dreamlike interior of towering arches and high staircases. The series contrasts with his many detailed scenes of Roman architecture.

Piranha, *pih RAHN yuh,* is a sharp-toothed fish that lives in lakes and rivers throughout most of South America. Piranhas have been described in motion pictures and in legends as vicious, bloodthirsty predators that

can tear a human being to shreds in seconds. In actuality, piranhas rarely have attacked people. However, piranhas can be a serious problem if introduced into other waters, where they will eat large numbers of native fish, amphibians, and other water animals.

There are at least 25 species of piranhas. They have deep bodies that are flattened on the sides. Most piranhas are olive-green to blue-black, with red or orange bellies. The most common species is the *red piranha,* which can grow to nearly 1 foot (30 centimeters) long. All piranhas have razor-sharp teeth that they use to devour a variety of prey. Normally, piranhas swim alone and feed on smaller fish or on seeds or fruit in the water. Occasionally, they swim together in schools. A school of piranhas, like a pack of wild dogs, may attack a much larger animal and bite away pieces of its flesh.

WORLD BOOK illustration by Colin Newman, Linden Artists Ltd.

The piranha has razor-sharp teeth that it uses to attack its prey. Piranhas live in South American rivers and lakes.

Some states prohibit the importation of wild piranhas. However, some fishing enthusiasts value piranhas because the fish are fierce fighters when hooked and are good to eat. Also, some tropical aquarium owners at first enjoy keeping a piranha but later tire of the expense of feeding it. As a result, wild piranhas have been introduced into some rivers and lakes in the United States, particularly in the Southeast. John E. McCosker

See also **Pacu.**

Scientific classification. Piranhas belong to the family Characidae. The red piranha is *Pygocentrus nattereri.*

Pirate is a person who attacks and robs ships. Such robbers have also been called *buccaneers, filibusters, freebooters, ladrones, pickaroons,* and *sea rovers.* Pirates differ from sea raiders known as *privateers.* Pirates were not licensed by any nation, but privateers were licensed by a particular nation during wartime to attack enemy ships. Therefore, privateers were generally not considered pirates.

Pirates have robbed ships and raided coastal towns since ancient times. The greatest period of pirate attacks, or *piracy,* occurred from the 1500's through the 1700's on the Mediterranean and Caribbean seas. The most famous pirates of this age included Henry Morgan, Blackbeard, and William Kidd. Most pirates were men, but a few women became pirates.

Widespread piracy no longer exists. But attacks have occurred in some areas. In the 1980's, for example, pirates carried out numerous attacks against Cambodian and Vietnamese refugees in the Gulf of Thailand.

How pirates lived. People became pirates for various reasons. Sometimes, the harsh conditions of life at sea led honest seamen to desert or mutiny their ships. These men often turned to piracy to survive. Others sought riches or adventure. Many privateers drifted into piracy when wars between nations ended.

Legend, fiction, and motion pictures have helped create an exciting, romantic image of pirates. A typical pirate is portrayed as a fierce-looking man with a beard. He is sometimes handsomely dressed.

In real life, however, most pirates probably led miserable lives. They were often drunk and quarrelsome. Many pirates died of wounds or disease. Some were shot or marooned by their own crews or captured and sentenced to death by authorities.

In spite of their unlawful way of life, most pirate crews developed rules and regulations to govern their ships. Crew members elected a captain and other officers and had a code of punishment for breaking agreements. They also developed pay scales to determine each person's share of the *booty* (stolen goods).

Until about 1700, pirate ships flew a red banner called the *Bloody Flag.* They then began using flags that pictured such objects as skeletons, flaming swords, and hourglasses. The most popular of the new pirate flags showed a white skull and crossbones on a black background. This symbol became known as the *Jolly Roger.*

Ships involved in trade carried weapons in case of attack. But a pirate crew usually outnumbered the other crew and could defeat it in hand-to-hand combat after coming aboard. Pirates seized trading ships by first maneuvering their vessel next to the ship. They boarded by using hooks and ropes to keep the ships together.

Besides robbing ships, pirates also attacked towns. In

WORLD BOOK illustration by David Cunningham

A pirate carried several kinds of weapons, including a pistol, daggers, an ax, and a short, curved sword called a *cutlass.* Most pirates were men.

WORLD BOOK illustrations by David Cunningham

ate flags commonly featured a skull and crossbones. Some o pictured a skeleton, a sword, or an hourglass. The flags at e left are associated with, *top to bottom,* Emanuel Wynne, rtholomew Roberts, and Edward Low. The flags at the right ve not been identified with a particular pirate.

e towns, they murdered innocent people and took isoners. The pirates held some captives for ransom d enslaved others. They sometimes tortured prisoners get information about treasure. There is little evi- nce that they made their victims "walk the plank."

Pirates and privateers of the Mediterranean. uch of the piracy during ancient times occurred along e eastern coast of the Mediterranean Sea. The Roman npire was threatened by pirates who cut off food sup- ies and other imports. In 67 B.C., Roman forces began campaign that rid the area of pirates for some years.

Sea raids flourished on the Mediterranean from the rly 1500's to the early 1800's. But during that period, e raiders were licensed by their governments and ere considered to be privateers, not pirates. This priva- ering resulted partly from a rivalry between Muslims d Christians. Muslim privateers from the Barbary ates, which lay along the coast of northern Africa, amed the Mediterranean and attacked ships of ance, Italy, Spain, and other Christian nations of Eu- pe. These privateers, sometimes called *Barbary cor- irs* or *Barbary pirates,* had bases in Algiers, Tunis, and ipoli. The corsairs also raided coastal towns of West- n Europe. Raids on the Mediterranean continued until ench forces seized the last base in Algiers in 1830. The ost famous corsairs were Occhiali, the brothers Arouj d Khair-ed-Din Barbarossa, and Dragut.

Pirates of the Caribbean and other areas. During e 1500's, competition between Spain and other Euro- an countries to colonize the newly discovered Ameri- s led to an outbreak of piracy on the Caribbean Sea. rates sailed the Caribbean for over 300 years. By 1550, ain controlled the West Indies and large areas of the uth American mainland. As a result, bands of English, Dutch, and French pirates robbed Spain's ships and looted its settlements. Among these robbers were the "sea dogs" sent by Queen Elizabeth I of England to raid Spanish fleets. They included such famous English captains as Sir Francis Drake and Sir John Hawkins. These raiders committed acts of piracy before the queen declared war on Spain and made them privateers.

During the early 1600's, French, English, Dutch, and other European sailors settled on Hispaniola, Tortue Island (also called Tortuga Island), and other Caribbean islands. They raided Spanish ships and towns and soon became known as *buccaneers.* Their numbers grew, and eventually no town was safe along the *Spanish Main,* an area that included the coasts of what are now Colombia and Venezuela. The most famous buccaneer was the Englishman Henry Morgan. In 1671, he led 2,000 other buccaneers in the looting and destruction of Panama City, Panama, the largest Spanish city in Central America. When it suited them, some buccaneers also served as privateers.

During the late 1600's, the buccaneers sought new targets. Some of them carried out raids in Spanish-controlled areas of the Pacific Ocean. About 1690, the buccaneers and other European pirates began attacking the ships of any nation. Some of the pirates sailed to waters near the slave-trading stations of west Africa. Reports of great wealth lured others to the Indian Ocean. Once there, they ambushed ships that carried rich cargoes of silks, spices, jewels, and ivory. Many of these pirates settled among the people of Madagascar, an island that lies east of the African mainland. Perhaps the best known of the pirates associated with Madagascar was the Scotsman William Kidd. Kidd had been sent by England to capture pirates, but instead he became one himself.

European pirates also turned their attention to North America. By 1700, English colonists had established successful trade routes between North America and Europe. A number of pirates set up a base in the Bahamas and attacked many of the ships that followed these routes. The pirates' leaders included Benjamin Hornigold, "Calico Jack" Rackham, and Charles Vane. Pirates who sailed with these men included the women Anne Bonny and Mary Read. But the most notorious pirate of this time was Blackbeard, who used the names Edward Teach and Edward Drummond. Blackbeard terrorized the Carolina and Virginia coasts in 1717 and 1718. A small fleet of ships from Virginia hunted Blackbeard down and killed him in 1718. By the late 1720's, the British Royal Navy had put an end to most of the activities of European pirates throughout the world.

Asian pirates. Beginning in the early 1600's, pirates from countries in Asia attacked European and other trading ships in many Asian waters. For example, Arab pirates operated off India's Malabar Coast, and Malaysian pirates attacked ships in the South China Sea. Pirates from Taiwan and the mainland of China sailed in the waters off China and Japan. By the mid-1800's, however, the navies of Britain and of other countries had cleared the seas of almost all pirates, including those from Asia. Robert C. Ritchie

Pirogue, *puh ROHG,* is either a type of dugout canoe or a modern imitation of that kind of craft. People use pirogues for fishing and transportation in the swamps and bayous of southern Louisiana. The traditional Louisiana pirogue is a flat-bottomed boat made from a log. Today, some pirogues are made of plywood and other materials. The boats may be from 10 to 20 feet (3 to 6 meters) long. They have round, flaring sides and a sharp bow. People propel them with paddles or poles.

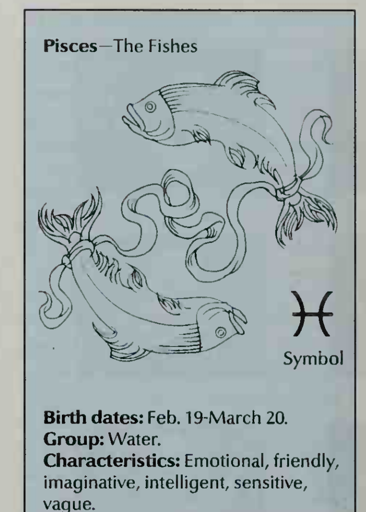
Pacific Islanders once used a pirogue that had a second hull, called an *outrigger,* to prevent the boat from tipping. They used paddles or a triangular sail to propel the boat. Octavia N. Cubbins

Pisa, *PEE zuh* (pop. 98,928), is an old city of Italy famed for its marble bell tower (see **Leaning Tower of Pisa**). The city lies on both banks of the River Arno. For location, see **Italy** (political map). Pisa has a university founded in 1343 and an academy of fine arts established by Napoleon. The town has valuable art treasures. It is also a manufacturing center. The house where the scientist Galileo was born is in Pisa. Anthony James Joes

Pisano, *pee SAH noh,* **Giovanni,** *joh VAHN nee* (1248?-1314?), was an Italian sculptor and architect. His father, Nicola Pisano, was also a sculptor. Together, they combined the styles of French Gothic art and classical Roman art in works that influenced artists of the Italian Renaissance. Giovanni's masterpiece is a hexagonal pulpit (1301) in the Church of Sant' Andrea at Pistoia. The pulpit is decorated with five panels that portray episodes related to the life of Jesus Christ. The panels show the Gothic influence in their dramatic composition and in the emotional character of the action.

Giovanni was probably born in Pisa. He began his career about 1265, working with his father on a pulpit in the Cathedral of Siena. Many art historians believe that Giovanni later designed the cathedral's front, which combines Gothic elements with the earlier Romanesque style. Vernon Hyde Minor

See also **Sculpture** (Italian Renaissance sculpture; picture).



Pisano, *pee SAH noh,* **Nicola,** *nee KAW lah* (1210?-1278?), was an Italian sculptor, as was his son Giovanni. Nicola Pisano's reliefs were created in the classical style that anticipates the art of the Renaissance.

Pisano was probably born in southern Italy and later moved to Pisa. His masterpiece is the six-sided pulpit (1260) in the Baptistery of Pisa. He carved scenes of quiet dignity for the panels, using forms and details borrowed from Roman monuments. In 1268, Pisano finished a large, eight-sided pulpit for the Cathedral of Siena. In this work, Pisano created more dramatic, unified, and action-filled scenes than in his earlier sculptures.

Pisces is ruled by two planets, Jupiter and Neptune. Pisces is a water sign.

According to astrologers, people who are born under the sign of Pisces, from February 19 to March 20, are ruled by their emotions, rather than by reason. Pisceans are talented and have vivid imaginations. However, it is difficult for them to make decisions or to solve practical problems. They often retreat from reality into a world of their own dreams and fantasies.

Pisceans are intelligent and friendly people. They have a keen awareness of other people's moods. Pisceans lack the ability to commit themselves to a long-term course of action. Instead, they frequently drift from one interest or project to another. Christopher McIntosh

Pisgah, Mount. See **Mount Pisgah.**

Pisistratus, *py SIHS truh tuhs* (? -527 B.C.), was a popular ruler of ancient Athens. He employed the poor in such public works programs as building temples and fountains. Pisistratus gained power in 560 B.C., but the Alcmeonid family took control of the city in 556 B.C. Pisistratus went to nearby Macedonia, made a fortune in mining, and formed an army of hired soldiers. His troops took Athens in 546 B.C., and he ruled until his death. Pisistratus encouraged writers and artists. He ordered one of the first collections of Homer's poems to be made. See also **Hipparchus** (ruler); **Library** (Ancient libraries of papyrus). Thomas W. Africa

Pissarro, *pih SAHR oh,* **Camille,** *ka MEE yuh* (1830-1903), was a French Impressionist painter. He was the oldest artist of the Impressionist movement. Pissarro was also probably the most popular and respected member among the Impressionists. He influenced the careers of such artists as Paul Cézanne, Paul Gauguin, and Vincent van Gogh. See **Impressionism.**

Pissarro had a modest disposition, which is reflected in his fondness for painting humble rural scenes and landscapes. His short, patchy brushstrokes give vitality to these commonplace scenes. Pissarro's early paintings emphasize dark tones. He gradually began concentrating on lighter colors, especially after he started to paint

Oil painting on canvas (1870); the Louvre, Paris

Pissarro's paintings typically portray quiet rural scenes. His *Carriage at Louvenciennes* shows the short, patchy brushstrokes he used to paint these subjects. The placement of the figures, house, road, and trees shows how Pissarro carefully organized his compositions.

tdoors in the late 1860's. His pictures show greater ncern with details of rural life and work than those of ost other Impressionists. Pissarro was born on the is- ıd of St. Thomas in the Virgin Islands. Richard Shiff

stachio nut, *pihs TAH shee oh* or *pihs TASH ee oh,* metimes called a *green almond,* is the small seed of e pistachio tree. This tree grows in the eastern Medi- ranean region, in southwestern Asia, and in the uthwestern United States. Growers in California pro- ıce millions of pounds of pistachio nuts each year. A stachio nut may be 1 inch (2.5 centimeters) long. It has smooth, thin, and hard shell that tends to open at the lge. Its thin, smooth husk, or skin, is pale red to yellow. ıe husk is removed before the kernel is processed.

WORLD BOOK illustration by Stuart Lafford, Linden Artists Ltd.

stachio nuts grow in clusters on pistachio trees. The edible een kernel, *right,* has a mild flavor.

The kernel may be eaten as a nut or ground and used as a food flavoring and coloring. The kernel's texture is very fine. Pistachio kernels can be salted while in the shell by placing them in a salty solution. In southwestern Asia and the eastern Mediterranean region, the kernels are pressed for their oil.

The pistachio tree grows well in dry regions. It seldom rises over 30 feet (9 meters) high, but its branches spread widely. Its leaves, which produce a sticky resin, drop off during the winter.

Every pistachio tree is either male or female. In order to produce nuts, the female trees must have a male tree nearby to provide pollen for their flowers.

Richard A. Jaynes

Scientific classification. The pistachio tree is in the cashew family, Anacardiaceae. It is *Pistacia vera.*

Pistil. See **Flower** (The parts of a flower).

Pistol. See **Handgun**.

Piston, *PIHS tuhn,* **Walter** (1894-1976), was a leading American composer. He won the 1948 Pulitzer Prize in music for his Symphony No. 3 (1948) and the 1961 Pulitzer Prize in music for his Symphony No. 7 (1961).

Piston was a member of the neoclassical movement of the early 1900's. His compositions are noted for their skillful orchestrations and expert use of counterpoint (see **Counterpoint**). In addition to eight symphonies, Piston primarily wrote concertos and other works for orchestra as well as many compositions for chamber groups. He composed one work for the stage, a popular ballet called *The Incredible Flutist* (1938).

Piston was born in Rockland, Maine. He studied drawing and painting before choosing a career in music. From 1924 to 1926, he studied in Paris with composer Paul Dukas and the famous teacher Nadia Boulanger. Piston taught music at Harvard University from 1926 to 1960. Leonard W. Van Camp

Pit bull is a name commonly applied to any of several breeds or crossbreeds usually having some mixture of bulldog and terrier. Pit bulls were once used for attack-

ing bulls and bears and for dog-fighting matches. Pit bulls have occasionally attacked, and even killed, human beings. Breeds sometimes called pit bull include the *American pit bull terrier, American Staffordshire terrier, bull terrier, bulldog, bullmastiff,* and *Staffordshire bull terrier,* as well as various crossbreeds.

During the 1980's, the Humane Society of the United States reported that pit bulls were involved in about two-thirds of all deaths resulting from dog bites in the United States. Many people blamed pit bull attacks on the "natural aggressiveness" of the dogs. However, most experts faulted irresponsible owners, who may have abused the dogs or raised them to attack. Many experts also have stressed the difficulty of identifying a dog as a pit bull. According to the American Kennel Club and the United Kennel Club, no dog involved in a fatal attack had been registered by their clubs.

Largely as a result of pit bull attacks, some communities in the United States and Canada have passed laws to protect people from dangerous dogs. Some of these laws prohibit or restrict the ownership of certain breeds. Others require registration and liability insurance for owners of dogs that exhibit unprovoked, aggressive behavior. Michael W. Fox

Pitcairn Island is a small, isolated island in the South Pacific Ocean. It lies just south of the Tropic of Capricorn and about 5,000 miles (8,000 kilometers) east of Australia. For location, see **Pacific Islands** (map). Pitcairn is famous as the home of the mutineers of the British naval ship *Bounty.*

Pitcairn covers only about 2 square miles (5 square kilometers). The island rises sharply from the sea to an elevation of about 820 feet (250 meters). The interior is rugged, but it has fertile soil. The climate is mild. Average temperatures range from 75 °F (24 °C) in February to 66 °F (19 °C) in August. Rainfall averages 80 inches (200 centimeters) yearly.

Pitcairn is the main island of an overseas territory of the United Kingdom called the Pitcairn Islands Group. The other islands, all uninhabited, are Ducie, Henderson, and Oeno. The British high commissioner to New Zealand heads the territory's government. A council composed of Pitcairn residents directs local affairs.

About 60 people live on Pitcairn. Most of them are descendants of the *Bounty* mutineers and their Polynesian wives. Adamstown is the island's only settlement. Most of the people farm and fish for a living. The main crops are bananas, citrus fruits, coconuts, pumpkins, taro, watermelons, and yams. The people also sell hand-carved wooden figures to passengers of ships that stop at the island. The government gets much of its revenue by selling postage stamps that bear the words "Pitcairn Islands" to collectors.

Pitcairn was inhabited in prehistoric times, probably by Polynesians. However, no one was living there in 1767, when the English navigator Philip Carteret and his crew became the first Europeans to reach it. Carteret named the island after Robert Pitcairn, the crew member who first sighted the island.

In 1789, mutineers led by Fletcher Christian took control of the *Bounty* from Captain William Bligh in the South Pacific. Bligh and 18 nonmutineers were cast adrift in a small boat. In 1790, nine of the mutineers se tled on Pitcairn. These British sailors brought 19 Polyn sians with them—6 men, 12 women, and a young girl. Disputes over women eventually led to fighting amon the men. By 1808, when an American ship discovered the mutineers' hideout, all the men except the mutine John Adams were dead. But the mutineers had left 25 children. In 1856, many of Pitcairn's people moved to Norfolk Island. Robert Langdon

Pitch. See **Propeller** (Airplane propellers).

Pitch is a black, gluelike substance that is obtained b distilling coal tar. Pitch is highly adhesive and water re pellent. It is used for roofing materials, road pavings, and waterproofing applications. Pitch is also used in making the carbon *electrodes* (electrical poles) for the electrolytic cells that produce aluminum. Bob Willia

See also **Coal tar.**

Pitch is the characteristic of a sound determined by t *frequency of vibration* of the sound waves. High-pitch sounds have higher frequencies than low-pitched sounds. When violin players tune their instruments, th adjust each string so that it will vibrate at the desired f quency.

The pitch of most sounds we hear is actually due to blend of various frequencies. The sounds produced b musical instrument, a whistle, or a siren have several frequencies at the same time. The lowest frequency, called the *fundamental frequency,* is produced by an object vibrating as a whole. The higher frequencies, called *harmonics* or *overtones,* are produced by an ob ject vibrating in parts. For example, a violin string vibrates as a whole, and in halves, thirds, and so on at th same time. The overtones are whole number multiple of the fundamental frequency. A tuning fork produces sound wave of a single frequency. So do pitch pipes, which are used to get the correct number of vibration for certain notes. Physicists distinguish between pitch and frequency. They use the term *pitch* to refer to the psychological judgment of frequency, which depends on the loudness of the tone.

The notes we play and sing today did not always ha the same pitch. Composer George Frideric Handel tuned the A above middle C as low as 422.5 vibrations second. Today, the standard for pitch is the Stuttgart, c concert, pitch. It places A at 440 vibrations a second. Thomas A. Griffy

See also **Harmonics; Music** (Tone); **Sound** (Frequen and pitch).

Pitchblende is a variety of uraninite, a mineral that consists chiefly of uranium and oxygen. The ore is hig radioactive. In 1898, the French physicists Marie and Pierre Curie discovered radium, a rare element used i medicine and the physical sciences, in pitchblende. Pitchblende ranks as a major mineral source of uraniu which is used to produce nuclear energy.

The word *pitchblende* comes from *pitch,* a shiny su stance made from tar. Pitchblende has a tarlike luster and ranges in color from black to dark brown. Countri that have pitchblende deposits include Canada, the Czech Republic, France, Germany, South Africa, and th United States. Robert B. Cook

Pitcher, Molly (1754?-1832), was the fictitious name

ven to a woman who fought in the Battle of Mon-
outh in the Revolutionary War in America (1775-1783).
er real first name was Mary. Her last name, which may
ve been Ludwig, is in dispute. Mary was born near
iladelphia, and went to Carlisle, Pennsylvania, as a
rvant at an early age. She married William Hays, a
oung barber who lived in the village. Her husband en-
ted as a gunner in the First Pennsylvania Artillery in
75 and spent the winter of 1777 and 1778 at Valley
orge. Like many other poor women of the time, Mary
aveled with her husband. She received half-rations in
e Continental Army in return for cooking, washing,
wing, and doing other work.

The Battle of Monmouth was fought on June 28, 1778,
ne of the hottest days of a hot summer. The great heat
nd the fighting made the soldiers very thirsty. Accord-
g to legend, Mary carried water in a pitcher from a
earby spring to her husband's artillery station. The wa-
r was used to swab out the cannon after each shot,
nd to quench the soldiers' thirst. During the battle,
lary's husband fell from a heatstroke. She took his
ace and helped his crew fire the cannon. From these
ctions, she gained the nickname Molly Pitcher, repre-
entative of all women who fought valiantly in the war.

After the war, she and her husband returned to Car-
sle. Several years after Hays's death in 1787, she mar-
ed George McCauly (McCalla). He had been a soldier
the Revolutionary War and a friend of her first hus-
and. In 1822, the Pennsylvania state legislature awarded
lolly Pitcher a yearly pension of $40 in recognition of
er military service. James Kirby Martin

itcher plant is the name of a family of green plants
ith pitcher-shaped leaves that form traps for insects.
tcher plants are called *carnivorous plants* because they
ed on animal life (see **Carnivorous plant**). Like other
reen plants, pitcher plants make their own food by a
rocess called *photosynthesis* (see **Photosynthesis**).
owever, pitcher plants live in places where they get lit-
e nitrogen from the soil. The trapped insects provide
trogen for the plants. These unusual plants have many
cal names. Among these names are *sidesaddle flower, untsman's-cup,* and *Indian dipper.*

The common *northern* pitcher plant grows in
arshes and swamps east of the Rocky Mountains from
abrador south to Florida. The lower edges of its leaves
e folded together to form a tube, or pitcher. The top
dges are left open to form the lid, or spout. Rain water
ollects in these pitchers. Thick bristles grow at the
outh of each pitcher. These bristles all point down-
ard and inward. Tiny honey glands cover the inner sur-
ce of the lid. The smell of the sweet juice attracts in-
ects. Once the insect alights, the bristles prevent its
aving. It slides down to the base of the tube, where it
rowns. After a while, the plant digests the insect.

The globe-shaped flower of the pitcher plant grows
ngly on a long, slender stem. It is a deep reddish-
urple color. The people of the Canadian province of
ewfoundland and Labrador chose the pitcher plant as
eir provincial flower (see **Newfoundland and Labra-
or** [picture: Floral emblem]). A pitcher plant with yellow
owers grows in the Southern States. It has tall, erect,
umpet-shaped leaves. Another species of the pitcher
ant, the *cobra plant,* is native to California. Most in-
ects caught by this plant are killed. However, a certain
moth and a species of mosquito make their home in the
pitcher. Norman L. Christensen, Jr.

Scientific classification. Pitcher plants belong to the sarracenia family, Sarraceniaceae. The northern pitcher plant is *Sarracenia purpurea.* The southern pitcher plant is *S. flava.* The California pitcher plant is *Darlingtonia californica.*

See also **Plant** (picture: Plants that eat insects).

Pitohui, *PIHT oh HOO ee,* is the name of six species of songbirds found only in the forests of New Guinea. The pitohuis include the first known poisonous birds. Pitohuis have strong beaks and legs. Most of the species are sociable and live in small groups.

The feathers and skin of at least three species contain a strong poison. The poison probably keeps the pitohuis from being eaten by predators, such as snakes and hawks. Unlike some poisonous animals, pitohuis only use their poison to protect themselves. They are not known to use it to prey on or attack other animals.

The *hooded pitohui* is the most toxic of the three poisonous species. This bird is about 9 inches (23 centimeters) long. It has an orange-brown body with black wings, head, and tail. Curiously enough, its color pattern resembles that of the monarch butterfly, which is also poisonous and inedible to predators.

WORLD BOOK illustration by Colin Newman

The hooded pitohui is the most poisonous pitohui.

There are no known cases of a pitohui's poison causing serious harm to human beings. However, the village people of New Guinea, who hunt and eat native birds, call the pitohui a "rubbish bird" and rarely eat it.
Bruce M. Beehler

Scientific classification. Pitohuis belong to the tribe Pachycephalini in the subfamily Pachycephalinae, family Corvidae. The scientific name for the hooded pitohui is *Pitohui dichrous.*

Pitt, William (1708-1778), the first Earl of Chatham, was a British statesman. He is chiefly remembered as the "organizer of victory" and empire builder during the Seven Years' War (1756-1763) and for his powerful defense of the rights of the American colonists.

Pitt was born on Nov. 15, 1708, in Westminster. He was the son of a member of Parliament and attended Eton College and Oxford University. In 1735, he entered Parliament. From the first, he distinguished himself by his fiery attacks on Prime Minister Sir Robert Walpole and on the practice of subsidizing troops from the German *electorate* (territory) of Hanover with British money.

Pitt ended his attacks after he was appointed paymaster general of the British military forces in 1746. In this

office, he acquired a reputation for unusual honesty. Eventually, however, he bitterly denounced both the government's war policy and the weakness of its leader, the Duke of Newcastle. This action led directly to Pitt's dismissal in 1755. But he returned to office as secretary of state in 1756, when British military failures during the Seven Years' War led to Newcastle's fall from power. Pitt was again forced from office in 1757, but he returned the same year. "I know," he said, "that I can save this country, and that no one else can."

Pitt's task seemed insurmountable. On every side he found defeat and confusion. However, in five years, Britain gained great success, for which Pitt took the credit. He sent troops and money to Frederick the Great of Prussia and attacked France on all fronts. Great victories, especially in 1759, marked his policy everywhere. The French were defeated in India, America, Europe, and the West Indies, as well as on the sea. But other British ministers opposed Pitt when he demanded that war also be declared on Spain. He resigned as secretary of state in 1761.

During the next five years, Pitt resumed his opposition to the government. He denounced the Peace of Paris (1763) as far too lenient and aroused the British people to criticize the House of Commons. Pitt also denounced British policy toward the American colonists. As a result, he became an extremely popular figure in America.

Pitt was too powerful to remain out of office for long. In July 1766, he became prime minister and had his first opportunity at full control of the government. But his ministry lacked unity, and he lost political influence when he entered the House of Lords as the Earl of Chatham in August. He and his ministers proved incapable of solving troubles in America and India. Although Pitt had been an outstanding wartime leader, he had neither the patience nor the temperament for political cooperation and administration. He also failed to deal successfully with financial problems. Within a few months, Pitt was disabled by mental illness. He resigned his post as prime minister in October 1768.

Bettmann Archive

William Pitt

During the next 10 years, Pitt remained politically ineffective because of poor health. He supported parliamentary reform. He also protested against British policy in America and worked to satisfy grievances. Pitt's commitment to such causes limited his popularity in Britain, and he failed to gain much of a following. But he always remained capable of dominating his listeners, and his last speeches on the American war were among his best. Pitt's son William Pitt the Younger served as prime minister of Britain from 1783 to 1801 and from 1804 to 1806. J. C. D. Clark

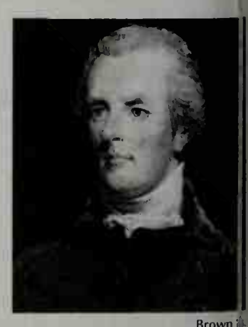
Ayling, Stanley E. *The Elder Pitt, Earl of Chatham.* McKay, 1976.
Black, Jeremy. *Pitt the Elder.* Cambridge, 1992.
Peters, Marie. *The Elder Pitt.* Addison Wesley Longman, 1998.

Pitt, William, the Younger (1759-1806), was a Briti statesman. He became Britain's chancellor of the exchequer at the age of 23 and prime minister at 24. He was the youngest person ever to hold either post. Pitt serve as the prime minister of Britain from 1783 to 1801 and from 1804 to 1806. He also dominated British politics b tween those two terms. He was the son of William Pitt, Earl of Chatham, who was also a leading British statesman.



William Pitt the Younger was born in Kent and entered Cambridge University at the age of 14. After grac uation in 1776, he studied law. He was admitted to the bar in 1780, but his main interest lay in politics. In January 1781, Pitt entered Parliament. His amazing abilities quickly made him outstanding. His first speech, always one of the most difficult tests in politics, was remarkable. In committee work, he was informed, penetratin and self-possessed.

Almost immediately, Pitt began to press for parliamentary reform and the reduction of the influence of t king. He quickly gained favor with the older politicians He served as chancellor of the exchequer in 1782 and 1783.

In December 1783, Pitt became prime minister. He held this office for the next 17 years. During the first three months, he experienced great difficulty in the House of Commons because he single-handedly had t meet the attacks of the opposition, led by Charles Jam Fox, Edmund Burke, Richard Brinsley Sheridan, and Lord North. In March 1784, however, Pitt called for a new election and scored a great triumph. This provide him with a majority in the House of Commons.

Pitt then turned his attention to improving the Britis economy. He increased government revenue, funded the national debt, improved the government's credit, and negotiated a free-trade treaty with France. He extended the authority of the British government over India. But Pitt also had troubles. King George III suffere from a disease—probably porphyria—that, beginning i 1788, made him appear to be mentally ill. Pitt had to struggle against a Whig party campaign to name the Prince of Wales as regent. Pitt feared that if the Whigs succeeded, they would take over the government. George's recovery in 1789 relieved the situation.

A more important problem—the French Revolution soon challenged Pitt. At first, he failed to sense its sign icance. But his attitude changed when France declarec war on Britain in 1793. Pitt organized a vast coalition o European countries to fight France. After some succes es, the alliance suffered military defeats. Several nations left the alliance. After the rise of Napoleon Bonaparte in France, the situation grew steadily worse. Pitt entered into peace negotiations with the French government, but was unsuccessful. The dismal end came when Napoleon's triumphs over Austria brought about Austria's withdrawal from the coalition.

Brown

William Pitt the Younge

Britain remained at war with France, and Napoleon in-
ded Egypt in 1798 to destroy British trade with the
iddle East. But after Napoleon had arrived in Egypt, a
itish fleet destroyed his fleet in the Battle of the Nile.
t then helped form a second coalition of nations
ainst France, and the coalition defeated the French
ny in Italy. But Napoleon returned to France and, in
00, scored a decisive victory against the coalition.

Pitt resigned from office in March 1801 after his fail-
e to persuade George III to allow Roman Catholics to
ter Parliament at the time of the Act of Union. The Act
Union had formed the United Kingdom of Great Brit-
n and Ireland earlier in 1801. Pitt returned to office in
04 to organize a third coalition of nations against Na-
leon.

This coalition also fell before the French, and its fail-
e proved disastrous to Pitt. He was sadly troubled al-
ady because of the king's worsening health problems
d his own poor health and disorganized finances. He
uld not survive the military defeats of the United King-
m's allies. Even Admiral Horatio Nelson's astounding
val victory at Trafalgar in 1805 could not make up for
e losses. Though Pitt could say "England has saved
rself by her exertions, and will, I trust, save Europe by
r example," he also recognized the significance of
poleon's victory at Austerlitz. "Roll up the map," he
id of a map of Europe, "it will not be wanted these ten
ars." James J. Sack

ttsburg Landing, Battle of. See Civil War (Battle Shiloh).

ttsburgh is the second largest city in Pennsylvania.
nly Philadelphia has more people. Pittsburgh lies in the
lling hills of southwestern Pennsylvania, where the Al-
gheny and Monongahela rivers meet and form the
nio River.

During the late 1800's, Pittsburgh became the world's
ading producer of steel. Massive mills turned out steel
r automobiles, ships, trains, and numerous other
oducts. Pittsburgh earned the nickname the *Steel City.*

Steel production gave Pittsburgh a booming econo-
y. It also caused severe pollution, however. Some-
nes, the air became so polluted that during the 1940's,
wntown streetlights had to be turned on during day-
ne. Some people mocked Pittsburgh as the "Smoky
ty." In the early 1950's, Pittsburgh began a major urban
newal program. The program included strict controls
industry and coal-burning furnaces. These steps
eatly reduced pollution in the city.

Most of Pittsburgh's big steel mills are gone. The city
still an important steel producer, but it has a much
ore varied economy than it had in the past. Service in-
istries, especially health and medical, now contribute
eatly to the economy.

Settlers first came to the area that is now Pittsburgh in
e 1750's. The British and the French both claimed the
ea. The area was a scene of fighting between the
itish and French during the 1750's. The British military
ilt a fort there in 1758. They named it Fort Pitt in honor
of William Pitt, who later became Britain's prime minis-
ter. British settlers established a community around the
fort and named it Pittsburgh.

The city

Layout of Pittsburgh. Pittsburgh covers 56 square
miles (145 square kilometers) in the center of Allegheny
County. Much of downtown Pittsburgh lies in a wedge-
shaped area between the fork of the Allegheny and
Monongahela rivers. This area, called the Golden Trian-
gle, features skyscrapers that house offices and shops.
Most of Pittsburgh's major corporations have their
headquarters in or near there. They include Alcoa Inc.,
Mellon Bank, PPG Industries, and United States Steel
Corporation. The 64-story U.S. Steel Tower ranks as one
of the tallest buildings in Pennsylvania.

The western tip of the Golden Triangle—where the
Ohio River begins—is called the Point. Old factories and
warehouses formerly crowded the Point. But those
buildings were torn down at the start of Pittsburgh's ur-
ban renewal program in the 1950's. In their place, devel-
opers established scenic Point State Park and a new of-
fice complex called Gateway Center. Large numbers of
workers commute to and from downtown Pittsburgh,

Facts in brief

Population: *City*—334,563. *Metropolitan area*—2,358,695.
Area: *City*—56 mi² (145 km²). *Metropolitan area*—4,624 mi² (11,976 km²).
Climate: *Average temperature*—January, 29 °F (−2 °C); July, 72 °F (22 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—40 in (100 cm). For the monthly weather in Pittsburgh, see **Pennsylvania** (Climate).
Government: Mayor-council. *Terms*— 4 years for the mayor and 9 council members.
Founded: 1758. Incorporated as a city in 1816.

© Jim Sch

Downtown Pittsburgh lies in a triangle-shaped area bordered by two rivers, the Allegheny, spanned by the bridge at the left; and the Monongahela, at the right. Its skyscrapers house most of the city's major corporations. The area at the tip of the triangle is Point State Park.

mostly by automobile. Bridges over the rivers serve the cars. Pittsburgh has more than 450 bridges, more than any other United States city.

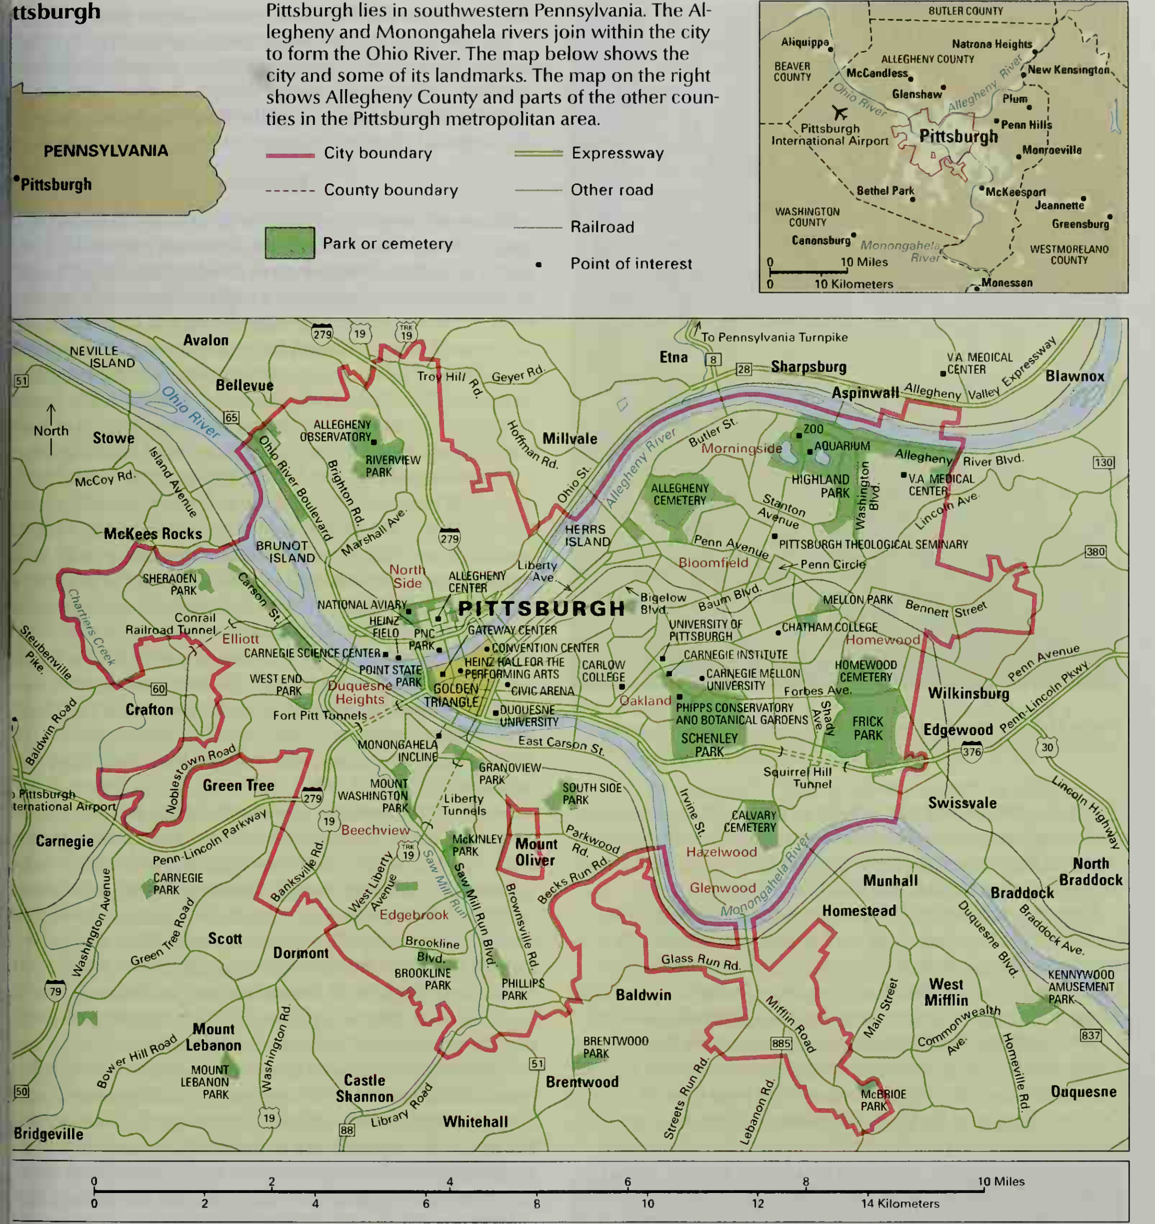
A hill called Mount Washington overlooks downtown Pittsburgh. It rises 450 feet (137 meters) and stretches for several miles along the Monongahela River. It features observation decks and restaurants that offer spectacular views of Pittsburgh and its three famous rivers. Two small cable car lines, called "inclines" by Pittsburghers, carry visitors up and down Mount Washington.

The Civic Arena stands just east of Pittsburgh's business area. Its domed roof can be opened so that musical and stage events can be held in the open air when weather permits.

Residential areas spread out beyond downtown. Industrial activity is scattered throughout the region.

The metropolitan area. Pittsburgh's metropolitan area covers Allegheny, Beaver, Butler, Fayette, Washington, and Westmoreland counties. It includes about 200 communities. Penn Hills is Pittsburgh's largest suburb. Other big suburbs include Bethel Park, McCandless, Monroeville, and Mount Lebanon.

The Pittsburgh metropolitan area includes a number of communities which, like Pittsburgh itself, formerly depended on the production of steel. These communities include Duquesne, Homestead, and McKeesport. When their mills closed, the towns suffered economically. Like Pittsburgh, they are working to build a varied economy.



People

Ethnic groups. Early in its history, Pittsburgh attracted people from many parts of Europe. The first settlers came from England. Large numbers of German, Irish, Italian, and Polish people settled in the city during the 1800's. Pittsburgh still has an old neighborhood called Polish Hill, where Polish is spoken as often as English. Many Croats, Hungarians, and Serbs came to work in the steel mills and settled in Pittsburgh about 1900.

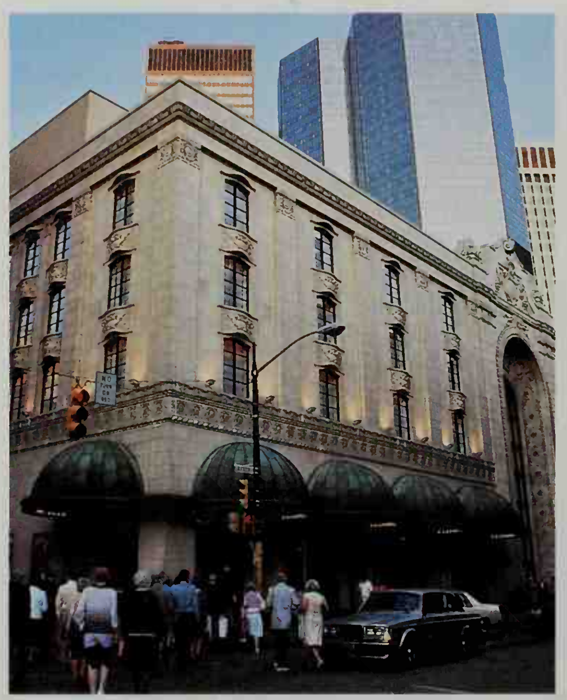
African Americans account for approximately a four of Pittsburgh's population. Large numbers of African Americans began moving there in the early 1900's. Fro the 1930's through the 1950's, Pittsburgh's Hill District was one of the most prosperous African American co munities in the United States. Today, many African Americans live near the center of the city. Some black live in the suburbs, including Penn Hills and Wilkinsburg.

Housing. Pittsburgh's East End includes well-kept neighborhoods with housing ranging from relatively i expensive duplexes to lavish mansions. Part of the Nor Side includes houses that are more than 100 years old They have been restored to reflect their original condi tion and beauty. Crawford Square is a development of single-family homes, town houses, and apartments ne the Civic Arena, close to downtown. The city government and private developers worked together to buil it. Some of the older homes near downtown stand on the steep hillsides. The hills are so steep that many buildings are two stories high in front and four or mo stories in back.

Education. The public schools of Pittsburgh serve about 40,000 students. Pittsburgh's Roman Catholic di cese, which covers six counties, has about 35,000 students in its elementary and high schools. The Pittsbur area is also a center of higher education. It includes about 30 colleges and universities. The University of Pittsburgh ranks as the area's largest school of higher

Pittsburgh lies in southwestern Pennsylvania. The Allegheny and Monongahela rivers join within the city to form the Ohio River. The map below shows the city and some of its landmarks. The map on the right shows Allegheny County and parts of the other counties in the Pittsburgh metropolitan area.

WORLD BOOK maps



ducation. Other area schools include Carnegie Mellon niversity; Duquesne University; Pittsburgh Theological eminary; and Carlow, Chatham, La Roche, Point Park, nd Robert Morris colleges.

Social problems. Pittsburgh, like other large urban eas, has a number of social problems. They include reet crime and illegal drug sales and use. Pittsburgh rmerly experienced severe air and water pollution. But ontrols and cooperation have led to a major reduction the pollution problem.

Cultural life

The arts. The Pittsburgh Symphony Orchestra presents concerts downtown at Heinz Hall for the Performing Arts. The Benedum Center for the Performing Arts is the home of several groups. They are the Pittsburgh Ballet Theatre, Pittsburgh Opera, Pittsburgh Dance Council, and Civic Light Opera. The Pittsburgh Public Theater offers professional regional theater. The annual Three Rivers Arts Festival, held each June in Point State Park and the Golden Triangle, features works by painters, sculptors, and musicians. The Star Lake Amphitheatre in Washington County presents outdoor concerts.

Museums and libraries. Pittsburgh's Carnegie Institute includes the Museum of Natural History and the Museum of Art. The natural history museum features a collection of dinosaur fossils. The art museum includes the Heinz Architectural Center and Hall of Architecture.

© Jack A. Wolf

Heinz Hall for the Performing Arts, in the downtown area, is the home of the world-famous Pittsburgh Symphony Orchestra.

The Carnegie Science Center presents science shows and other programs. The Andy Warhol Museum houses many of the most famous works by Warhol, a major Pop artist who was born in Pittsburgh.

Carnegie Library of Pittsburgh is the city's public library. It is named for Andrew Carnegie, a Pittsburgh steel manufacturer, who founded it in 1895. The Carnegie Library of Pittsburgh system includes a main library at the Carnegie Institute and several branches.

Recreation. The Pittsburgh area has more than 150 parks, fields, playgrounds, and playlots. Schenley Park is one of Pittsburgh's largest parks. It includes the Phipps Conservatory and Botanical Gardens, which houses a rich collection of plants and flowers in one of the few remaining Victorian greenhouses in the United States. Highland Park is home of the Pittsburgh Zoo and the Aquarium. The National Aviary in Pittsburgh houses about 200 species of birds in a natural setting with plants, pools, and waterfalls. Exhibits at the Pittsburgh Children's Museum encourage personal participation. Suburban areas include several large county parks that offer biking, hiking, horse riding, swimming, and ice skating. Suburban Raccoon Creek State Park, in Hookstown, includes a large lake and a wildflower reserve. Kennywood Amusement Park, in West Mifflin, is famous for its fast roller coasters.

Each August, the Three Rivers Regatta brings spectators downtown to see speedboat races and fireworks. The riverboats of the Gateway Clipper Fleet offer dining, dancing, and sightseeing tours of downtown the year around. Fort Necessity National Battlefield, in Farmington south of Pittsburgh, marks the site of the Battle of Fort Necessity of 1754. The battle was one of the first of the French and Indian War, which began that year.

Pittsburgh is the home of three professional sports teams. They are the Pittsburgh Pirates baseball team of the National League, the Pittsburgh Steelers of the National Football League, and the Pittsburgh Penguins of the National Hockey League.

Economy

The economy of the Pittsburgh area went through a major change in the 1980's. It had been dependent on heavy industry—notably steel production—but it began to develop more variety and balance. Unemployment rose as heavy industry declined, but the development o other economic activities helped improve economic conditions. Today, service industries contribute heavily to the area's economy, employing about 370,000 peopl Health care and retail trade are the largest service indu tries. Manufacturing employs more than 130,000 peopl

Manufacturing. Pittsburgh's steel mills formerly pro duced all kinds of steel. Today's remaining mills chiefly turn out specialty steel, which is used to make tools an automobiles. This type of steel is of higher quality and more profitable than types made in earlier years. Pittsburgh factories also produce glass products, fabricate metals, chemicals, and machinery.

Pittsburgh's largest private employers include Alcoa, the world's biggest aluminum producer; United States Steel Corporation, a leading steelmaker; and PPG Indus tries, a glass, paint, and chemical manufacturer. The H. Heinz Company makes ketchup, pickles, and other foo products.

Service industries. The Pittsburgh area ranks as a major center of health care. About 90 hospitals serve th area. The University of Pittsburgh runs a medical cente specializing in liver, kidney, heart, and lung transplants

Research and development is also a major service in dustry. More than 170 academic, industrial, and govern mental research laboratories operate in the Pittsburgh area. Their engineers, scientists, and technicians work i such fields as medical technology, computer software programming, and industrial automation.

Transportation and communication. Pittsburgh In ternational Airport is in southwestern Allegheny Count Two major railroads and four interstate highways serv the city. A trolley-subway connects downtown with southern suburbs. Pittsburgh's rivers are used to ship raw materials to, and finished products from, the city.

Pittsburgh has one daily newspaper, the morning *Pittsburgh Post-Gazette*. The *Tribune-Review* in nearby Greensburg also publishes a Pittsburgh edition. Severa smaller daily newspapers published in towns surround ing Pittsburgh serve the area's suburban population. KDKA became one of the first commercial radio station in the United States when it began broadcasting in 192 For more details, see **Radio** (The start of broadcasting).

Government

The city of Pittsburgh has a mayor-council form of government. Voters elect the mayor and the nine coun cil members to four-year terms. Most of the city's revenues come from a wage tax and property taxes. In the 1990's, to reduce its spending, the city turned over thre city institutions to private groups to own and manage. The three were the Pittsburgh Zoo, the Phipps Conser

ory and Botanical Gardens, and the National Aviary in ttsburgh. Pittsburgh is the seat of Allegheny County.

In addition to the city government, the Pittsburgh area is dozens of other government bodies. They include iburban municipal governments, local boards of edu- tion, and county government.

History

Early days. In the 1740's, French soldiers claimed the ea that is now Pittsburgh for the king of France. Many dians traded goods with French and Canadian traders. ie Iroquois of western New York had chased the origi- il tribes out of the area in the 1600's.

Both Britain (now the United Kingdom) and France ought to gain control of the region, and this competi- on led to the French and Indian War (1754-1763). In '54, French troops built Fort Duquesne at the fork of e Allegheny and Monongahela rivers. George Wash- gton built Fort Necessity south of Fort Duquesne. 'ashington, later the first United States president, was en a 22-year-old lieutenant colonel in Britain's Virginia ilitia. The French defeated Washington's troops in the ittle of Fort Necessity and forced Washington to sur- nder the fort. The battle marked one of the first mili- ry actions of the French and Indian War.

In spite of their early defeat, the British won control of e Pittsburgh area in 1758. They built Fort Pitt near the rk of the Allegheny and Monongahela rivers. A settle- ent grew up around the fort and became Pittsburgh. ie American colonists won independence from Britain the Revolutionary War (1775-1783). After the war, Pitts- irgh became a starting point for pioneers traveling est. Pittsburgh became the Allegheny County seat in '88 and was incorporated as a borough in 1794.

Industrial development. Demands from Western ttlements for manufactured goods caused industry to ow rapidly in Pittsburgh. The city was incorporated in 16. It then had a population of about 5,000. Nearby de- osits of coal and oil helped make Pittsburgh an iron- aking and glassmaking center by the mid-1800's.

Transportation developments also helped industry ow in Pittsburgh. In 1811, the first steamboat to travel i the Ohio and Mississippi rivers was launched from tsburgh. The Pennsylvania Canal System, which con- cted Pittsburgh and Philadelphia, opened its main line 1834. A railroad entered Pittsburgh in 1851. By then, ore than 46,000 people lived in the city.

The American Civil War (1861-1865) created a great mand for arms and ammunition. Pittsburgh became a ief supplier for the Union Army. During the late 00's, steel manufacturers Andrew Carnegie and Henry ay Frick built industrial empires in the city. Pittsburgh el mills played an important role in America's growth. ey supplied great amounts of steel to build bridges, tories, and railroads. Steady industrial growth attract- thousands of workers to Pittsburgh during the late 00's. Many came from southern and central Europe. om 1870 to 1900, the city's population more than pled, jumping from 86,076 to 321,616. By 1900, half of world's glass and iron came from Pittsburgh's facto- s. The city's steel mills made two-thirds of the steel oduced in the United States by 1900.

The early 1900's. The arrival of more immigrants m Europe and of many blacks from the southern United States helped boost the population of Pittsburgh to 669,817 by 1930. In 1936, the Allegheny and Monongahela rivers flooded the Golden Triangle, causing 74 deaths and damaging thousands of homes.

World War II. In December 1941, the United States joined the side of the Allies in their World War II fight against the Axis nations. From then until the Allied victory in September 1945, the Pittsburgh area's mills and factories operated at full capacity to provide steel, glass, and other products for the war effort. During the war, mills of the Pittsburgh area turned out more steel than did the Axis countries of Germany and Japan combined.

Also during World War II, Pittsburgh became one of the first cities in the United States to construct large amounts of public housing. Thousands of people moved to the city to take jobs in its booming war-related industries. The inflow of people caused a housing shortage and led the city and federal governments to construct low-rent public housing for workers.

Urban renewal. In 1946, Mayor David L. Lawrence, financier Richard K. Mellon, and many other civic and corporate leaders began an urban renewal program in Pittsburgh that would become the first such program in the United States. The city started strict smoke-control and water pollution-control programs to clean up Pittsburgh's polluted air and water. By the 1960's, most of the clean-up efforts had been completed. Pittsburgh's population reached its highest point of 676,806 in 1950. In the 1950's and 1960's, many white residents moved out of the city to surrounding suburbs.

The first stage of urban renewal, known as Pittsburgh's Renaissance I, ended in the early 1970's. The factories and warehouses in the Golden Triangle had been torn down and replaced with Point State Park and Gateway Center in the 1950's. The Civic Arena and the U.S. Steel Tower had been completed in the 1960's. A second project, Renaissance II, began during the 1980's. It produced a convention center, a trolley-subway system, and several new skyscrapers, including PPG Place.

Recent developments. Between 1980 and 1990, the population of Pittsburgh dropped from 423,959 to 369,879, largely because of economic problems. Many young people moved to other cities to find work. During the 1990's, unemployment declined as new jobs in

Smoke from Pittsburgh's steel mills darkened the skies in this picture from the 1940's, before industry controls reduced air pollution. But steel production also benefited Pittsburgh's economy.

health care and other occupations became available. Pittsburgh International Airport opened in 1992, adding to the area's role as a transportation center. Despite these developments, Pittsburgh's population fell again between 1990 and 2000, to 334,563. Bill Steigerwald

Pittsburgh, University of, is a privately controlled, state-supported school in Pittsburgh. The university offers programs in liberal arts and sciences and in numerous professions, including medicine, law, library and information science, engineering, and social work. It has 14 graduate and professional schools and over 25 specialized research centers. It is an important health center and is known worldwide for its organ transplant program. Courses lead to bachelor's, master's, and doctor's degrees. The university also has campuses in Bradford, Greensburg, Johnstown, and Titusville. It was founded in 1787. Critically reviewed by the University of Pittsburgh

Pituitary gland, *pih TOO uh TEHR ee,* is one of the body's most important glands. It secretes a number of hormones, which control a wide range of body functions. The pituitary gland, also called the *hypophysis,* is about the size of a pea and lies under the brain near the center of the skull. A short stalk connects the pituitary to the *hypothalamus,* a part of the brain.

The pituitary has two main sections—the *anterior lobe* (front part) and the *posterior lobe* (rear part). The anterior lobe secretes several hormones. Four of these hormones control the secretions of other hormone-producing glands. The four hormones and the glands they control are *adrenocorticotropic hormone* (ACTH), the adrenal glands; *follicle-stimulating hormone* (FSH) and *luteinizing hormone* (LH), the sex glands; and *thyroid-stimulating hormone* (TSH), the thyroid gland. Secretions from these glands, in turn, signal the pituitary to decrease secretion of the hormones controlling them.

The anterior lobe of the pituitary also produces *growth hormone* (GH), which regulates the growth of children and adolescents. Growth hormone also helps

WORLD BOOK illustration by Leonard Morgan

The pituitary gland is one of the body's chief hormone-producing organs. It consists of two main parts—the anterior and posterior lobes—and it rests in a bony depression at the base of the brain. A short stalk connects the pituitary to the brain.

control the way food is utilized in people of all ages. *Pr lactin,* another hormone of the anterior lobe, stimulates milk production in nursing mothers. The hypothalamus plays an important role in regulating the anterior lobe of the pituitary. It produces *releasing hormones* that govern the release of secretions from the anterior lobe.

The posterior lobe of the pituitary gland stores two hormones, *antidiuretic hormone* (ADH, also called *vaso pressin)* and *oxytocin.* The hypothalamus manufactures and triggers the release of both these hormones. Antidiuretic hormone causes the kidneys to retain sufficient water for the body. Oxytocin causes the uterus to contract during childbirth and stimulates the release of mil during nursing. Charlotte H. Greene

Pius IV (1499-1565) was elected pope in 1559. He successfully put into effect many key reform measures of the church renewal movement called the Counter Refo mation. His major achievement was reconvening the Council of Trent. The council had been suspended in 1552, and Pius reopened it in 1562. Pius was a shrewd and diplomatic man, and he used these qualities to help the council complete its business in 1563. The council established the basic framework of Roman Catholic reform (see **Trent, Council of**). Pius also reformed the Roman Curia, the pope's administrative arm.

Pius helped revive the cultural and intellectual life of Rome and had several notable structures built, including the Porta Pia arch and the Villa Pia in the Vatican ga dens. In his endeavors, Pius relied on the aid of his nephew, Saint Charles Borromeo.

Pius was born March 31, 1499, in Milan, Italy. His given and family name was Giovanni Angelo de' Medici. H died on Dec. 9, 1565. Charles L. Stinger

Pius V, Saint (1504-1572), was elected pope in 1566. H typified the intense religious feeling of Roman Catholicism during the church renewal movement called the Counter Reformation. Pius was solemn, devout, and ascetic. As pope, he tried to impose rigid standards of piety and morality on clergy and lay people. He worked to put into effect the reforms established by the Counc of Trent by publishing the Roman Catechism and other important devotional documents (see **Trent, Council o**

Pius was an uncompromising enemy of Protestantism He was equally determined to stop the advance of Isla He formed the Holy League with Venice and Spain that won a dramatic victory over the Muslim Ottoman Empire at the Battle of Lepanto in 1571.

Pius was born on Jan. 17, 1504, in Bosco, Italy, near Alessandria. His given and family name was Michele Ghislieri. He died on May 1, 1572, and was *canonized* (declared a saint) in 1712. His feast day is April 30.

Charles L. Stinger

Pius VII (1742-1823) was elected pope of the Roman Catholic Church in 1800. He was pope during the difficult years that Napoleon I of France controlled much o central and western Europe, and during the European settlement that followed Napoleon's defeat in 1815. At first, Pius followed a conciliatory policy with Napoleon He made an agreement with Napoleon that settled the confused French religious problem. The agreement

ıided church-state relations in France for over 100 ıars. In 1804, Pius crowned Napoleon emperor in Paris. However, as Napoleon increased his demands, Pius ffened his resistance. He refused to join the continen- blockade against England, and he refused to grant ıpoleon a divorce from Josephine. In 1809, Napoleon nexed the Papal States. Pius excommunicated all who ok part in this action. He was arrested and held in Fon- nebleau until 1814. Pius's strong stand against Napole- ı won him the admiration of the European powers. ıey supported his bid to reclaim the Papal States after ıpoleon's defeat.

Pius was born on Aug. 14, 1742, in Cesena, Italy. His ven and family name was Gregorio Luigi Barnaba ıiaramonti. He became a Benedictine monk at the age 14. Pope Pius VI named him a cardinal in 1785. Pius VII ed on Aug. 20, 1823. Gerald P. Fogarty

us IX (1792-1878) was elected pope of the Roman ıtholic Church in 1846. He enjoyed the longest reign in pal history. His early acts as pope promised a liberal d popular government for the Papal States. He par- ıned political prisoners, admitted lay people to the ıvernment, and promised a constitution. He fled Rome 1848 when revolutionists made the city a republic. ter his restoration in 1850, Pius followed a highly con- rvative policy in government matters.

In 1854, Pius defined the doctrine of the Immaculate ınception of the Virgin Mary as an article of Roman tholic dogma (see **Immaculate Conception**). Ten ars later, he issued the *Syllabus of Errors,* a collection propositions that gave the impression that Pius was ıposed to all progress and to modern civilization.

The outstanding event of Pius IX's reign was the as- mbling of Vatican Council I in 1869, the first general uncil since the 1500's. The council declared that the pe had *primacy of jurisdiction*—that is, he was first in portance—over the whole church. The council also proved the doctrine of *papal infallibility.* For a descrip- n of this doctrine, see **Vatican Council I.**

Italy took the Papal States and Rome by force during ı unification in the 1860's and 1870's. Pius became a luntary prisoner in the Vatican. He refused any accord ıt did not recognize him as a sovereign ruler. He be- ved that he would be looked on as "the Italian king's aplain" if he settled for less. See **Italy** (Italy united).

Pius was born on May 13, 1792, in Senigallia, Italy. His ven and family name was Giovanni Maria Mastai- rretti. He was ordained a priest in 1819, created an chbishop in 1827, and made a cardinal in 1840. As chbishop of Imola, he was noted for his liberal sympa- es and his criticism of the conservative Pope Gregory I. Pius died on Feb. 7, 1878. Gerald P. Fogarty

us X, Saint (1835-1914), was elected pope of the Ro- ın Catholic Church in 1903. Pius was theologically nservative. In 1907, he issued an *encyclical* (letter to ı entire church) and other statements condemning *odernism.* Modernism was a general trend to adopt w theological methods and to apply historical criti- m to the Scriptures. Pius had an important impact on tholic spiritual life. He encouraged frequent reception the Eucharist, admitted children of the age of reason Communion, and encouraged the use of the Gregori- chant in the liturgy.

Pius was born on June 2, 1835, in Riese, Italy, near Tre- viso. His given and family name was Giuseppe Melchi- orre Sarto. He was ordained a priest in 1858. In 1893, Pope Leo XIII named him patriarch of Venice and a car- dinal. Pius was widely regarded as a saint during his life- time. He died on Aug. 20, 1914, and was *canonized* (de- clared a saint) in 1954. Gerald P. Fogarty

See also **Roman Catholic Church** (Pius X).

Pius XI (1857-1939) was elected pope of the Roman Catholic Church in 1922. In 1929, he negotiated the Lat- eran Treaty that ended a long conflict between the papa- cy and the Kingdom of Italy called the "Roman question." The treaty gave the pope sovereignty over Vatican City (see **Papal States**). Pius was increasingly confronted by the rise of totalitarian governments in Europe. In 1931, he issued an *encyclical* (letter to the entire church) con- demning Italian Fascism. He negotiated a *concordat* (agreement) with Nazi Germany in 1933 but condemned Nazism and Communism in separate encyclicals in 1937. However, in 1936, he supported dictator Francisco Fran- co in the Spanish Civil War against the republican gov- ernment's increased persecution of the Catholic Church.

Pius was born on May 31, 1857, in Desio, Italy, near Milan. His given and family name was Ambrogio Dami- ano Achille Ratti. He was ordained a priest in 1879, and Pope Benedict XV named him a cardinal in 1921. Pius died on Feb. 10, 1939. Gerald P. Fogarty

Pius XII (1876-1958) was elected pope of the Roman Catholic Church in 1939. He was one of the most active popes in church history. Pius used his authority to such an extent that he was sometimes criticized within his church for determining too many issues. But he also was widely praised for the broad range of his interests and his brilliance in attacking basic problems of the church.

Pius negotiated with the heads of several European nations to try to prevent World War II, and to end the war as soon as possible after it began in 1939. He is credited with secret arrangements that saved tens of thousands of Jews from death by the Nazis. After his death, some people blamed Pius for not speaking out more forcefully against Nazi persecution of Jews. Other people believe Pius felt further appeals to Adolf Hitler were useless and that such appeals might have in- creased Nazi persecution of Jews in Italy and elsewhere.

In the area of church teaching, Pius in 1950 pro- claimed the Assumption of the Blessed Virgin into heav- en. His *encyclicals* (letters to the entire church) covered a wide range of topics. *Divino Afflante Spiritu* (1943) opened the way for Catholic Biblical scholarship. *Media- tor Dei* (1947) prepared for the updating of the Catholic Mass in the 1960's. Pius altered some customs, such as shortening Holy Week ceremonies and relaxing the law of fasting before Holy Communion.

Pius was born on March 2, 1876, in Rome. His given and family name was Eugenio Pacelli. He was ordained a priest in 1899 and was named a cardinal in 1929. He served as papal secretary of state from 1930 until his election as pope. Pius died on Oct. 9, 1958.

Pizarro, *pee THAHR roh* or *pih ZAHR oh,* **Francisco,** *frahn THEES koh* or *frahn SIHS koh* (1478?-1541), was a Spanish conqueror. His conquest of the Inca empire in Peru opened the way for Spain's colonization of most of South America.

Early life. Pizarro was born in Trujillo, Spain. His father was a royal captain of infantry. Francisco's parents never married each other. Poor relatives of his mother raised the boy, who never learned to read. In 1502, Pizarro left for the West Indies. He lived for a while in Hispaniola, the main Spanish base in the New World.

First expeditions. In 1509, Pizarro left Hispaniola to take part in exploration of the Caribbean coast of northern South America and southern Central America. He served as Vasco Nunez de Balboa's chief lieutenant when Balboa marched across the Isthmus of Panama to the Pacific Ocean in 1513 (see **Balboa, Vasco Nunez de**). Six years later, the Spaniards founded Panama City on the Pacific coast. Pizarro was one of its wealthiest and most powerful citizens.

The Spaniards in Panama City became interested in reports of a rich Indian empire somewhere to the south. In 1524, Pizarro began the first of several expeditions to search for this empire. He was helped by another Spaniard, Diego de Almagro, who served chiefly as business manager of the expeditions. Pizarro led the explorations down the Pacific coast. At first, bad weather and Indian attacks prevented the voyagers from finding the empire, which was centered in what is now Peru. Pizarro finally reached his goal in late 1527 or early 1528.

Conquest of Peru. Pizarro saw much evidence of gold and other riches in Peru. He soon returned to Spain, and King Charles I appointed him governor of Peru. In 1531, Pizarro sailed from Panama City with about 180 men. They landed in what is now Ecuador. In 1532, they founded San Miguel (now Piura) in northern Peru.

Detail of *Pizarro Seizing the Inca of Peru* (1846), an oil painting by Sir John Everett Millais (Bridgeman Art Library)

Francisco Pizarro conquered the Inca empire in western South America for Spain. This picture shows him capturing the Inca ruler Atahualpa in a famous battle at Cajamarca in 1532.

WORLD BOOK m

Pizarro's expeditions led to the Spanish conquest of the Inca empire in 1533. Pizarro began to look for the empire in 1524 an finally found it in Peru about four years later.

Pizarro next advanced to Cajamarca, where the Inca ruler Atahualpa had gathered his forces. In a surprise a tack with swords, horses, and a few guns, Pizarro's me captured Atahualpa and killed thousands of Inca. The Spaniards promised to spare Atahualpa's life in return for vast riches. The Inca were able to agree to the ransom because Peru had more silver and gold than any other part of the Americas. But in 1533, after receiving large treasure, the Spaniards executed Atahualpa (see **Atahualpa**). Pizarro then advanced southward to Cusco the Inca mountain capital. The conquerors took contro of the city later in 1533.

Later life. In 1535, Pizarro founded the city of Lima and made it Peru's capital. While he was governor of Peru, many Spaniards settled there. The settlers starte mining great amounts of silver and gold and began to build many cities. Using Peru as its base, Spain conquered most of the rest of South America.

In the late 1530's, a dispute between Pizarro and Almagro over who was to rule the area around Cusco le to war. Pizarro's forces won the conflict in 1538 and ex cuted Almagro. On June 26, 1541, followers of Almagr son killed Pizarro. James Lockhart

Pizza is a popular food made by baking a flat bread dough topped with cheese, tomato sauce, and herbs. Most pizzas are topped with other ingredients as well. Popular toppings include Italian sausage, mushrooms, onions, pepperoni, and peppers.

Pizza is made in many different forms. *Neapolitan pi za* is thin and round. *Sicilian pizza* is rectangular and thick. In a *Chicago style pizza,* layers of toppings fill a high-edged crust in a deep pan. A *New York style pizz* has a thin crust with a thick, puffy outer edge. A *calzo* is folded pizza dough baked with the toppings inside.

People of ancient Middle Eastern and Mediterrane cultures made an early form of pizza by baking bread with simple toppings on stones in a wood-fired oven.

t pizza as we know it today originated in Naples, Italy. 1889, Raffaele Esposito, a baker, created a special dish honor the visiting king and queen of Italy, Umberto d Margherita. Esposito topped Neapolitan flat bread th green basil, white mozzarella cheese, and red nato sauce to reflect the colors of the Italian flag. any bakers soon copied the dish. John G. Reilly

(U. See **Phenylketonuria**.

ace value. See **Numeration systems**.

acebo, *pluh SEE boh,* is a substance that doctors metimes use as a medicine, even though it contains active ingredient. A placebo brings about an im- ovement or even a cure in some patients. Placebos ok like real drugs but contain only inactive substances, ch as sugar. Doctors also may administer placebo in- ctions, which usually contain salt water or sterile wa- , and may even perform placebo surgery.

Doctors believe the effectiveness of placebos de- nds on the patient's belief that the substance is really edicine. In many cases, this belief provides a psycho- gical boost that can improve the patient's symptoms. A isting relationship between the patient and doctor can crease the placebo's effectiveness. There is also some idence that *endorphins* and other neurochemicals ay a part in the placebo effect. Endorphins may be the dy's natural pain relievers. In 2001, though, a scientific idy found that placebos have little or no actual effect.

Placebos are used in research to help determine the ectiveness of new drugs. One group of patients re- ives the drug. Another group of patients with the me illness, called the *control group,* gets a placebo. e placebo and the drug look alike. Neither the pa- nts nor the doctors know which is the placebo and hich is the drug. Placebo groups are important in stud- of diseases with symptoms that worsen or improve er time, such as arthritis or depression. Researchers rn if a new drug is effective by comparing the effects the drug with those of the placebo.

Physicians have also used placebo groups to test the ectiveness of some surgical operations, such as hroscopic knee surgery to treat osteoarthritis. In such ts, a number of patients are sent to the operating om and put to sleep. A surgeon makes an incision in the patients, but only half actually have the surgical eration. Patients and caregivers are not told if real rgery was performed until after the study is complet- . Melanie Johns Cupp

acenta, *pluh SEHN tuh,* is a disk-shaped organ that velops in pregnant women. The placenta provides the born baby with food and oxygen and carries away the by's waste products. The organ also produces chemi- ls called *hormones,* which maintain the pregnancy d help regulate the baby's development.

The placenta consists of tissue from both the mother d the embryo. After the first week of pregnancy, the ibryo fastens itself to the wall of the *uterus,* the organ which the baby develops. The placenta forms as the erine lining is penetrated and broken down by col- ns of cells from the *chorion,* the baglike covering it encloses the embryo. Inside the columns are blood ssels that branch into tiny, fingerlike projections led *villi.* The villi, which contain the baby's blood, are rrounded by the mother's blood. The blood of the by and of the mother do not mix.

Food and oxygen from the mother's blood pass through the thin walls of the villi and enter the baby's blood through a vein in the *umbilical cord,* a flexible tube connecting the baby to the placenta. Waste prod- ucts from the baby are carried through arteries in the umbilical cord and pass through the villi. The mother's circulatory system then gets rid of these wastes.

The placenta expands in size until about 20 weeks. At that time, it covers about half of the internal surface of the uterus. After 20 weeks, the placenta becomes thicker but not wider. At the end of a nine-month pregnancy, it is about 6 to 8 inches (15 to 20 centimeters) in diameter and about 1 to 1 $\frac{1}{4}$ inches (2.5 to 3.0 centimeters) thick. It weighs about 14 to 21 ounces (400 to 600 grams).

Minutes after the baby is born, the placenta separates from the uterus. Powerful contractions of the uterus ex- pel the placenta, also called the *afterbirth,* from the mother's body. Lois Kazmier Halstead

Placentia, *pluh SEHN shuh,* Newfoundland and Labra- dor (pop. 4,426), is the site of an early French settlement in North America. It lies in the southeast corner of the is- land of Newfoundland, about 63 miles (101 kilometers) southwest of the provincial capital, St. John's. See **New- foundland and Labrador** (political map). Placentia was the French headquarters from 1662 until Newfoundland was given to Britain (now the United Kingdom) by the Peace of Utrecht in 1713. The town has ruins of the old French forts, and French and Basque tombstones dating from the 1600's. It is a popular tourist resort with excel- lent salmon fishing in nearby streams. Simon M. Evans

Placid, Lake. See **Lake Placid**.

Plagiarism, *PLAY juh rihz uhm,* is the act of present- ing another person's literary, artistic, or musical work as one's own. For example, a student who copies from ref- erence books has committed plagiarism. A work need not be identical to the original to be a plagiarism. But it must be so similar that it has obviously been copied.

Plagiarism is regarded as unethical. The copyright laws of many nations make plagiarism and other unau- thorized copying a crime punishable by fine or impris- onment. In addition, the creator of a copyrighted work may sue anyone who plagiarizes it. Educational institu- tions prohibit plagiarism, and a student who plagiarizes will be subject to disciplinary penalties.

Plagiarism does not include the adoption of character types, general plots, or other ideas from existing works. Nearly all writers and artists do such borrowing, but they express the ideas in new ways. The great English playwright William Shakespeare took most of his plots from published historical and literary works. But he changed the borrowed materials into works that were uniquely his own. Plagiarism also does not normally in- clude the copying allowed under the *fair use principle* of the copyright law. This principle permits limited re- production of another person's work without permis- sion for such purposes as teaching, research, news re- porting, or criticism. In most cases, the author of the original work should be named. Kent Dunlap

Plague, *playg,* is both the name of a serious infectious disease caused by the bacterium *Yersinia pestis* and a term used to describe epidemics generally. This article discusses the disease caused by *Y. pestis.* The bacterium

is named after French scientist Alexandre Yersin, who first identified it in Hong Kong in 1894. Since early times, epidemics of plague have killed hundreds of millions of people. Plague bacteria infect rodents, such as rats, ground squirrels, and prairie dogs. The bites of fleas transmit the germs from rodent to rodent and from rodents to human beings or pets.

Forms of plague. The three main forms of plague are (1) bubonic, (2) septicemic, and (3) pneumonic. Bubonic plague is by far the most common form. It results when a person is bitten by an infected flea. The plague bacteria invade lymph nodes near the bite, causing painful swellings called *buboes.* The buboes usually appear in the legs, neck, armpits, or groin. Plague is called septicemic when the bacteria infect the bloodstream and spread to other parts of the body. Pneumonic plague occurs when the bacteria infect the lungs. It is the most dangerous form because patients can spread the bacteria easily to others by coughing.

Symptoms of plague develop from one to eight days after infection. Symptoms include high fever, rapid pulse, headache, body aches, and weakness. Antibiotics are effective against plague if given soon after infection. Unless treated, plague patients deteriorate rapidly, and most die within five days.

History of plague. Medical historians have identified many epidemics of plague based on written descriptions and paintings of people with buboes. Perhaps the earliest such description is the *plague of Ashdod,* which occurred about 1000 B.C. and is described in the Bible.

In the mid-500's A.D., an epidemic that was almost certainly plague struck the Byzantine Empire and spread from the Black Sea across Europe, killing as much as half the population of Constantinople (now Istanbul, Turkey). Historians later called this the first *pandemic* (worldwide occurrence) of plague.

A second pandemic, often called the "Black Death," swept across Asia and Europe in the mid-1300's. It probably began in Central Asia early in the 1300's. Trading ships carried infected rats west to the Mediterranean Sea. From there, plague spread through most of Europe. By 1400, it had killed 20 million to 30 million people.

A third pandemic began in China in the mid-1800's. Over the next 75 years, plague spread to every inhabited continent and killed up to 20 million people. Plague reached San Francisco in 1899, and later other ports, via ships. Health professionals eventually controlled plague in U.S. cities, but plague-infected wild rodents spread from California to many western states, where several cases still occur each year.

Today, plague occurs occasionally throughout the world, with 1,000 to 2,000 cases reported annually. The bacteria flourish mainly in rural areas, including the western United States, central and southern Asia, Afric South America, and nations bordering the Caspian Se Since the 1990's, public health experts have become in creasingly concerned about plague because it has potential for use in biological weapons. D. Peter Drotman

Plain is a broad, nearly level stretch of land with no abrupt changes in elevation. Plains are generally lower than the land around them. They may be found along a coast or inland. Coastal plains usually rise from sea lev until they meet higher land forms, such as mountains plateaus. Inland plains may be found at high altitudes.

Climate controls plant life on plains. Thick forests us ally thrive on plains in humid climates. Grasslands cov fairly dry plains, such as the Great Plains in the United States. Plains are usually well populated because the soils and terrain are good for farming and because roads and railroads are easy to build on level land.

Coastal plain is a stretch of lowland along a seacoas which slopes gently toward the sea. In many cases, su a plain may be an elevated part of the ocean floor. Soli materials carried off by rivers or waves form other coastal plains. These materials are deposited along the shore, extending the coast seaward.

Flood plain is the floor of a river valley, beyond the riverbed. A flood plain is formed of mud, sand, and sil left by the overflow of a river. These materials are carried off by the river as it *erodes* (wears away) the land upstream. A river in flood can carry a large amount of eroded material, which the overflow waters deposit onto the flood plain. David S. McArthur

Kinds of plains

This illustration shows some of the chief kinds of plains. *Coastal plains* are lowlands that slope gently toward the sea. *Inland plains* occur in the interior of a land mass, usually at higher altitudes than coastal plains. *Flood plains* are formed of mud, sand, and silt left by the overflow of a river.

Eric Gravé, Science Photo Library

n enlarged view of a planarian shows the worm's "eyes," hich do not form images as true eyes do. The planarian's feed- g tube, *center,* is on the underside of its extremely thin body.

hese eyes can detect light and dark, but they cannot orm images as the eyes of many other animals do.

Planarians feed on other small animals or on dead an- nal matter. Grooves or pits on each side of the head an sense food.

Planarians lay fertilized eggs in cocoons. The young orms that hatch look like small adult worms. Many pla- arians can also reproduce by simply dividing into ieces. Each piece of the worm then can develop into a omplete new adult. Planarians have remarkable abilities) *regenerate* (regrow) any lost or damaged parts of ieir bodies. Seth Tyler

Scientific classification. Planarians belong to the order Tri- adida of the class Turbellaria in the phylum Platyhelminthes.

lanck, *plahngk,* **Max Karl Ernst Ludwig** (1858- 947), was a German theoretical physicist who concen- ated on the study of thermodynamics. He was con- erned with the phenomena of absorption and emission f heat and other kinds of radiant energy. In 1900, Planck riginated the *quantum theory* when he proposed his w of radiation. This new theory revolutionized the field f physics. In 1918, Planck was awarded the Nobel Prize ır physics.

The major concept involved in Planck's theory was ıat an object that completely absorbs radiant energy, ıown to scientists as a *black body,* can only absorb or nit energy in tiny irreducible bits called *quanta.* The ıergy of each quantum is measured by multiplying the equency of the radiant energy, ν, by a universal con- ant, *h.* The constant is known as *Planck's constant.* hus, energy *(E)* equals *hν*. For example, a red flame nits less energy—that is, it is cooler—than a blue flame ecause red light has a lower frequency than blue light.

Planck's concept of quanta disagreed with former leas about energy. Scientists had thought that energy owed continuously. This view, however, could not ex- lain the absorption and emission of energy by matter. anck's theory accounted for this phenomenon.

In 1905, the German-born physicist Albert Einstein in- ependently introduced the concept of light quanta (see nstein, Albert). In 1913, Danish physicist Niels Bohr in- oduced quantum ideas into atomic theory and origi- ıted the modern theory of atomic structure (see **Bohr,** iels).

Planck was born in Kiel, Germany. He studied at the ıiversities of Munich and Berlin, and taught physics at e universities of Munich, Kiel, and Berlin.

Planet

Planet is a large, round heavenly body that orbits a star and shines with light reflected from the star. We know of nine planets that orbit the sun in our solar system. Since 1992, astronomers have also discovered many planets orbiting other stars.

All but two of the planets in our solar system have smaller objects revolving around them called *satellites* or *moons.* Our solar system also contains thousands of smaller bodies known as *asteroids.* The asteroids are often called minor planets, and the term *major planet* is used to distinguish the nine planets from the asteroids. The remainder of this article uses *planet* to mean *major planet.*

The usual order of the planets in our solar system, outward from the sun, is Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto. To help remember the order, some people use the phrase *My Very Educated Mother Just Sent Us Nine Pizzas* as a memory aid. The initial letters of the words in that phrase match the initial letters of the planet names.

Pluto is not always the farthest planet from the sun, however. Its orbit is such a long oval that Pluto moves inside the path of Neptune for about 20 years every 248 years. One such 20-year period lasted from Jan. 23, 1979, to Feb. 11, 1999.

The planets in our solar system can be divided into two groups, except for Pluto. The innermost four planets—Mercury, Venus, Earth, and Mars—are small, rocky worlds. They are called the *terrestrial* (earthlike) planets, from the Latin word for Earth, *terra.* Earth is the largest terrestrial planet. The other earthlike planets have from 38 percent to 95 percent of Earth's diameter and from 5.6 percent to 81 percent of Earth's *mass* (total quantity of matter).

The next four planets—Jupiter, Saturn, Uranus, and Neptune—are called *gas giants* or *Jovian* (Jupiterlike) *planets.* They have gaseous atmospheres and no solid surfaces. All four Jovian planets consist mainly of hydrogen and helium. Smaller amounts of other materials also occur, including traces of ammonia and methane in their atmospheres. They range from 3.9 times to 11.2 times Earth's diameter and from 15 times to 318 times Earth's mass. Jupiter, Saturn, and Neptune give off more energy than they receive from the sun. Most of this extra energy takes the form of *infrared* radiation, which is felt as heat, instead of visible light. Scientists think the source of some of the energy is probably the slow compression of the planets by their own gravity.

The ninth planet, Pluto, is only 18 percent the diameter of Earth and $\frac{1}{500}$ of its mass. As a small, rocky planet with a larger orbit than the gas giants, it does not fit in either group. Some astronomers think that Pluto may not be a major planet at all.

Observing the planets

People have known the inner six planets of our solar system for thousands of years because they are visible

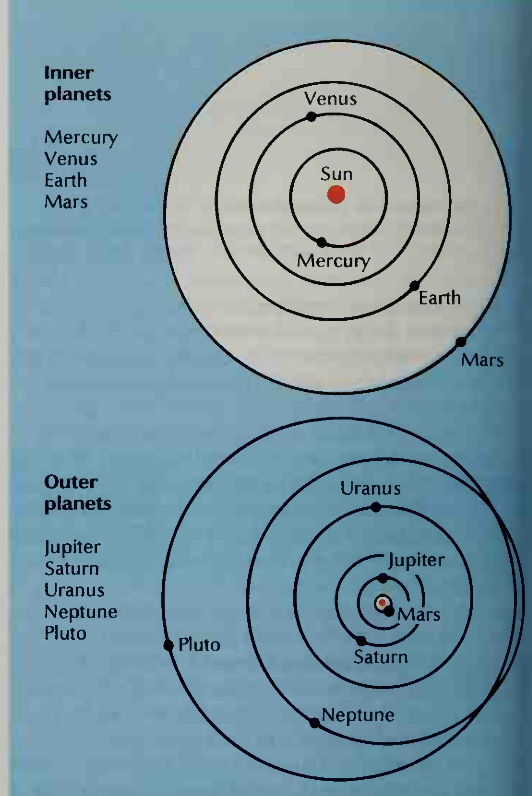
Jay M. Pasachoff, the contributor of this article, is Field Memorial Professor of Astronomy and Director of the Hopkins Observatory at Williams College.

from Earth without a telescope. The outermost three planets—Uranus, Neptune, and Pluto—were discovered by astronomers, beginning in the 1780's. All three can be seen from Earth with a telescope.

To the unaided eye, the planets look much like the background stars in the night sky. However, the planets move slightly from night to night in relation to the stars. The name *planet* comes from a Greek word meaning *to wander.* The planets and the moon almost always follow the same apparent path through the sky. This path, known as the *zodiac,* is about 16° wide. At its center is the *ecliptic,* the apparent path of the sun. If you see a bright object near the ecliptic at night or near sunrise or sunset, it is most likely a planet. You can even see the brightest planets in the daytime, if you know where to look.

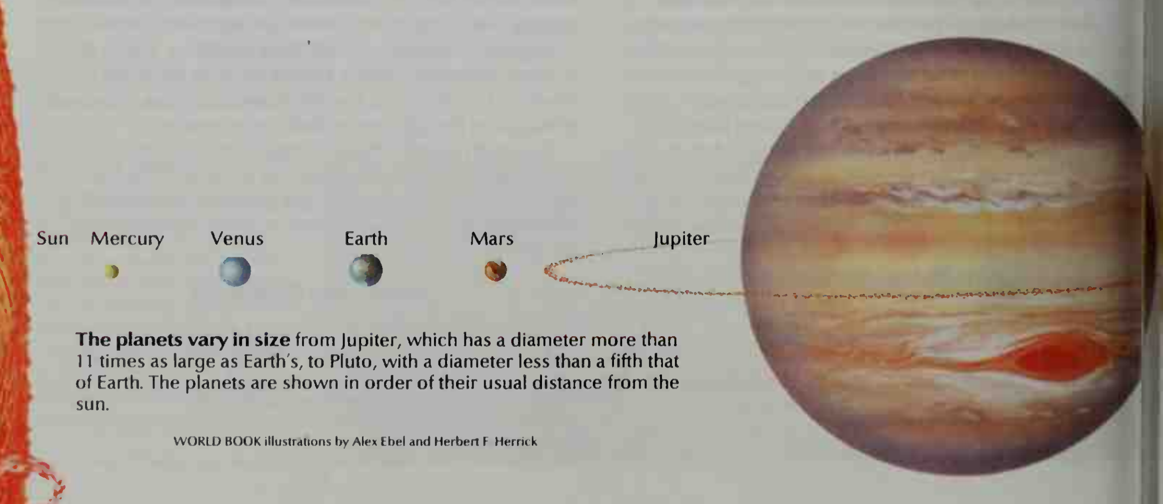
Planets and stars also differ in the steadiness of their light when viewed from Earth's surface. Planets shine with a steady light, but stars seem to twinkle.

The twinkling is due to the moving layers of air that surround Earth. Stars are so far away that they are mere points of light in the sky, even when viewed through a telescope. The atmosphere bends the starlight passing through it. As small regions of the atmosphere move about, the points of light seem to dance and change in brightness.



Planets, which are much closer, look like tiny disks through a telescope. The atmosphere scatters light from different points on a planet's disk. However, enough light always arrives from a sufficient number of points to provide a steady appearance.

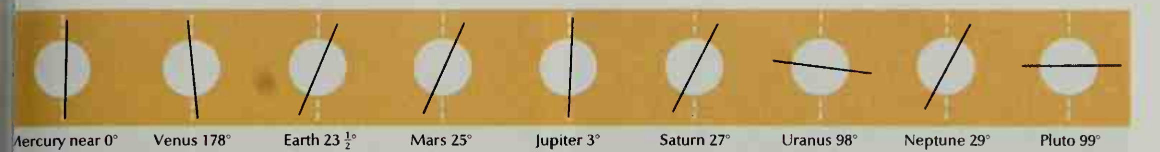
How planets move



Planets move in two main ways. They travel around their parent star in paths called *orbits.* As each planet orbits its star, it also rotates on its *axis,* an imaginary line through its center.

Orbits. Viewed from Earth's surface, the planets of the solar system and the stars appear to move around Earth. They rise in the east and set in the west each night. Most of the time, the planets move westward across the sky slightly more slowly than the stars do. As a result, the planets seem to drift eastward relative to the background stars. This motion is called *prograde.* For a while each year, however, the planets seem to reverse their direction. This backward motion is called *retrograde.*

In ancient times, most scientists thought that the moon, sun, planets, and stars actually moved around Earth. One puzzle that ancient scientists struggled to explain was the annual retrograde motion of the planets. In about A.D. 150, the Greek astronomer Ptolemy developed a theory that the planets orbited in small circles, which in turn orbited Earth in larger circles. Ptolemy

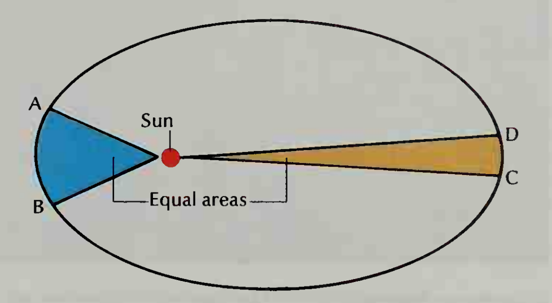


The orbits of the planets around the sun are shown here. Two diagrams are needed because the orbits of the outer planets would extend off the page if they were drawn to the same scale as those of the inner planets.

The planets vary in size from Jupiter, which has a diameter more than 11 times as large as Earth's, to Pluto, with a diameter less than a fifth that of Earth. The planets are shown in order of their usual distance from the sun.

WORLD BOOK illustrations by Alex Ebel and Herbert F. Herrick

The axes of the planets, represented by the solid lines, are imaginary lines around which the planets rotate. A planet's axis is not perpendicular to the path of the planet's orbit around the sun. It is at an angle from the perpendicular position indicated by the broken line.



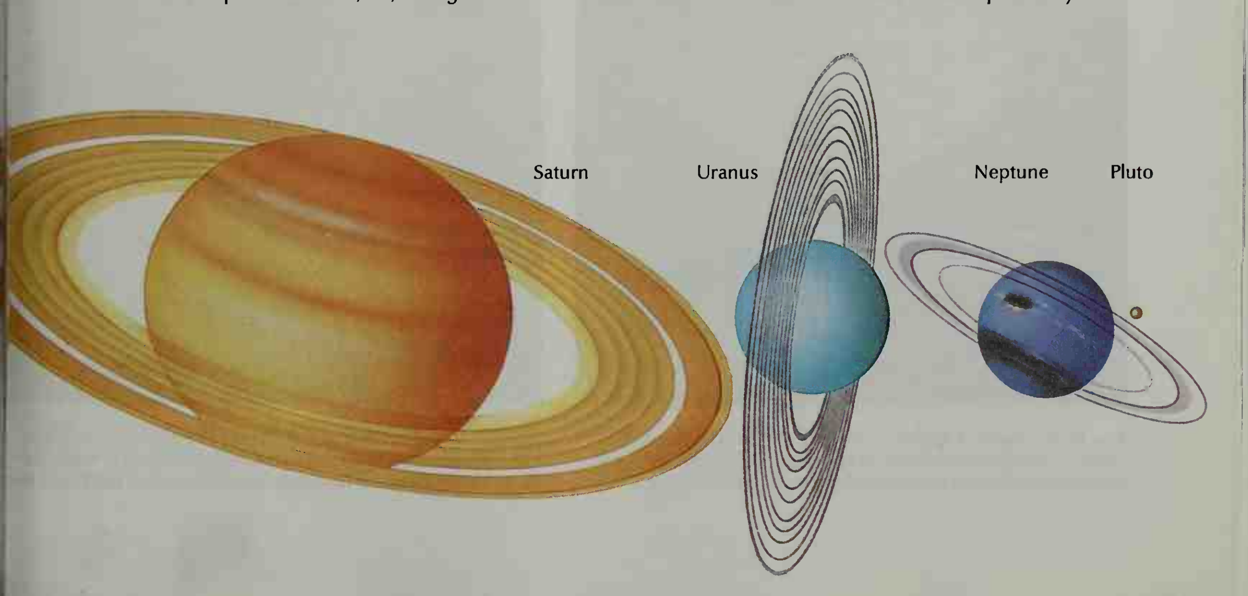
thought that retrograde motion was caused by a planet moving on its small circle in an opposite direction from the motion of the small circle around the big circle.

In 1543, the Polish astronomer Nicolaus Copernicus showed that the sun is the center of the orbits of the planets. Our term *solar system* is based on Copernicus's discovery. Copernicus realized that retrograde motion occurs because Earth moves faster in its orbit than the planets that are farther from the sun. The planets that are closer to the sun move faster in their orbits than Earth travels in its orbit. Retrograde motion occurs whenever Earth passes an outer planet traveling around the sun or an inner planet passes Earth.

In the 1600's, the German astronomer Johannes Kepler used observations of Mars by the Danish astronomer Tycho Brahe to figure out three laws of planetary motion. Although Kepler developed his laws for the planets of our solar system, astronomers have since realized that Kepler's laws are valid for all heavenly bodies that orbit other bodies.

Kepler's first law says that planets move in *elliptical* (oval-shaped) orbits around their parent star—in our solar system, the sun. An *ellipse* is a closed curve formed around two fixed points called *foci.* The ellipse is formed by the path of a point moving so that the sum of its distances from the two foci remains the same. The orbital paths of the planets form ellipses, with the parent star at one focus of the ellipse. Before Kepler, scientists had assumed that the planets moved in circular orbits.

Kepler's second law says that an imaginary line joining the parent star to its planet sweeps across equal areas of space in equal amounts of time. When a planet is close to its star, it moves relatively rapidly in its orbit. The line therefore sweeps out a short, fat, trianglelike



Kepler's second law shows how a planet covers equal areas of its orbit in equal lengths of time. The planet travels at a higher speed near the sun, from *A* to *B*, than far from the sun, *C* to *D.*

figure. When the planet is farther from its star, it moves relatively slowly. In this case, the line sweeps out a long, thin figure that resembles a triangle. But the two figures have equal areas.

Kepler's third law says that a planet's *period* (the time it takes to complete an orbit around its star) depends on its average distance from the star. The law says that the square of the planet's period—that is, the period multiplied by itself—is proportional to the cube of the planet's average distance from its star—the distance multiplied by itself twice—for all planets in a solar system.

The English scientist, astronomer, and mathematician Isaac Newton presented his theory of gravity and explained why Kepler's laws work in a treatise published in 1687. In the treatise, Newton showed how his expanded version of Kepler's third law could be used to find the mass of the sun or the mass of any other object around which things orbit. Using Newton's explanation, astronomers can determine the mass of a planet by

NASA/JPL/MSSS

A canyon on Mars is Earthlike in appearance. However, numerous craters produced by the impact of meteorites give the surface near the edge of the canyon a pitted, unearthly look.

NASA/JPL

The Great Red Spot of Jupiter is one of the most spectacular features in the solar system. This swirling mass of gas, which resembles a hurricane, is about three times as wide as Earth.

studying the period of its moon or moons and their distance from the planet.

Rotation. Planets rotate at different rates. One day is defined as how long it takes Earth to rotate once. Jupiter and Saturn spin much faster, in only about 10 hours. Venus rotates much slower, in about 243 earth-days.

Most planets rotate in the same direction in which they revolve around the sun, with their axis of rotation standing upright from their orbital path. A law of physics holds that such rotation does not change by itself. So astronomers think that the solar system formed out of a cloud of gas and dust that was already spinning.

Uranus and Pluto are tipped on their sides, however, so that their axes lie nearly level with their paths around the sun. Venus is tipped all the way over. Its axis is almost completely upright, but the planet rotates in the direction opposite from the direction of its revolution around the sun. Most astronomers think that some other objects in the solar system must have collided with Uranus, Pluto, and Venus and tipped them.

The planets of our solar system

Astronomers measure distances within the solar system in *astronomical units* (AU). One astronomical unit is the average distance between Earth and the sun, which is about 93 million miles (150 million kilometers). The inner planets have orbits whose diameters are 0.4, 0.7, 1.0, and 1.5 AU, respectively. The orbits of the gas giants are

NASA/JPL

The blue clouds of Neptune are mostly frozen methane, the main chemical in natural gas—a fuel used for heating and cooking on Earth. The other object shown is Neptune's moon Triton.

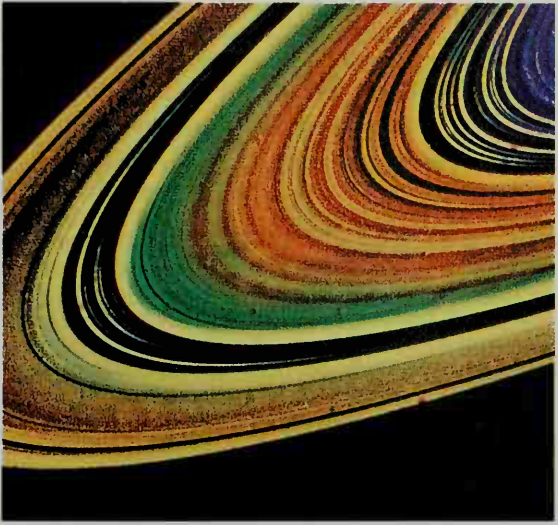
NASA/JPL

A river of lava on Venus split in two as it flowed from left to right, producing a delta like those made by rivers of water on Earth. Venus's surface has many long channels of hardened lava

uch larger: 5, 10, 20, and 30 AU, respectively. Because their different distances from the sun, the tempera-re, surface features, and other conditions on the plan-s vary widely.

Mercury, the innermost planet, has no moon and al-ost no atmosphere. It orbits so close to the sun that mperatures on its surface can climb as high as 800 °F 30 °C). But some regions near the planet's poles may always in shadow, and astronomers speculate that ater or ice may remain there. No spacecraft has visited ercury since the 1970's, when Mariner 10 photo-aphed about half the planet's surface at close range.

Venus is known as Earth's twin because it resembles rth in size and mass, though it has no moon. Venus s a dense atmosphere that consists primarily of car-n dioxide. The pressure of the atmosphere on Venus's rface is 90 times that of Earth's atmosphere. Venus's ick atmosphere traps energy from the sun, raising the rface temperature on Venus to about 860 °F (460 °C), t enough to melt lead. This trapping of heat is known the *greenhouse effect.* Scientists have warned that a nilar process on Earth is causing permanent global arming. Several spacecraft have orbited or landed on enus. In the 1990's, the Magellan spacecraft used dar—radio waves bounced off the planet—to map enus in detail.



Earth, our home planet, has an atmosphere that is ostly nitrogen with some oxygen. Earth has oceans of uid water and continents that rise above sea level. any measuring devices on the surface and in space onitor conditions on our planet. In 1998, the National eronautics and Space Administration (NASA) launched e first of a series of satellites called the Earth Observ-g System (EOS). The EOS satellites will carry remote-nsing instruments to measure climate changes and her conditions on Earth's surface.

Mars is known as the red planet because of its red-sh-brown appearance, caused by rusty dust on the artian surface. Mars is a cold, dry world with a thin at-osphere. The *atmospheric pressure* (pressure exerted the weight of the gases in the atmosphere) on the artian surface is less than 1 percent the atmospheric essure on Earth. This low surface pressure has en-led most of the water that Mars may once have had to cape into space.

The surface of Mars has giant volcanoes, a huge sys-m of canyons, and stream beds that look as if water wed through them in the past. Mars has two tiny oons, Phobos and Deimos. Many spacecraft have land-l on or orbited Mars.

Jupiter, the largest planet in our solar system, has ore mass than the other planets combined. Like the her Jovian planets, it has gaseous outer layers and may ve a rocky core. A huge storm system called the Great ed Spot in Jupiter's atmosphere is larger than Earth d has raged for hundreds of years.

Jupiter's four largest moons—Io, Europa, Ganymede, d Callisto—are larger than Pluto, and Ganymede is so bigger than Mercury. Circling Jupiter's equator are ree thin rings, consisting mostly of dust particles. A ir of Voyager spacecraft flew by Jupiter in 1979 and nt back close-up pictures. In 1995, the Galileo space-aft dropped a probe into Jupiter's atmosphere and ent into orbit around the planet and its moons.

NASA/JPL

The rings of Saturn consist of billions of pieces of ice, ranging in size from particles the size of dust grains to chunks over 10 feet (3 meters) wide. The rings are shown here in false color.

Saturn, another giant planet, has a magnificent set of gleaming rings. Its gaseous atmosphere is not as color-ful as Jupiter's, however. One reason Saturn is relatively drab is that its hazy upper atmosphere makes the cloud patterns below difficult to see. Another reason is that Saturn is farther than Jupiter from the sun. Because of the difference in distance, Saturn is colder than Jupiter. Due to the temperature difference, the kinds of chemi-cal reactions that color Jupiter's atmosphere occur too slowly to do the same on Saturn.

Saturn's moon Titan is larger than Pluto and Mercury. Titan has a thick atmosphere of nitrogen and methane. In 1980 and 1981, the Voyager 2 spacecraft sent back close-up views of Saturn and its rings and moons.

The Cassini spacecraft will orbit Saturn in 2004. It will also drop a small probe into Titan's atmosphere.

Uranus was the first planet discovered with a tele-scope. German-born English astronomer William Her-schel found it in 1781. He at first thought he had discov-ered a comet. Almost 200 years later, scientists detected 10 narrow rings around Uranus when the planet moved in front of a star and the rings became visible. Voyager 2 studied Uranus and its rings and moons close-up in 1986.

Neptune was first observed in 1846 by German as-tronomer Johann G. Galle after other astronomers pre-dicted its position by studying how it affected Uranus's orbit. In 1989, Voyager 2 found that Neptune had a storm system called the Great Dark Spot, similar to Jupiter's Great Red Spot. But five years later, in 1994, the Hubble Space Telescope found that the Great Dark Spot had vanished. Neptune has four narrow rings, one of which has clumps of matter. Neptune's moon Triton is one of the largest in the solar system and has volcanoes that emit plumes of frozen nitrogen.

Pluto. Tiny, distant Pluto has been difficult to study because it is so far from Earth. The American astrono-mer Clyde W. Tombaugh discovered Pluto in 1930. Only in 1978, when astronomers discovered a moon orbiting

Pluto, could they determine the planet's mass. They found that Pluto was much less massive than expected. The Hubble Space Telescope found a dozen areas of contrasting light and dark on Pluto.

Planets in other solar systems

How planets are detected. Even with the most advanced telescopes, astronomers cannot see planets orbiting other stars directly. The planets shine only by reflected light and are hidden by the brilliance of their parent stars. The planets and their stars are also much farther away than our sun. The nearest star is 4.2 light-years away, compared to 8 light-minutes for the sun. One *light-year* is the distance that light travels in one year—about 5.88 trillion miles (9.46 trillion kilometers). Thus, it takes light 4.2 years to reach Earth from the nearest star beyond the sun and only 8 minutes to reach Earth from the sun.

Astronomers know of more than 50 stars other than the sun that have planets. Scientists detected those planets from tiny changes in the stars' movement and tiny decreases in the amount of light coming from the stars.

The changes in a star's movement are caused by the slight pull of the planet's gravity on its parent star. To find new planets, astronomers use a technique called *spectroscopy,* which breaks down the light from stars into its component rainbow of colors. The scientists look for places in the rainbow where colors are missing. At these places, dark lines known as *spectral lines* cross the rainbow. The spectral lines change their location in the rainbow slightly as a star is pulled by the gravity of an orbiting planet toward and away from Earth. These apparent changes in a star's light as the star moves are due to a phenomenon known as the *Doppler effect.* The changes not only show that a planet is present but also indicate how much mass it has.

The amount of light coming from the star decreases when the planet passes in front of the star. The planet blocks some of the starlight, dimming the star.

The first discoveries. Astronomers announced the discovery of the first planets around a star other than our sun in 1992. The star is a pulsar named PSR B1257+12 in the constellation Virgo. *Pulsars* are dead stars that have collapsed until they are only about 12 miles (20 kilometers) across. They spin rapidly on their axes, sending out radio waves that arrive on Earth as pulses of radio energy. Some pulsars spin hundreds of times each second. If a pulsar has a planet, the planet pulls the star to and fro slightly as it orbits. These pulls cause slight variations in the radio pulses. From measurements of these variations, the Polish-born American astronomer Alexander Wolszczan and American Dale A Frail discovered three planets in orbit around PSR B1257+12. The star emits such strong X rays, however, that no life could survive on its planets.

Astronomers using the spectroscopic technique soo began to find planets around stars more like the sun. In 1995, Swiss astronomers Michel Mayor and Didier Queloz found the first planet orbiting a sunlike star, 51 Pegasi, in the constellation Pegasus. American astronomers Geoffrey W. Marcy and R. Paul Butler confirmed the discovery and found planets of their own around other stars. In 1999, astronomers announced the first discovery of a multiple-planet system belonging to a sunlike star. They determined that three planets orbit th star Upsilon Andromedae, which is 44 light-years from Earth in the constellation Andromeda.

Also in 1999, American astronomer Gregory W. Henr first detected a dimming of starlight due to the presenc of a planet. The star that Henry observed is known as H 209458, and it is located in Pegasus. Henry measured th star's brightness at the request of Marcy, Butler, and American astronomer Steven S. Vogt, who had previously used the spectroscopic technique to identify this star as a parent of a planet.

Some stars have a planet orbiting them at a distance

The planets at a glance*

	Mercury ☿	Venus ♀	Earth ⊕	Mars ♂
Average distance from the sun	35,980,000 mi (57,900,000 km)	67,230,000 mi (108,200,000 km)	92,960,000 mi (149,600,000 km)	141,620,000 mi (227,920,000 km)

*Many of these figures are approximations or obtained by scientific calculations.

which living things could exist. Most scientists consid- liquid water essential for life, so a region that is nei- er too hot nor too cold for liquid water is known as a *ıbitable zone.* Although astronomers have found stars ith planets in their habitable zones, all the planets und so far are probably gaseous with no solid surface. ıt they may have solid moons.

In 2001, Marcy announced the discovery of a solar stem containing an extremely unusual object. That ob- ct and an ordinary planet orbit the star HD 168443, hich is 123 light-years away in the constellation Ser- ens. The object is so unusual because of its mass. It is least 17 times as massive as Jupiter.

Astronomers are not yet sure how to classify the ob- ct. They had not thought that a planet could be as mas- ve as the object is. Before this discovery, the only ıown heavenly bodies of such mass were dim objects lled *brown dwarfs.* But brown dwarfs form by means the same process that forms stars, not planets.

Astronomers were surprised to find that other solar stems have huge, gaseous planets in close orbits. In ır own solar system, the inner planets are rocky and nall, and only the outer planets, except for Pluto, are ıge and gassy. But several newly discovered planets ıve at least as much mass as Jupiter, the largest planet our solar system. Unlike Jupiter, however, these mas- ve planets race around their stars in only a few weeks. epler's third law says that for a planet to complete its bit so quickly, it must be close to its parent star. Sever- of these giant planets, therefore, must travel around eir stars even closer than our innermost planet, Mer- ıry, orbits our sun. Such close orbits would make their ırfaces too hot to support life as we know it.

Some newly discovered planets follow unusual orbits. ıost planets travel around their stars on nearly circular ıths, as the planets in our solar system do. But a planet ound the star 16 Cygni B follows an extremely elliptical bit. It travels farther from its star than Mars does from our sun, and then draws closer to the star than Venus does to our sun. If a planet in our solar system traveled in such an extreme oval, its gravity would disrupt the orbits of the other planets and toss them out of their paths.

How the planets formed

Astronomers have developed a theory about how our solar system formed that explains why it has small, rocky planets close to the sun and big, gaseous ones farther away. Astronomers believe our solar system formed about 4.6 billion years ago from a giant, rotating cloud of gas and dust called the *solar nebula.* Gravity pulled together a portion of gas and dust at the center of the nebula that was denser than the rest. The material accumulated into a dense, spinning clump that eventually formed our sun.

The remaining gas and dust flattened into a disk called a *protoplanetary disk* swirling around the sun. Protoplanetary disks around distant stars were first observed through telescopes in 1983. Rocky particles within the disk collided and stuck together, forming bodies called *planetesimals.* Planetesimals later combined to form the planets. At the distances of the outer planets, gases froze into ice, creating huge balls of frozen gas that formed the Jovian planets.

Hot gases and electrically charged particles flow from our sun constantly, forming a stream called the *solar wind.* The solar wind was stronger at first than it is today. The early solar wind drove the light elements—hydrogen and helium—away from the inner planets like Earth. But the stronger gravity of the giant outer planets held on to more of the planets' hydrogen and helium, and the solar wind was weaker there. So these outer planets kept most of their light elements and wound up with much more mass than Earth.

Astronomers developed these theories when they thought that rocky planets always orbited close to the parent star and giant planets orbited farther away from

it. But the "rule" was based only on our own solar system. Now that astronomers have learned something about other solar systems, they have devised new theories. Some scientists have suggested that the giant planets in other solar systems may have formed far from their parent stars and later moved in closer.

The Rose Center for Earth and Space in New York City hous the huge hollow sphere that makes up the Hayden Planetarium.

Planetarium is an educational device that shows the locations and movements of planets and other objects in the universe. A room or building that houses such a device is also called a planetarium. Each year, about 90 million people visit such places throughout the world.

Early planetariums were either (1) movable pictures c the starry sky painted on the inside of a sphere or dom or (2) mechanical models of the solar system. A modern planetarium projects images of the sun, moon, planets, stars, and other objects onto the inside of a dome-shaped screen. Until the early 1980's, planetariums could project the night sky as seen only from Earth. Since then, many planetariums have used computers to *simulate* (represent) the view from other locations.

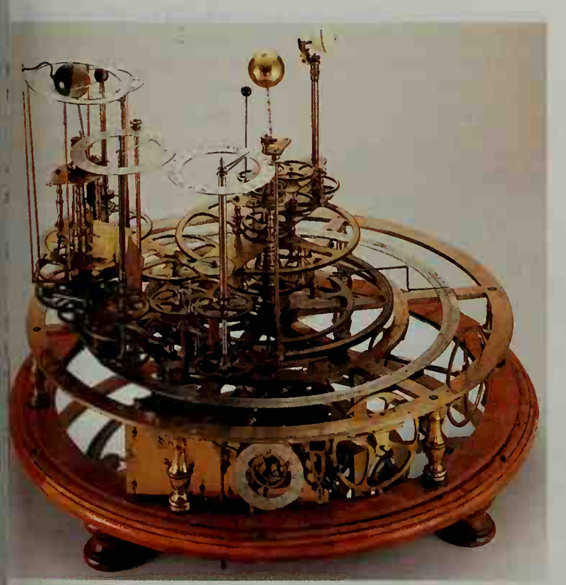
Early planetariums

One of the first planetariums with a movable paintinc of the starry sky was known as the Gottorp Globe. That device was made in the mid-1600's in what is now Germany. The main part of the planetarium was a hollow copper sphere 10.2 feet (3.1 meters) in diameter. Inside were a table and a curved bench for 12 people. Painted on the sphere's inner surface were pictures of the constellations. The stars were copper nailheads coated wit gold. Light from a central oil lamp made them shine. A copper globe representing Earth lay on the table.

The hollow sphere could rotate relative to the bench The sphere's axis of rotation was an imaginary line that extended from the poles of the copper globe to the sky in the painting. Thus, the sphere's rotation simulated th apparent motion of the stars as Earth rotates on its axis.

Beginning in the late 1600's, clockmakers in Europe built small model planetariums that simulated the motion of the planets around the sun. A ball at the center represented the sun. Extending from the center were rods that held smaller spheres representing the planets By cranking or winding up the model, a person could move its miniature planets around the sun. A system of gears made the planets move at fairly accurate speeds relative to one another. Some models also showed how

© Dennis Finnin, AMNH



A projector at the Hayden Planetarium in New York City creates images of stars and a cloud of dust and gas on the planetarium dome. The projector can produce images of over 9,000 stars.

ıoons revolved around their planets.

Early in the 1700's, a model planetarium became ıown as an *orrery*—named for the Earl of Orrery, an ish nobleman who had one made in 1712. The manuıcture of small orreries continues to this day. Many scince teachers use them because they make the moveıents of the planets easy to understand.

The invention of electric lights and motors in the late 800's made it practical to build large orreries. The first of these was installed in the Deutsches Museum in Munich, Germany, in the early 1920's. At the center of a circular room was a large lighted globe that represented the sun. Smaller lighted globes represented the planets. The smaller globes were suspended from the ceiling by rods. The rods were attached to motor-driven cars that traveled along "orbital" tracks around the big globe.

Beneath the globe representing Earth was a small, motor-driven platform that an individual could ride. As the orrery ran, a rider could see a simulation of the planets' revolution around the sun from Earth's perspective. Similar versions of this kind of orrery were later built at the Hayden Planetarium in New York City and at the University of North Carolina at Chapel Hill.

© Adler Planetarium & Astronomy Museum

n orrery built in about 1780 used a complex system of gears to rive the planets of a model solar system in a way that imitated ıe revolution of the actual planets around the sun.

Modern planetariums

Mechanical projectors. In 1925, the German firm Carl Zeiss permanently installed the first modern planetarium at the Deutsches Museum in Munich. This device, called the Mark I, was mounted inside a dome 32 feet (10 meters) in diameter. People sat in chairs under the dome and looked up at images of stars, planets, the sun, and the moon.

A hollow metal sphere known as a *star ball* used 31 lenses to display images of 4,500 stars on the dome. The ball could rotate to simulate Earth's rotation. Seven additional projectors attached to the ball created images of the sun, the moon, Mercury, Venus, Mars, Jupiter, and Saturn. The seven projectors moved relative to the star ball, thereby simulating the motion of the planets relative to the stars.

The star ball was 20 inches (50 centimeters) in diameter. Light for the images came from a bright electric lamp in the center of the ball. The 31 lenses surrounded the lamp. Mounted behind each lens was a disk called a *star plate* that acted somewhat like a photographic slide.

Light from the lamp passed through holes in the plate. Each hole represented a star; bigger holes simulated brighter stars.

Each projector's lens focused onto the dome the light that passed through the holes in its star plate. Each plate represented a little more than 3 percent of the night sky. So, working together, the 31 projectors simulated nearly the entire sky.

The Munich planetarium could show how the stars would appear at any time of the night on any date from hundreds of years in the past to hundreds of years in the future. However, the planetarium was limited to views from Munich and other places that have the same northern latitude as that city. That is, the planetarium could show only stars that rose above the horizon at the latitude of Munich.

But improved versions of the Munich planetarium could simulate the sky as seen from any place on Earth and at any time up to 26,000 years into the past or future. The improved planetariums used two large star balls with the planet projectors in between.

The stars look the same from any place in the solar system—though the planets do not. Thus, the planetariums' simulations represented views of the stars as seen from any place in the solar system. The stars look the same because the solar system is much smaller than the distances to the stars. The average radius of the widest planetary orbit—the orbit of Pluto—is roughly $3 \frac{2}{3}$ billion miles (5.9 billion kilometers). The distance to the nearest star, Proxima Centauri, is about 25 trillion miles (40 trillion kilometers).

The success of the Zeiss projectors led to the establishment of thousands of planetariums in the 1900's. In the 1930's, the first Zeiss projectors were installed in the United States—at the Adler Planetarium in Chicago, the Hayden Planetarium in New York City, the Fels Planetarium at the Franklin Institute in Philadelphia, and the Griffith Observatory in Los Angeles. During the late 1900's, the Japanese firms Goto Optical Manufacturing Company and Minolta Company Limited and the U.S. company Spitz Incorporated also became leading makers of planetarium projectors.

The most advanced mechanical projectors can create images as sharp and as precise in color as the actual stars seen from a high mountain. One such device, a Zeiss Mark IX at the Hayden Planetarium in the Rose Center for Earth and Space in New York City, can project images of more than 9,000 stars. The projector has 32 star plates. Light for each star travels from a central lamp through an *optical fiber,* a hair-thin strand of glass. Because the fiber is so tiny, the image on the dome is pointlike—just like a real star in the sky. Separate projectors steered by computer-controlled motors create images of the sun, the moon, and planets.

Digital projectors. Even the best mechanical projectors can show the stars as seen from only one region of space—our solar system. The projectors have this limitation because the holes in their star plates cannot change position relative to one another.

However, a digital projector system does not use star plates, and so it does not have this limitation. Instead, a computer creates images on video screens. A lens then projects each image onto the dome. To show the stars as seen from a place other than the solar system, the computer merely changes the images on the screens. A planetarium with computerized projectors is known as a *digital planetarium* because computers use a code of numbers, or *digits,* to process information.

In the early 1980's, the Evans and Sutherland Corporation of the United States installed the first digital planetarium in the Science Museum in Richmond, Virginia. A computer created a single video image of the starry sky. A single large lens then projected this image onto the planetarium dome.

By the mid-1990's, digital planetariums produced by Evans and Sutherland and other companies brought new realism to images of planets. These advanced planetariums can create close-up views of a rotating planet.

The Gottorp Globe, built in the mid-1600's, was a hollow sphere with a bench for viewers. The bench stood still while a painting of the starry sky rotated, imitating the apparent nightly movement of the stars.

addition, they can simulate the view from a space pbe flying over a planet's surface. And they can even ow images of objects that are important in fields other tn astronomy. For instance, digital planetariums can nulate a "flight" through a tremendously magnified iage of a living cell.

In addition, digital planetariums can present shows f pure entertainment. One example of such a show is a play of animated, computer-generated art, accompaed by a musical sound track.

A digital planetarium at the Hayden Planetarium uses ven video projectors together to create a single ime. The computer is similar to machines used by *flight nulators,* devices that imitate an airplane in flight.

Even an ordinary desktop or laptop computer that is nning certain astronomy software can be thought of a digital planetarium. Computer programs available CD-ROM's can simulate sky conditions for any date d time. Many such programs contain photographs d motion pictures of astronomical objects. Such imes are also available on the Internet.

Portable planetariums. Many school systems and mmunities purchase inexpensive portable planetarins. One model has an inflatable dome that is designed hold 35 children. The projector consists of a small ht bulb surrounded by a plastic cylinder. Many cylinrs are available. For projecting the stars, there is a ack cylinder with clear spots for the stars. Other cylinrs show galaxies, constellations, and even the inside a living cell. James S. Sweitzer

lankton is the mass of tiny organisms that drifts at or ar the surface of oceans, lakes, and other bodies of ater. The word *plankton* comes from a Greek word at means *wandering.* Some planktonic organisms can vim, but they cannot swim strongly enough to avoid eing carried about by water currents.

A wide variety of organisms make up plankton. Many nnot be seen without a microscope. Scientists often vide plankton into two main types based on the organms it contains. These types are *phytoplankton* and *zoolankton.* Phytoplankton consists chiefly of simple, oneelled algae. Zooplankton includes microscopic rotozoans and such sea animals as copepods, water eas, and jellyfish.

Some organisms spend their entire life as plankton. hey are called *holoplankton.* Other organisms, called *eroplankton,* spend only part of their life as plankton. he most common meroplanktonic organisms are the ggs and *larvae* (immature forms) of animals that live on e floors of shallow oceans. These organisms drift eely as plankton until they develop into adults and sete to the bottom. Other meroplanktonic organisms inlude the eggs and larvae of larger, freely swimming annals, such as fish and squid.

Plankton plays an important part in *food webs* in bodes of water. Food webs are the feeding relationships etween organisms. Phytoplankton forms the base of ese food webs. Phytoplankton can grow using only unlight and the minerals in water in a process called *hotosynthesis.* Certain zooplankton eat phytoplankton. hese zooplankton are eaten by larger zooplankton and y fish and other water animals. Food material prouced by plankton also may sink and be consumed by ottom-dwelling organisms. David L. Garrison

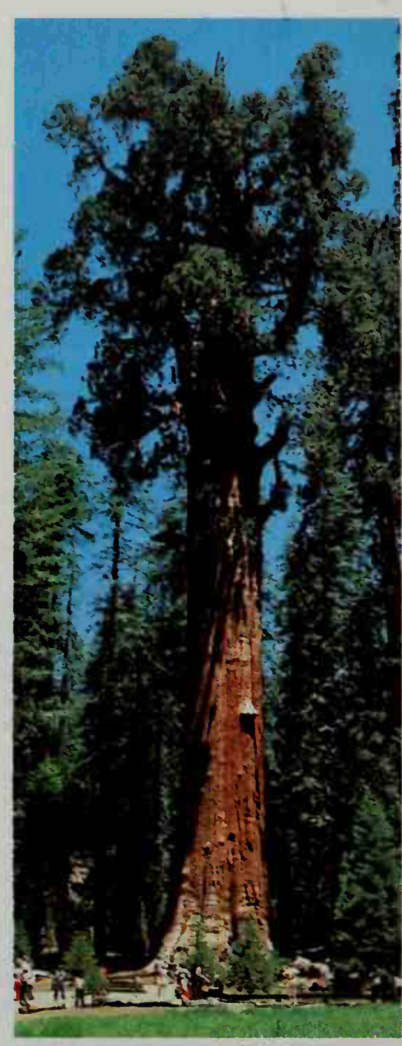
Planned Parenthood Federation of America is an organization concerned mainly with voluntary family planning and reproductive health care. The federation, often called Planned Parenthood or PPFA, seeks to ensure that people have access to birth control and to medically safe and legal abortions. Every year, millions of people receive medical care or information from PPFA clinics in about 1,000 communities throughout the United States. PPFA is a member of the International Planned Parenthood Federation and supports family planning projects in many other countries.

Services. PPFA clinics provide counseling and information on birth control and related health issues. They supply birth control devices and related medical services. PPFA clinics promote early detection of cancers of the reproductive system, offer counseling and screening services for AIDS and other sexually transmitted diseases, and provide medical care for pregnant women. PPFA clinics also offer menopause counseling and related services. Some PPFA clinics perform abortions. The organization also provides infertility treatment for men and women and counseling on adoption procedures.



Funding for PPFA comes from private contributions, government grants, patient fees, and other payments for services. The organization's headquarters are in New York City.

History. Planned Parenthood traces its origins to 1916, when Margaret Sanger, an American nurse, opened the first birth control clinic in the United States. The clinic, in New York City, was closed under a state law that forbade the discussion of birth control. In 1921, Sanger founded the Birth Control League to promote family planning. The league became the Planned Parenthood Federation of America in 1942.

Many people support work done by Planned Parenthood. Corporations, foundations, and thousands of individuals contribute money annually. However, PPFA also faces opposition. Some groups criticize it for providing birth control information and services to adolescents. Some people object to PPFA's support of abortion.

Moss plants growing on a rock

Plants vary greatly in size and form, ranging from tall, majestic trees to tiny, simple mosses. More than 260,000 species of plants grow in all parts of the world. Plants supply people with food and many other useful products. They also add beauty and pleasure to people's lives.

Plant

Plant. Plants grow in almost every part of the world. We see such plants as flowers, grass, and trees nearly every day. Plants also grow on mountaintops, in the oceans, and in many desert and polar regions.

Without plants, there could be no life on the earth. People could not live without air or food, and thus could not live without plants. The oxygen in the air we breathe comes from plants. Our food comes from plants or from animals that eat plants. We build houses and make many useful products from lumber. Much of our clothing is made from the fibers of the cotton plant.

Scientists believe there are over 260,000 *species* (kinds) of plants, but no one knows for sure. Some tiny plants that grow on the forest floor can barely be seen. Others tower over people and animals. Among the largest living things on the earth are the sequoia trees of California. Some stand over 290 feet (88 meters) high and measure over 30 feet (9 meters) wide. Plants also are the oldest living things. One bristlecone pine tree in California started growing 4,000 to 5,000 years ago.

Scientists divide all living things into five main groups called *kingdoms*. These kingdoms are (1) plants, (2) animals, (3) fungi, (4) protists, and (5) prokaryotes. Scientists classify organisms in a particular kingdom because

ıe organisms share certain basic characteristics. These haracteristics include physical structure, means of obıining food, and means of reproduction.

Plants have characteristics that set them apart from ther living things. For example, both plants and aniıals are complex organisms that are made up of many ypes of cells. But plant cells have thick walls that consist f a material called *cellulose.* Animal cells do not have ıis material. The cells of prokaryotes and some protists, ke those of plants, have cellulose walls. But prokaryotes and protists are simple organisms made up of one ell or only a few types of cells. Bacteria, including *yanobacteria* (blue-green algae), are prokaryotes. Prosts include other algae and diatoms and protozoans.

All plants develop from a tiny form of the plant called n *embryo.* Prokaryotes, protists, and fungi—such as molds and mushrooms—do not develop from embryos. Plants also obtain food in ways different from those of most other organisms. Almost all kinds of plants stay in one place for their entire lives. Most plants make their own food from air, sunlight, and water by a process called *photosynthesis.* Fungi cannot make their own food. They obtain the nutrients they need from the animals, plants, and decaying matter on which they live. Animals also cannot make their own food, but most animals can move about to find it.

This article provides general information on the plant kingdom. It tells why plants are important to people and describes the major groups of plants and where and how they live. It includes a classification table of the plant kingdom. See the *Related articles* at the end of this article for a list of articles on many kinds of plants.

The importance of plants

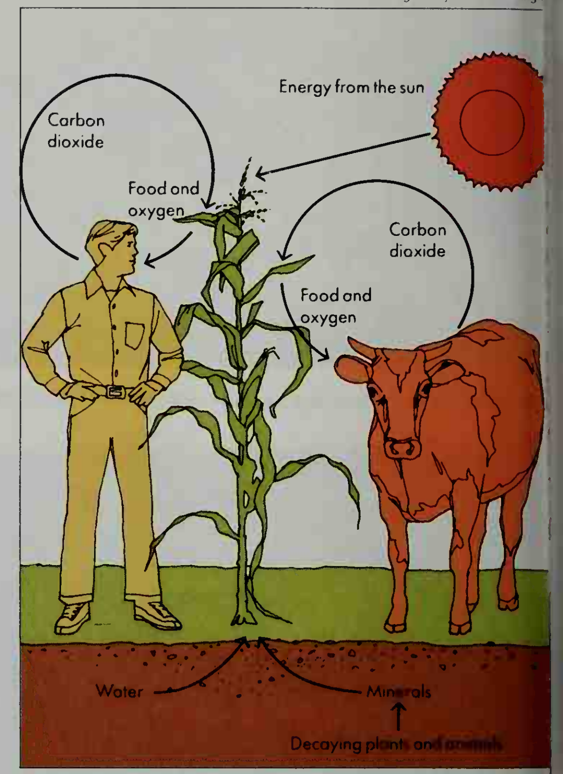
Plants supply people with food, clothing, and shelter. Many of our most useful medicines are also made from plants. In addition, plants add beauty and pleasure to our lives. Most people enjoy the smell of flowers, the sight of a field of waving grain, and the quiet within a forest.

Not all plants are helpful to people. Some species grow in fields and gardens as weeds that choke off useful plants. Tiny bits of pollen from certain plants cause such health problems as asthma and hay fever. Some plants are poisonous if eaten. Others, such as poison ivy and poison oak, irritate the skin.

Food. Plants are probably most important to people as food. Sometimes we eat plants themselves, as when we eat apples, peas, or potatoes. But even when we eat meat or drink milk, we are using foods that come from an animal that eats plants.

People get food from many kinds of plants—or parts of plants. The seeds of such plants as corn, rice, and wheat are the chief source of food in most parts of the world. We eat bread and many other products made from these grains, and almost all our meat comes from animals that eat them. When we eat beets, carrots, or sweet potatoes, we are eating the roots of plants. We eat the leaves of cabbage, lettuce, and spinach plants; the stems of asparagus and celery plants; and the flower buds of broccoli and cauliflower plants. The fruits of many plants also provide us with food. They include apples, bananas, berries, and oranges, as well as some nuts and vegetables. Coffee, tea, and many soft drinks get their flavor from plants.

Raw materials. Plants supply people with many important raw materials. Trees give us lumber for building homes and making furniture and other goods. Wood chips are used in manufacturing paper and paper products. Other products made from trees include cork, natural rubber, maple syrup, and turpentine. Most of the world's people wear clothing made from cotton. Threads of cotton are also woven into carpets and other goods. Rope and twine are made from hemp, jute, and sisal plants.



Plants also provide an important source of fuel. In many parts of the world, people burn wood to heat their homes or to cook their food. Other important sources of fuel—coal, oil, and natural gas—also come from plants. Coal began to form millions of years ago, when great forests and swamps covered much of the earth. As the trees in these forests died, they fell into the swamps, which were then covered by mud and sand. The increasing pressure of this mass of materials helped cause the dead plants to turn into coal. Petroleum and natural gas were formed in ancient oceans by the pressure of mud, sand, and water on decaying masses of plants and animals.

Medicines. Many useful drugs come from plants. Some of these plants have been used as medicines for hundreds of years. More than 400 years ago, for example, some Indian tribes of South America used the bark of the cinchona tree to reduce fever. The bark is still used to make *quinine,* a drug used to treat malaria and other diseases. Another drug, called *digitalis,* is used in treating heart disease. It is made from the dried leaves of the purple foxglove plant. The roots of the Mexican yam are used in producing *cortisone,* a drug useful in treating arthritis and a number of other diseases.

Plants and the cycle of nature

Plants play an important part in the cycle of nature. They grow by taking energy from the sun, carbon dioxide from the air, and water and minerals from the ground. During the cycle, plants supply us with food and give off the oxygen that we breathe.

WORLD BOOK diagram by David Cunningh

Plants and the cycle of nature. All living things—plants, animals, fungi, protists, and prokaryotes—are linked by the *cycle of nature.* This natural process gives people oxygen to breathe, food to eat, and heat to keep them warm. The sun supplies the energy that runs the cycle.

Plants have a complex relationship with people and animals in the cycle of nature. Plants use sunlight to make their own food, and they give off oxygen during the process. People and animals eat the plants and breathe in the oxygen. In turn, people and animals breathe out carbon dioxide. Plants combine the carbon dioxide with energy from sunlight and water and minerals from the soil to make more food. After plants and animals die, they begin to decay. The rotting process returns minerals to the soil, where plants can again use them.

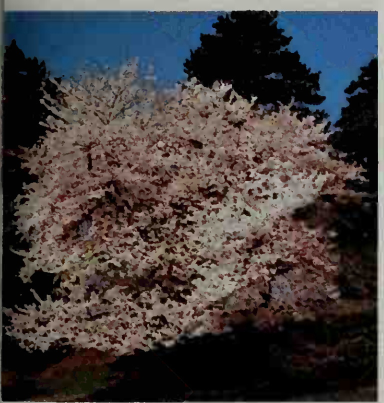
Plants also play an important part in *conservation,* the protection of soil, water, wildlife, and other natural resources. Plants help keep the soil from being blown away by the wind or washed away by the water. They slow down the flow of water by storing it in their roots, stems, and leaves. Plants also give wild animals food to eat and a safe place to live. For more information on the importance of plants in nature, see the *World Book* articles on **Balance of nature, Conservation,** and **Ecology.**

Each of the more than 260,000 species of plants differs ɔm every other species in one or more ways. How- er, plants also have many features in common. Based ı these similarities, scientists are able to classify dis- ıct plants into groups. The study of plants is called *ɔtany,* and scientists who study plants are known as *ɔtanists.*

This section describes the chief kinds of plants found the plant kingdom. It is divided into five basic groups: seed plants, (2) ferns, (3) lycopsids, (4) horsetails, and bryophytes. A table showing a more detailed system plant classification that is used by many botanists ap- ɜars at the end of the article. See also **Classification, :ientific.**

Seed plants consist of a wide variety of plants that ɜar seeds to reproduce. Most botanists divide the seed ants into two main groups of plants—angiosperms *and* /mnosperms.

Angiosperms are flowering plants. They make up the ıst majority of the more than 260,000 kinds of plants. ıey produce seeds that are enclosed in a protective ɜed case. The word *angiosperm* comes from two reek words meaning *enclosed* and *seed.* All plants that roduce flowers and fruits are angiosperms. They in- ude most of our common plants, such as brightly colored garden plants, many kinds of wildflowers, and most trees, shrubs, and herbs. Most of the plants that produce the fruits, grains, and vegetables that people eat also are angiosperms. See **Angiosperm.**



The sizes of angiosperms vary greatly. The smallest flowering plant, the duckweed, is only about $\frac{1}{50}$ inch (0.5 millimeter) long. It floats on the surface of ponds. The largest angiosperms are eucalyptus trees. They grow more than 300 feet (91 meters) tall.

Some botanists divide the angiosperms into two smaller groups. Plants in one group, called *monocotyledons* or *monocots,* grow from seeds that contain one seed leaf called a *cotyledon* (see **Cotyledon**). Plants in the other group, called *dicotyledons* or *dicots,* have two cotyledons in their seeds.

Gymnosperms include a wide variety of trees and shrubs that produce naked or uncovered seeds. Most gymnosperms bear their seeds in cones. The word *gymnosperm* comes from two Greek words meaning *naked* and *seed.* Gymnosperms do not produce flowers. This group is made up of such plants as conifers, cycads, ginkgoes, and gnetophytes. See **Gymnosperm.**

Conifers are the best known of the gymnosperms. They include such trees as cedars, cypresses, firs, pines, redwoods, and spruces. Most conifers have needlelike

ngiosperms Any plant that produces flowers and fruits is considered an angiosperm. The vast majority of all the many kinds of plants belong to this group.

or scalelike leaves. Their seeds grow on the upper side of the scales that make up their cones. The cones of some conifers, such as junipers, look like berries. Most conifers are *evergreens*—that is, they shed old leaves and grow new leaves continuously and so stay green throughout the year. Wood from conifers is widely used in construction and papermaking. Conifers also provide animals with food and shelter. See **Conifer**.

Cycads and ginkgoes have lived on the earth for millions of years. Large numbers of these plants once grew over wide regions of land. Most cycads look much like palm trees. They have a branchless trunk topped by a crown of long leaves. But unlike palm trees, they bear their seeds in large cones. Only one kind of ginkgo survives today. It is an ornamental tree with flat, fan-shaped leaves. It bears seeds at the ends of short stalks along its branches. See **Cycad; Ginkgo**.

Gnetophytes are the gymnosperms most closely related to angiosperms. They have many features that resemble those of flowering plants. For example, *Gnetum* has broad, oval-shaped leaves and special water-transport tubes, much like those of angiosperms. The cones of all gnetophytes are flowerlike in many details.

Ferns grow chiefly in moist, wooded regions. They vary widely in size and form. Some aquatic ferns have leaves only about 1 inch (2.5 centimeters) long. But in th tropics, tree ferns may grow more than 65 feet (20 meters) high.

Fern leaves, called *fronds,* usually are made up of many tiny leaflets and may be quite large. On most typ of ferns, the fronds are the only parts that grow above the ground. They grow from underground stems that may run horizontally under the surface of the ground. When the fronds first appear, they are tightly coiled. Th fronds unwind as they grow.

During prehistoric times, great numbers of large ferns covered the earth. These ferns, along with giant club mosses and horsetails, accounted for much of the plant life that later formed coal. See **Fern**.

Lycopsids include club mosses, quillworts, and selaginellas. These plants have leaves with a single, centr vein. Lycopsids were among the first plants to grow on land.

Club mosses have tiny needlelike or scalelike leaves that usually grow in a spiral pattern. They are not true mosses. Club mosses are found from tropical to tempe ate regions. They often form a "carpet" on the forest floor. See **Club moss**.

Quillworts are found chiefly in moist soils around lakes and streams. They have short stems and long,

Gymnosperms Most of the trees and shrubs that make up this group bear their seeds in cones and have needlelike or scalelike leaves. The yew and ginkgo do not have seed cones.

Hornwort

grasslike leaves. The leaves usually grow to about 14 inches (36 centimeters) long. Ancient plants related to quillworts were large trees that grew up to 120 feet (37 meters) tall. These plants lived about 290 million years ago.

There are about 700 kinds of selaginellas. These plants are usually found in tropical and subtropical regions. They often grow in damp places on the forest floor. Selaginellas have small, thin leaves. Their stems may either grow upright or along the ground. These plants first appeared on earth over 300 million years ago.

Horsetails are a group of small plants that have hollow, jointed stems. Horsetails grow about 2 to 3 feet (60 to 90 centimeters) tall. The plants have green stems and tiny, black leaves. The stems capture the sunlight used by the plant to make food in photosynthesis. In some horsetails, the branches grow in *whorls* (circles) around the main stem of the plant, and the plant resembles a horse's tail. Tiny amounts of minerals are concentrated in the stems of horsetails, including gold and silica. Silica makes the stems very coarse, like sandpaper. Som kinds of horsetails are called *scouring rush* because people once used these plants to scour their pots and pans. See **Horsetail.**

Bryophytes are a group made up of liverworts, mosses, and hornworts. These plants live in almost all parts of the world, from the Arctic to tropical forests. They grow in such moist, shady places as forests and ravines. Bryophytes are the only types of plants that lac *vascular tissue*—that is, tissue that carries water and food throughout the plant.

Most liverworts, mosses, and hornworts measure le than 8 inches (20 centimeters) tall. None of these plants have true roots. Instead, they have hairy rootlike growths called *rhizoids* that anchor the plants to the so and absorb water and minerals.

Peat moss, a substance made up of thick growths of *Sphagnum* and other mosses, is often used in gardening. Gardeners mix peat moss into the soil to keep the soil loose and to help it hold moisture. See **Hornwort; Liverwort; Moss.**

Where plants live

Most species of plants live in places that have warm temperatures at least part of the year, plentiful rainfall, and rich soil. But plants can live under extreme conditions. Mosses have been found in Antarctic areas where the temperature seldom rises above 32 °F (0 °C). Many desert plants grow in areas where the temperature may rise well above 100 °F (38 °C).

Not all kinds of plants grow in all parts of the world. For example, cattails live only in such damp places as swamps and marshes. Cactuses, on the other hand, are found chiefly in deserts. Through long periods of time, many small changes have taken place in various kinds of plants. These changes have enabled the plants to survive in a particular environment. For a discussion of some of these changes, see the section of this article *How plants change.*

Many elements make up a plant's environment. One of the most important is the weather—sunlight, temperature, and *precipitation* (rain, melted snow, and other moisture). The environment of a plant also includes the soil and the other plants and the animals that live in the same area. All these elements form what scientists call a *natural community.*

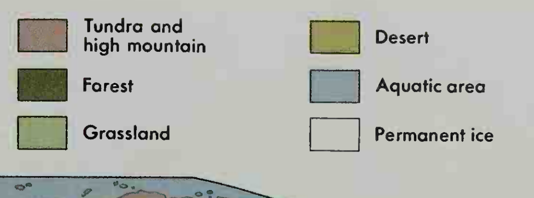
No two natural communities are exactly alike, but many resemble one another more than they differ. Botanists divide the world into *biomes*—natural communities of plants, animals, and other organisms. Important land biomes include (1) the tundra, (2) forests, (3) chaparrals, (4) grasslands, (5) savannas, and (6) deserts. Forests are often subdivided into smaller biomes, such as temperate deciduous forests and tropical rain forests. In addition, many plants live in *aquatic* (water) regions that are not grouped as a specific biome. See **Biome.**

Human beings have greatly affected the natural communities. In North America, for example, great forests once extended from the Atlantic Ocean to the Mississippi River. Most of the trees were cleared by advancing settlers, and the forests have been replaced by cities and farms. In other parts of the world, irrigation and the use of fertilizers have enabled plants to be grown on once-barren land.

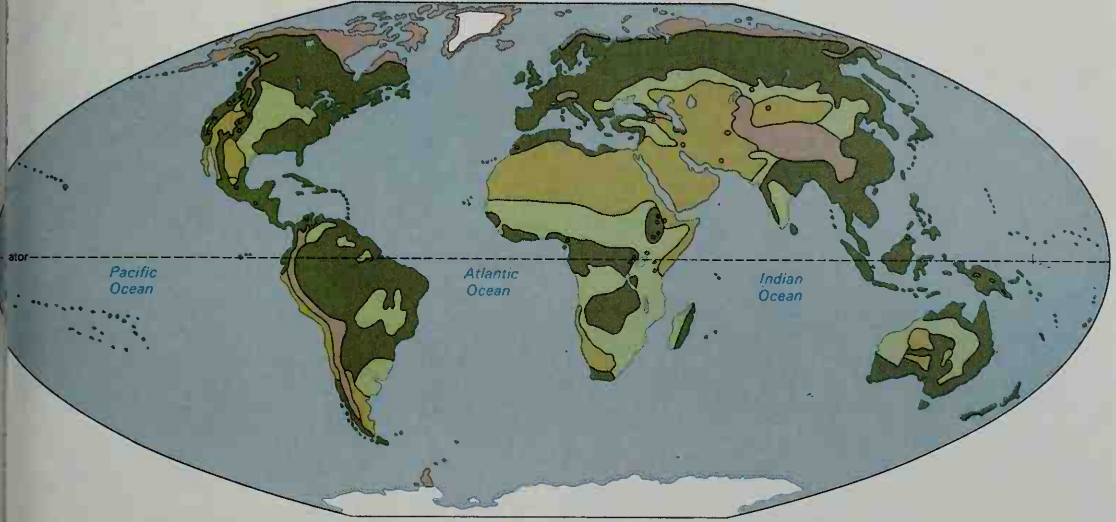
This section describes the natural plant life in the im portant land biomes and in aquatic regions. For inform tion on where animals live, see the **Animal** article. For discussion of the relationship between living things an their environment, see **Ecology.**

The tundra is a cold, treeless area that surrounds th Arctic Ocean, near the North Pole. It extends across the uppermost parts of North America, Europe, and Asia. The land in these regions is frozen most of the year, an the annual precipitation measures only from 6 to 10 inches (15 to 25 centimeters). The upper slopes of the world's highest mountains—the Alps, the Andes, the Himalaya, and the Rockies—have conditions similar to those in the tundra.

Summers in the tundra last only about 60 days, and summer temperatures average only about 45 °F (7 °C). The top 1 foot (30 centimeters) or so of the land thaws during the summer, leaving many marshes, ponds, and swamps. Such plants as mosses, shrubs, and wildflowers grow in the tundra. These plants grow in low clump and so are protected from the wind and cold. A thick growth of *lichens* (organisms made up of algae and fungi) covers much of the land. See **Tundra.**



Forests cover almost a third of the earth's land area. They consist chiefly of trees, but many other kinds of plants also grow in forests. Some botanists divide the many types of forests into three major groups: (1) coniferous forests, (2) temperate deciduous forests, and (3) tropical rain forests.



Coniferous forests are made up mainly of trees that are *coniferous* (cone-bearing) and evergreen. Most eco ogists distinguish between *boreal forests,* also called *taiga,* and *temperate coniferous forests.*

Boreal forests grow in regions that have a short summer and a long, cold winter. The growing season in these regions may last less than three months. Boreal forests are found in the northernmost parts of North

jor plant regions of the world

its live everywhere except in regions that have permanent
But not all plants grow in all regions of the world. This map
ws the five major regions in which certain kinds of plants
w best. For example, cacti grow chiefly in deserts, and cat-
in *aquatic* (watery) regions.

erica, Europe, and Asia. They also grow in the high
untains of these continents. Trees found in boreal
ests include such evergreen conifers as balsam firs,
ck spruces, jack pines, and white spruces. The
nty, triangular shape of these trees helps them shed
vy snow.

ew plants grow on the floor of boreal forests. Thick
ers of old needles build up beneath the trees. These
edles contain acids that are slowly released as the
edles decay. Water carries the acids into the soil. The
dic water dissolves many minerals and carries them
the deeper layers of the soil. As a result, the topsoil
nd in boreal forests is often very sandy and unable to
port many types of small plants.

Temperate coniferous forests grow in western North
erica in areas that have mild, wet winters and dry
nmers. The redwood forests of northern California
l the temperate rain forests found on the Olympic
insula of Washington are both examples of temper-
coniferous forests. Major trees of the temperate co-
erous forest include redwoods and giant sequoias in
south and Douglas-firs, hemlocks, cedars, and pines
nore northern areas.

emperate deciduous forests cover large areas of
rth America, central Europe, east Asia, and Australia.
he United States, temperate deciduous forests grow
stly east of the Mississippi River and extend north-
rd into the Northern States and southern Canada,
ere they become mixed with coniferous forests. Most
hese areas have cold winters and warm, wet sum-
rs.

Most of the trees in temperate deciduous forests are
ed *broadleaf trees* because they have broad, flat
ves. They also are *deciduous*—that is, they lose their
ves every fall and grow new ones in the spring. Trees
that grow in temperate deciduous forests include bass-
woods, beeches, birches, hickories, maples, oaks, pop-
lars, tulips, and walnuts. A thick growth of wild flowers,
seedlings, and shrubs covers the floor of most of these
forests.

Tropical rain forests grow in regions that have warm, wet weather the year around. These regions include Central America and the northern parts of South America, central and western Africa, Southeast Asia, and the Pacific Islands.

Most trees in tropical rain forests are broadleaf trees. Because of the warm, wet weather, they never completely lose their leaves. These trees lose a few leaves at a time throughout the year. Many kinds of trees grow in tropical rain forests, including mahoganies and teaks. The trees grow so close together that little sunlight can reach the ground. As a result, only ferns and other plants that require little sunlight can grow on the forest floor. Many plants, including lichens, orchids, and vines, grow high on the trees.

The heavy rainfall that occurs in tropical rain forests dissolves much of the nutrients and organic materials out of the soil. As a result, the soils found in tropical rain forests contain a very small amount of nutrients and organic matter. However, the soil is able to support the lush growth found in these forests because fresh nutrients from the decay of fallen leaves are continually being released into the soil.

Chaparrals consist of thick growths of shrubs and small trees. Cork and scrub oaks, manzanitas, and many unusual herbs are often found on chaparrals. Chaparrals occur in areas that have hot, dry summers and cool, wet winters. Such areas are found in the western part of North America, the southern regions of Europe near the Mediterranean Sea, the Middle East, northern Africa,

Plants of the coniferous forest

Towering trees, such as hemlocks, cedars, and Douglas-firs, dominate the temperate coniferous forest on the Olympic Peninsula of Washington. Many small plants grow on the forest floor.

1. Western redcedar
2. Western sword fern
3. Sitka spruce
4. Horsetail
5. Douglas-fir
6. Wood sorrel
7. Piper bellflower
8. Western hemlock

d the southern parts of South America, Africa, and stralia.

During the dry summer season, fires are common on aparrals. But these fires actually help to maintain the nt life. Many of the plants that grow on chaparrals are her resistant to fire or are able to grow back quickly er they burn. The fires clear the dense vegetation ay and expose bare ground to allow for new growth. e heat of the fires also stimulates development in the eds of some plants. In addition, many types of short-ed, small flowers appear only after a fire has taken ce. See **Chaparral**.

Grasslands are open areas where grasses are the st plentiful plants. In the United States and Canada, st of the natural grasslands are used to grow crops. ere, farmers and ranchers grow such grains as barley, ts, and wheat where bluestem, buffalo, and grama sses once covered the land.

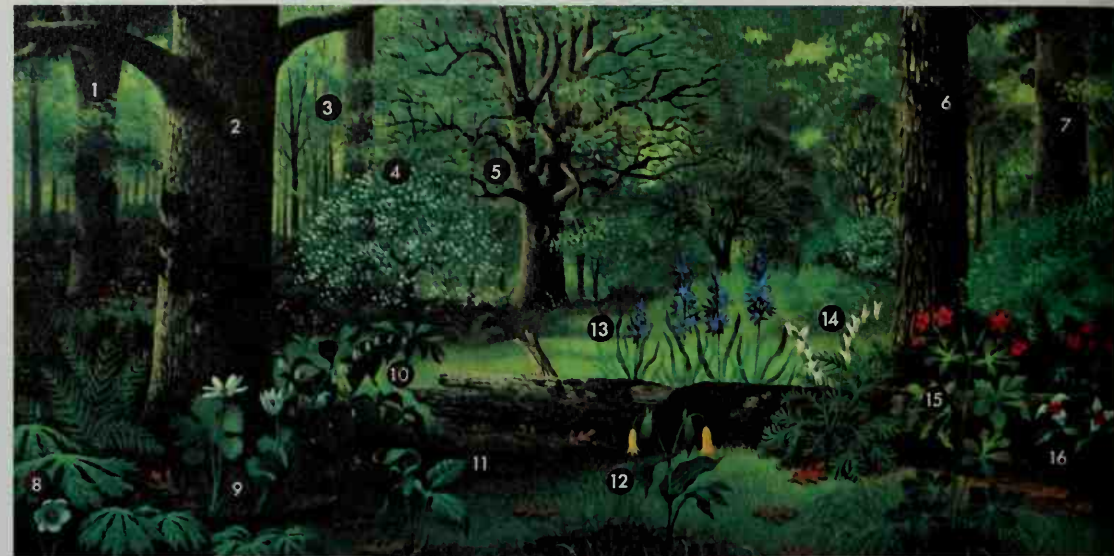
Botanists divide grasslands into *steppes* and *prairies.* ly short grasses grow on steppes. These dry areas in-de the Great Plains of the United States and Canada, *veld* of South Africa, and the plains of Kazakhstan d southern Russia. Taller grasses grow on the prairies the American Midwest, eastern Argentina, and parts Europe and Asia. Rolling hills, clumps of trees, and ers and streams break up these areas. Most of the soil ich and rainfall is plentiful. As a result, prairie land is ed almost entirely to raise food crops and livestock. e **Grassland**.

Savannas are grasslands with widely spaced trees. me savannas are found in regions that receive little n. Others are found in tropical regions, such as the mos of Venezuela, the Campos of southern Brazil, d the Sudan of Africa. Most of these areas have dry nters and wet summers. Grasses grow tall and stiff der such conditions. Acacia, baobab, and palm trees ow on many savannas. A wide variety of animals, such antelope, giraffes, lions, and zebras, roam the savan-s of Africa. See **Savanna**.

Deserts cover about a fifth of the earth's land. A huge sert region extends across northern Africa and into ntral Asia. This region includes three of the world's eat deserts—the Arabian, the Gobi, and the Sahara. her major desert regions of the world include the cama Desert along the western coast of South Amer-, the Kalahari Desert in southern Africa, the Western teau of Australia, and the southwest corner of North erica.

Some deserts have almost no plant life at all. Parts of Gobi and the Sahara, for example, consist chiefly of fting sand dunes. All deserts receive little rain and e either rocky or sandy soil. The temperature in most serts rises above 100 °F (38 °C) for at least part of the r. Some deserts also have cold periods. But in spite hese harsh conditions, many plants live in desert re-ns. These plants—sometimes called *xerophytes*—in-de acacias, cactuses, creosote bushes, Joshua trees, ebrush, and yuccas. wildflowers are also found in desert. See **Flower** (Flowers of the desert [with tures]).

Desert plants do not grow close together. By being ead out, each plant can get water and minerals from rge area. The roots of most desert plants extend over ge areas of land, and they capture as much rain



WORLD BOOK illustration by Lowell Hess

Plants of the tropical rain forest

Trees grow close together in this African rain forest, and vines climb high on the trees. Most of these plants are listed by their scientific names, though all have local common names.

1. *Lophira procera*
2. *Scottellia kamerunensis*
3. *Casearia bridelioides*
4. *Pausinystalia*
5. *Strombosia pustulata*
6. *Picralima umbellata*
7. *Diospyros insculpta*
8. Lianas
9. Strangler fig
10. *Ako ombe*

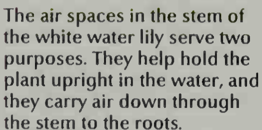
Plants of a freshwater pond

Many species of plants grow in and around ponds and other bodies of fresh water. Some of these plants live completely underwater, but others grow partly in and partly out of the water.

1. Reed grass	5. Blue flag	9. Cattail	13. Water milfoil
2. Black willow	6. Swamp-loosestrife	10. Pickerelweed	14. Bladderwort
3. Silver maple	7. Sphagnum moss	11. White water lily	15. Wild celery
4. Purple loosestrife	8. Sedge	12. Yellow water lily	



Special features of freshwater plants

Plants that live in ponds have special features that enable them to survive. The features of two kinds of these plants, the white water lily and a water milfoil, are shown below.

WORLD BOOK illustrations by Margaret Ann Moran

The air spaces in the stem of the white water lily serve two purposes. They help hold the plant upright in the water, and they carry air down through the stem to the roots.

The long, underwater leaves of the water milfoil are especially suited to absorb carbon dioxide from the water. The leaves that grow above water resemble those of land plants.

water as possible. Cactuses and other *succulent* (juicy plants store water in their thick leaves and stems. See **Cactus; Desert.**

Aquatic regions are bodies of fresh or salt water. Freshwater areas include lakes, rivers, swamps, and marshes. Coastal marshes and oceans are saltwater re gions. Most aquatic plants, which are also called *hydr phytes,* live in places that receive sunlight. These plant grow near the water surface, in shallow water, or alon the shore.

Some kinds of aquatic plants, including eelgrass, liv completely under the surface of the water. Other species of aquatic plants, such as duckweed, the smallest known flowering plant, float freely on the surface. Still others, such as the water marigold, grow only partly u derwater. Many aquatic plants have air spaces in their stems and leaves. The air spaces help them stand erec or stay afloat.

Aquatic regions have unique conditions that make i difficult for many types of plants to grow there. For example, swamps and marshes, as well as flood plains along many streams and rivers, become flooded leavi the plants that live in these areas completely covered l water. As a result, only a few species of plants are able to survive in aquatic regions. Common freshwater pla include duckweeds, pondweeds, water lilies, sedges, and cattails. Such trees as baldcypresses, blackgums, and willows also grow in fresh water. Saltwater plants include eelgrass, cordgrass, and many types of sedge See **Water plant.**

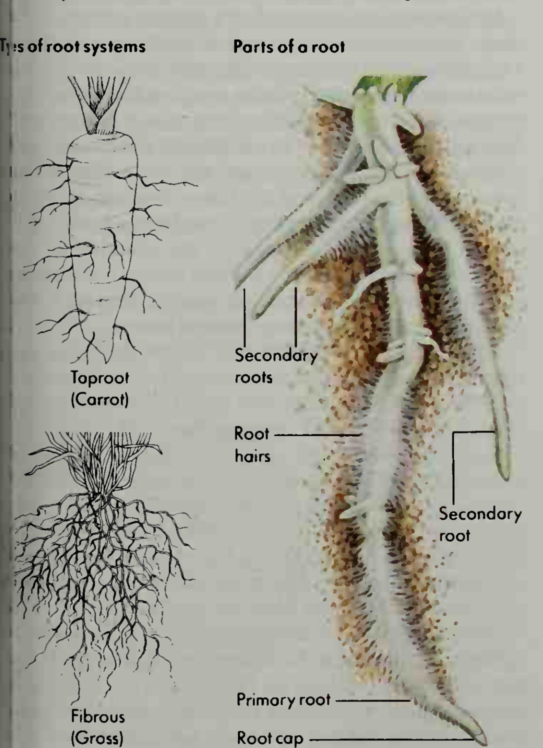
ıll plants—like all living things—are made up of cells. Ir lants, there are many kinds of cells that have special jcs, and together these cells form the various parts of th plant. A giant redwood tree, for example, has many b ons of cells. See **Cell.**

group of cells that are organized to perform a parti lar function is called a *tissue.* Plants are made up of m iy types of complex tissues. All plants, except b ophytes—that is, mosses, liverworts, and h nworts—have conducting tissue that carries water, m erals, and other nutrients throughout the plant body. T s tissue is called *vascular tissue.* It is made up of two s cialized tissues called *xylem* and *phloem.* The xylem ti ue consists of cells that carry water and minerals fr n the roots to the leaves. The phloem tissue is made u of cells that carry food made by photosynthesis in th leaves to the other parts of the plant. Plants that have th se special tissues are called *vascular plants.* Bryop tes are called *nonvascular plants* because they lack xy m and phloem.

ı plant is made up of several important parts. Flowerir plants, the most common type of plants, have four m n parts: (1) roots, (2) stems, (3) leaves, and (4) flowers. T roots, stems, and leaves are called the *vegetative* p ts of a plant. The flowers, fruits, and seeds are known a he *reproductive* parts.

toots. Most roots grow underground. As the roots o young plant spread, they absorb the water and mine s that the plant needs to grow. The roots also anchor the plant in the soil. In addition, the roots of some plants store food for the rest of the plant to use. Plants with storage-type roots include beets, carrots, radishes, and sweet potatoes.

There are two main kinds of root systems—*fibrous* and *taproot.* Grass is an example of a plant with a fibrous root system. It has many slender roots of about the same size that spread out in all directions. A plant with a taproot system has one root that is larger than the rest. Carrots and radishes have taproots. Taproots grow straight down, some as deep as 15 feet (4.6 meters).

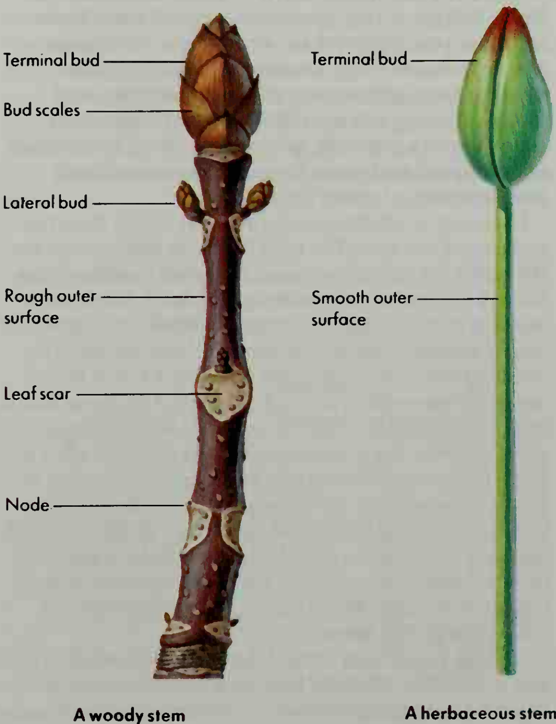


The root is one of the first parts of a plant that starts to grow. A *primary root* develops from a plant's seed and quickly produces branches called *secondary roots.* At the tip of each root is a *root cap* that protects the delicate tip as it pushes through the soil. Threadlike *root hairs* grow farther back on the root of the plant. Few of these structures are over $\frac{1}{2}$ inch (13 millimeters) long. But there are so many of them that they greatly increase the plant's ability to absorb water and minerals from the soil.

The roots of some aquatic plants float freely in the water. Other plants, such as orchids and some vines, have roots that attach themselves to tree branches.

The roots of almost all land plants have a special relationship with fungi. In this relationship, known as *mycorrhiza,* fungi cover or penetrate the growing tips of a plant's roots. Water and nutrients enter the roots through the fungi. Fungi extend the plant's root system

R ots



M st roots anchor a plant and absorb water and minerals. Plants h e either a fibrous root system or a taproot system, *below left.* T main parts of a root are shown below at the right.

Stems

Most stems support the plant's flowers and leaves. Stems are *woody* or *herbaceous.* A woody stem, *left,* has a rough, brown surface. A herbaceous stem, *right,* has a smooth, green surface.

and improve the plant's ability to absorb water and minerals. Many botanists believe the first land plants developed millions of years ago from algae that lived in water. They think mycorrhizal relationships may have helped these plants to grow on land. See **Root.**

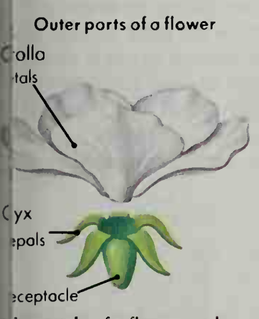
Stems of plants differ greatly among various species. They make up the largest parts of some kinds of plants. For example, the trunk, branches, and twigs of trees are all stems. Other plants, such as cabbage and lettuce, have such short stems and large leaves that they appear to have no stems at all. The stems of still other plants, including potatoes, grow partly underground.

Most stems grow upright and support the leaves and reproductive organs of plants. The stems hold these parts up in the air where they can receive sunlight. Some stems grow along the ground or underground. Stems that grow aboveground are called *aerial* stems, and those underground are known as *subterranean.* Aerial stems are either *woody* or *herbaceous* (nonwoody). Plants with woody stems include trees and shrubs. These plants are rigid because they contain large amounts of woody xylem tissue. Most herbaceous stems are soft and green because they contain only small amounts of xylem tissue.

In almost all plants, a stem grows in length from the end, called the *apex.* The cells that form this growth area are called the *apical meristem.* An apical meristem produces a column of new cells behind itself. These cells develop into the specialized tissues of the stem and leaves. A resting apical meristem and the cluster of developing leaves that surround it is called a *bud.* Buds may grow on various parts of the stem. A *terminal bud* is found at the end of a branch. A *lateral bud* develops at a point where a leaf joins the stem. This point is called a *node.* Buds may develop into new branches, leaves, or flowers. Some buds are covered with tiny overlapping leaves called *bud scales.* The bud scales protect the soft, growing tissue of the apical meristem. During the winter, the buds of many plants are *dormant* (inactive) and can be seen easily. In the spring, these buds resume their growth. See Stem.

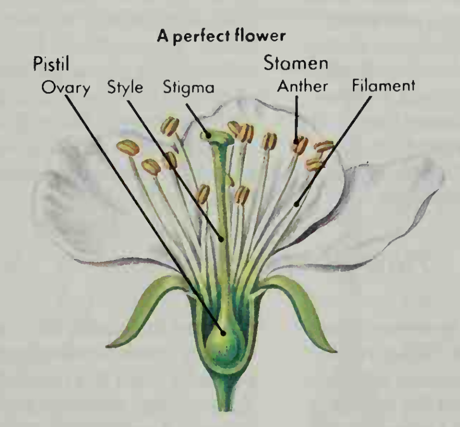
Leaves make most of the food that plants need to live and grow. They produce food by a process called *photosynthesis.* In photosynthesis, chlorophyll in the leaves absorbs light energy from the sun. This energy is usec to combine water and minerals from the soil with carbon dioxide from the air. The food formed by this process is used for growth and repair, or it is stored i special areas in the stems or roots. See **Photosynthesi**

Leaves differ greatly in size and shape. Some plants have leaves less than 1 inch (2.5 centimeters) long and wide. The largest leaves, those of the raffia palm, grov up to 65 feet (20 meters) long and 8 feet (2.4 meters) wide. Most plants have broad, flat leaves. The edges, *margins,* of these leaves may be smooth, toothed, or wavy. Grass and certain other plants have long, slende leaves. A few kinds of leaves, including the needles of pine trees and the spines of cactuses, are rounded an have sharp ends.

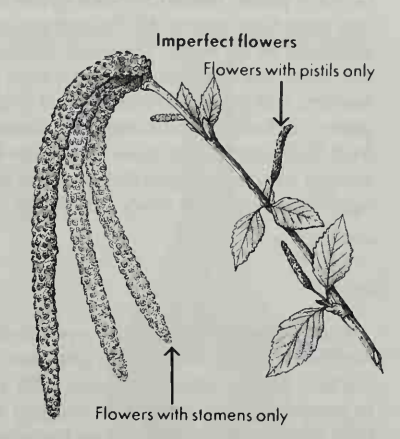


Most leaves are arranged in a definite pattern on a plant. The leaves of many kinds of plants grow in an *alternate* pattern. In this pattern, only one leaf forms a each node. On plants with the simplest kind of alterna pattern, a leaf appears first on one side of the stem an then on the other side. On plants with a more comple alternate pattern, the nodes are spaced in a *spiral* pattern around the stem and the leaves seem to encircle the stem from bottom to top. If two leaves grow from opposite sides of the same node, the plant has an *opp site* arrangement of leaves. If three or more leaves gro equally spaced around a single node on the stem, the plant has a *whorled* arrangement of leaves.

A leaf begins as a small bump next to the apical me stem of a stem. Most leaves develop two main parts— the *blade* and the *petiole.* The leaves of some plants a have a third part called *stipules.* The blade is the flat p of the leaf. Some leaves, called *simple* leaves, have on one blade. Leaves with two or more blades are called *compound* leaves. The petiole is the thin leafstalk that grows between the base of the blade and the stem. It carries water and food to and from the blade. Stipules are leaflike structures that grow where the petiole joi the stem. Most stipules look like tiny leaves.



A network of veins distributes water to the food-pro ducing areas of a leaf. The veins also help support the leaf and hold its surface up to the sun. The upper and lower surfaces of a leaf are called the *epidermis* (skin) The epidermis has tiny openings called *stomata.* Carb



F wers Flowers contain the reproductive parts of flowering plants. If a plant's reproductive organs—its *stamens* and *pistils*—are in the same flower, the flower is called *perfect.* If a flower has only stamens or only pistils, it is called *imperfect.* The outer parts of a flower are shown below at the left.

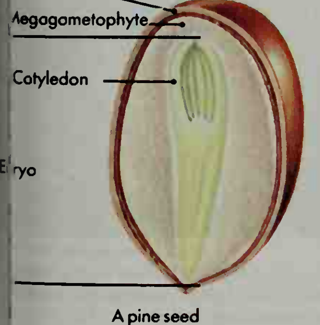
WORLD BOOK diagram by James Teason and Marion Pahl

A he petals of a flower make u he corolla. The sepals fc n the calyx. The base is c ed the receptacle.

d xide, oxygen, water vapor, and other gases pass into tl leaves and out of the leaves through the stomata. S : Leaf.

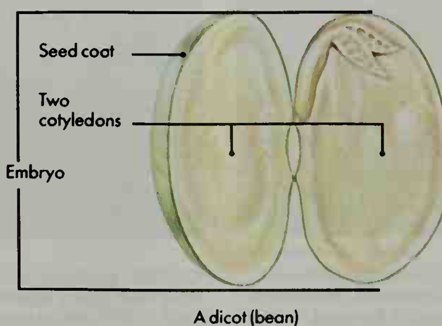
lowers contain the reproductive parts of flowering p nts. Flowers develop from buds along the stem of a p nt. Some kinds of plants produce only one flower, b others grow many large clusters of flowers. Still oth- e such as dandelions and daisies, have many tiny fl vers that form a single, flowerlike head.

Aost flowers have four main parts: (1) the *calyx,* (2) the c *olla,* (3) the *stamens,* and (4) the *pistils.* The flower p ts are attached to a place on the stem called the *re- c tacle.*



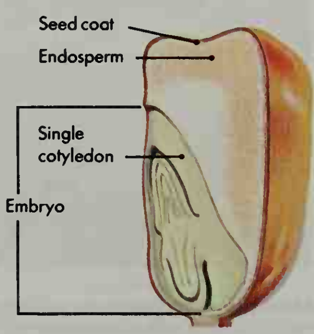
he calyx consists of small, usually green leaflike s ctures called *sepals.* The sepals protect the bud of a y ng flower. Inside the calyx are the petals. All the pet- a of a flower make up the *corolla.* The petals are the l jest, most colorful part of most flowers. The flower's r roductive organs—the stamens and the pistils—are a ched to the receptacle inside the sepals and the pet- a In many flowers, the stamens and petals are *fused* (j ned together).

stamen is a male reproductive organ, and a pistil is a female reproductive organ. Each stamen has an enlarged part called an *anther* that grows on the end of a long, narrow stalk called the *filament.* Pollen grains, which develop *sperm* (male sex cells), are produced in the anther. The pistils of most flowers have three main parts: (1) a flattened structure called the *stigma* at the top, (2) a slender tube called the *style* in the middle, and (3) a round base called the *ovary.* The ovary contains one or more structures called *ovules.* Egg cells form within the ovules. The ovules become *seeds* when sperm cells fertilize the egg cells. The next section of this article, *How plants reproduce,* tells how the sperm cells unite with the egg cells to begin the formation of seeds and fruit.



Seeds vary greatly in size and shape. Some seeds, such as those of the tobacco plant, are so small that more than 2,500 may grow in a pod less than $\frac{3}{4}$ inch (19 millimeters) long. On the other hand, the seeds of one kind of coconut tree may weigh more than 20 pounds (9 kilograms). The size of a seed has nothing to do with the size of the plant. For example, huge redwood trees grow from seeds that measure only $\frac{1}{16}$ inch (1.6 millimeters) long.

S ds All seeds are either *naked* or *enclosed.* A pine seed, *below left,* is a naked seed. It forms on a pinecone scale. There are two types of enclosed seeds—*monocots* and *dicots.* These seeds develop inside an ovary. A dicot, *center,* has two cotyledons. A monocot, *below right,* has only one.



WORLD BOOK diagram by James Teason

A pine seed

A dicot (bean)

A monocot (corn)

There are two main types of seeds—*naked* and *enclosed.* Cone-bearing plants and all other nonflowering seed plants have naked, or uncovered, seeds. The seeds of these plants develop on the upper side of the scales that form their cones. All flowering plants have seeds enclosed by an ovary. The ovary develops into a *fruit* as the seeds mature. The ovaries of such plants as apples, berries, and grapes develop into a fleshy fruit. In other plants, including beans and peas, the ovaries form a dry fruit. Still other plants have *aggregate* fruits. Each tiny section of an aggregate fruit, such as a raspberry, develops from a separate ovary and has its own seed.

Seeds consist of three main parts: (1) the *seed coat,* (2) the *embryo,* and (3) the *food storage tissue.* The seed coat, or outer skin, protects the embryo, which contains all the parts needed to form a new plant. The embryo also contains one or more cotyledons, or embryo leaves, which absorb food from the food storage tissue. In flowering plants, the food storage tissue is called *endosperm.* In some plants, such as peas and beans, the embryo absorbs the endosperm, and food is stored in the cotyledons. In nonflowering seed plants, a tissue called the *megagametophyte* serves as a place to store food. See **Seed**.

How plants reproduce

Plants create more of their own kind by either *sexual reproduction* or *asexual reproduction.* In sexual reproduction, a male sperm cell joins with a female egg cell to produce a new plant. Both the egg and the sperm cells contain *genes* (hereditary material). Genes determine many of the characteristics of a plant. A plant that is produced by sexual reproduction inherits genes from both parent plants. It is a unique individual and has traits that may be different from either parent. Asexual reproduction can occur in many ways. It often involves the division of one plant into one or more parts that become new plants. These plants inherit genes from only one parent and have exactly the same characteristics as the parent plant. This type of asexual reproduction is called vegetative propagation. Many plants reproduce both sexually and by vegetative propagation.

Sexual reproduction

Sexual reproduction in plants occurs as a complex cycle called *alternation of generations.* It involves two distinct generations or phases. During one phase of the life cycle, the plant is called a *gametophyte,* or *gamete-bearing plant.* In most species of plants, the gametophyte is barely visible and is rarely noticed by people. It produces *gametes*—that is, the sperm and egg cells. It may produce sperm cells or egg cells, or both, depending on the species of plant. When the sperm and egg cells unite, the fertilized egg develops into the second phase of the plant's life cycle. In this phase, the plant is called a *sporophyte* or *spore-bearing plant.* When people see a plant it is most often the sporophyte phase. Sporophytes produce tiny structures called *spores* through a process of cell division called *meiosis.* The spores form in closed capsulelike structures called *sporangia.* Gametophytes develop from the spores, and the life cycle begins again.

In seed plants, which include flowering and cone-bearing plants, alternation of generations involves a series of complicated steps. Among these plants, only the sporophyte generation can be seen with the unaided eye. Spores are produced in the male and female reproductive organs of a plant. The spores grow into gametophytes, which remain inside the plant's reproductive organs.

In flowering plants, the reproductive parts are in the flowers. A plant's stamens are its male reproductive organs. Each stamen has an enlarged tip called an *anther.* The pistil is the plant's female reproductive organ. The ovary, which forms the round base of the pistil, contains the ovules. The anthers consist of structures called *microsporangia,* and the ovules contain structures called *megasporangia.* Cell divisions in the microsporangia and the megasporangia result in the production of spores.

In most species of flowering plants, one spore in each ovule grows into a microscopic female gametophyte.

Ken Brate, Photo Researchers

Many flowering plants are pollinated by bees and other animals. Grains of pollen become stuck to the animals, which carry them from flower to flower during their search for food.

Runk/Schoenberger from Grant Heilman

Conifers produce pollen grains that are carried by the wind from male cones to female cones. In this photograph, a male cone of an Austrian pine is shedding pollen.

w flowering plants reproduce

Fwering plants begin reproduction by a process called *pollination*. The process starts when a plen grain from the anther of a stamen reaches the stigma of a pistil. A long, hairlike pollen tube tn grows from the pollen grain to an ovule in the ovary. Sperm cells then move through the plen tube to the ovule. When one fertilizes an egg cell, a seed begins to develop.

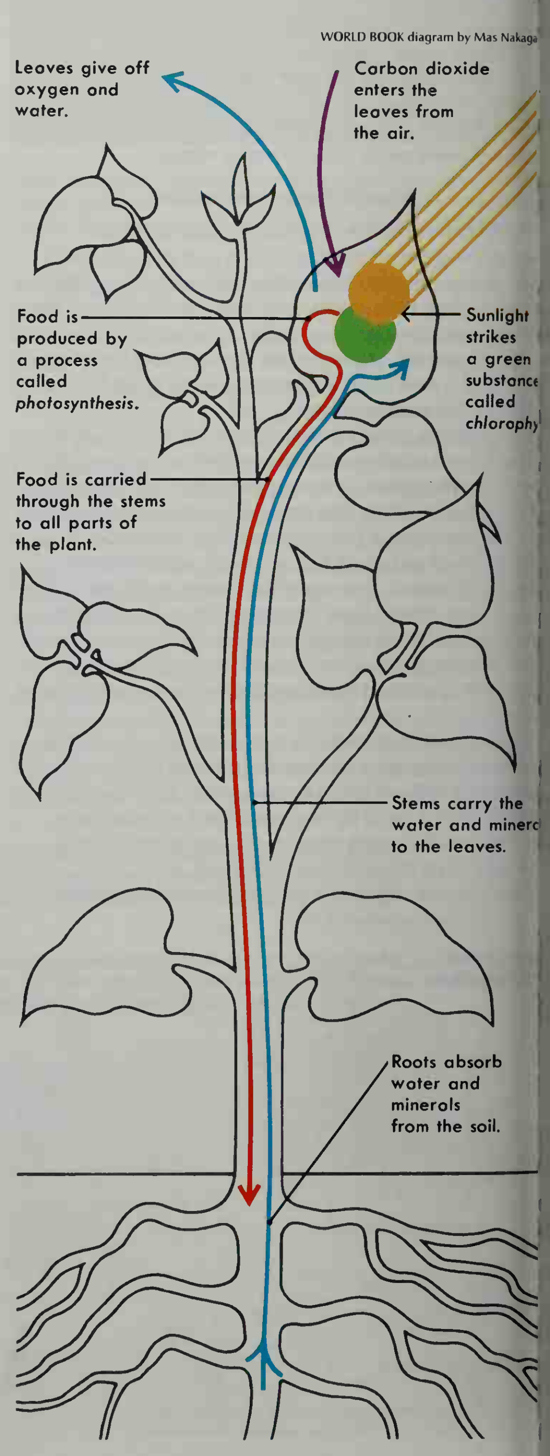
How plants grow

Plants can be divided into two groups, based on how they get their food. All green plants are called *autotrophs.* They contain chlorophyll, which enables them to capture the sunlight used in producing the food and other materials they need for growth. Other kinds of plants, called *heterotrophs,* lack chlorophyll and cannot make their own food. They are either parasites or saprophytes.

This section discusses the four major processes that take place in the growth of most kinds of green plants. These processes are (1) *germination,* (2) *water movement,* (3) *photosynthesis,* and (4) *respiration.* The section also discusses how a plant's heredity and environment affect its growth.

Germination is the sprouting of a seed. Most seeds have a period of inactivity called *dormancy* before they start to grow. In most parts of the world, this period lasts through the winter. Then, after spring arrives, the seeds start to germinate.

Seeds need three things to grow: (1) a proper temperature, (2) moisture, and (3) oxygen. Most seeds, like most kinds of plants, grow best in a temperature between 65° F. (18° C) and 85° F. (29° C). The seeds of plants that live in cold climates may germinate at lower temperatures, and those of tropical regions may sprout at higher temperatures. Seeds receive the moisture they need from the ground. The moisture softens the seed coat, allowing the growing parts to break through. Moisture also prepares certain materials in the seed for their part in seed growth. If a seed receives too much water, it may begin to rot. If it receives too little, germination may take place slowly or not at all. Seeds need oxygen for the changes that take place within them during germination.

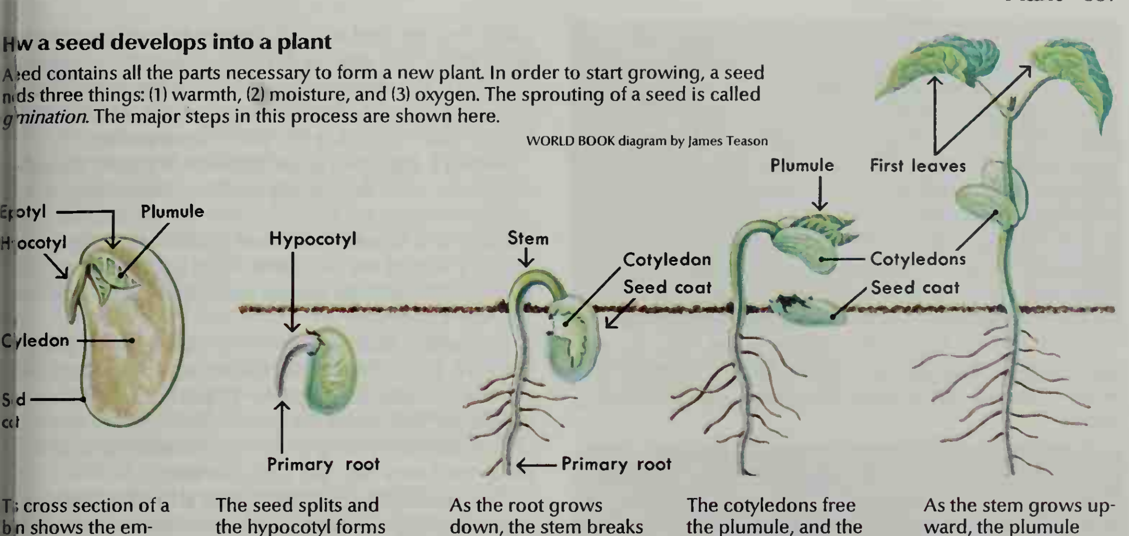


The embryo of a seed has all the parts needed to produce a young plant. It may have either one or more cotyledons, which digest food from the endosperm for the growing seedling. The seed absorbs water, which makes it swell. The swelling splits the seed coat, and a tiny seedling appears. The lower part of the seedling, called the *hypocotyl,* develops into the primary root. This root anchors the seedling in the ground and develops a root system that supplies water and minerals. Next, the upper part of the seedling, called the *epicotyl,* begins to grow upward. At the tip of the epicotyl is the *plumule,* the bud that produces the first leaves. In some plants, such as the many kinds of beans, the growth of the epicotyl carries the cotyledons above ground. In corn and other plants, cotyledons remain underground, within the seed. After a seedling has developed its own roots and leaves, it can make its own food. It no longer needs cotyledons to supply nourishment.

Most plants grow in length only at the tips of their roots and branches. The cells in these areas are called *meristematic* cells. They divide and grow rapidly and develop into the various tissues that make up an adult plant. In trees and other plants that increase in thickness, new layers of cells form between the bark and wood. This area is the *cambium.* New layers of cells are made as the cambium grows each year. These layers form the woody rings that enable people to tell the age of a tree.

Some kinds of plants, called *perennial* plants, live for many years. Most perennials produce seeds yearly.

Growth of a green plant



Green plants make the food they need by a process called *pho-tosynthesis.* This process, which occurs chiefly in the leaves, is triggered by chlorophyll. The chlorophyll interacts with water from the soil, carbon dioxide from the air, and light from the s to produce food. Most plants have special conducting tissue that carries food through the stems to all parts of the plant. Th food is needed for growth, repair, and storage.

Hw a seed develops into a plant

A ed contains all the parts necessary to form a new plant. In order to start growing, a seed n ds three things: (1) warmth, (2) moisture, and (3) oxygen. The sprouting of a seed is called *g mination.* The major steps in this process are shown here.

WORLD BOOK diagram by James Teason

T cross section of a b n shows the em- b in a seed coat.

The seed splits and the hypocotyl forms the primary root.

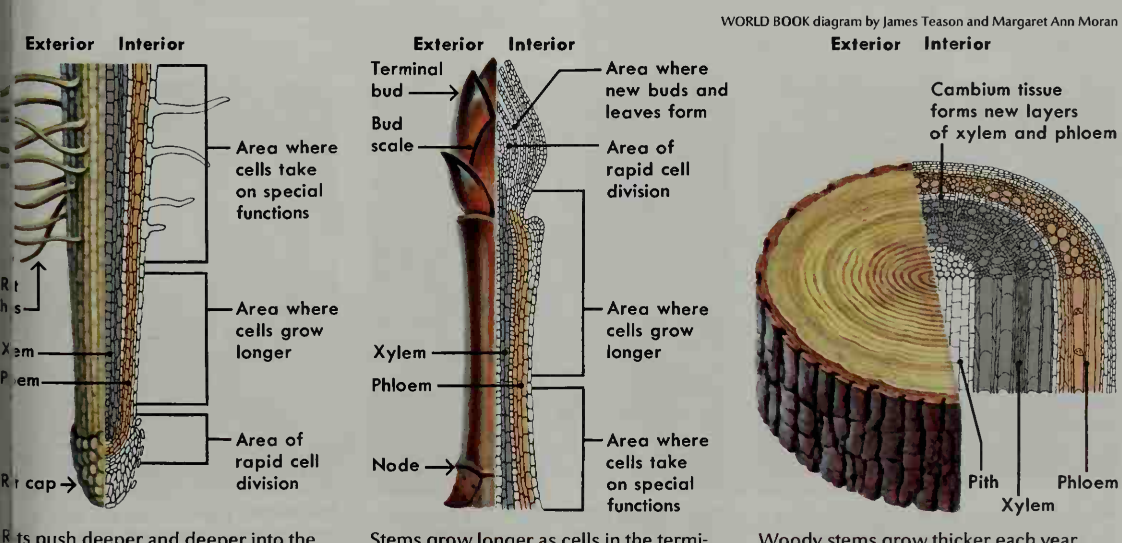
As the root grows down, the stem breaks through the soil.

The cotyledons free the plumule, and the seed coat drops off.

As the stem grows upward, the plumule forms the first leaves.

A nual plants live only about one year. *Biennial* plants li for two years. Most annuals and biennials produce s ds only once. See **Annual; Biennial; Perennial.**

Vater movement. Plants must have a continuous s ply of water. Each individual plant cell contains a l je amount of water. Without this water, the cells c ld not carry on the many processes that take place v hin a plant. Water also carries important materials f n one part of a plant to another.



Most water enters a plant through the roots. Tiny root h rs absorb moisture and certain minerals from the soil b a process called *osmosis* (see **Osmosis**). In many p nts, fungi that grow on the roots help the plants absorb water and minerals. In vascular plants—that is, plants with special conducting tissues—these materials are transported through the xylem tissue of the roots and stems to the leaves. There, water and minerals are used in making food. Water also carries this food through the phloem tissue to other parts of the plant.

Plants give off water through a process called *transpiration.* Most of this water escapes through the stomata on the surfaces of the leaves. Scientists estimate that corn gives off 325,000 gallons of water per acre (3,040,000 liters per hectare) by transpiration during a growing season. Some botanists believe this water loss prevents the leaves from overheating in sunlight.

w plants grow longer and wider

N st plants grow only at the tips of their roots and stems. Cells in these areas grow rapidly, form- i the various tissues that make up an adult plant. Trees and other plants that grow wider develop a w layer of tissue just below the bark each year. The growing parts of plants are shown here.

WORLD BOOK diagram by James Teason and Margaret Ann Moran

R ts push deeper and deeper into the s as cells just in back of the root cap d de and grow longer.

Stems grow longer as cells in the terminal bud divide rapidly. These cells will develop into buds, flowers, and leaves.

Woody stems grow thicker each year. New growth comes from the rapidly dividing cells that make up the cambium.

Photosynthesis is the process by which plants make food. The word *photosynthesis* means *putting together with light.* In green plants, sunlight captured by chlorophyll enables carbon dioxide from the air to unite with water and minerals from the soil and create food. This process also releases oxygen into the air. People and animals must have this oxygen to breathe.

Most photosynthesis takes place in small bodies called *chloroplasts* within the cells of plant leaves. These chloroplasts contain chlorophyll, which absorbs sunlight. Energy from the sun splits water molecules into hydrogen and oxygen. The hydrogen joins with carbon from the carbon dioxide to produce sugar. The sugar helps a plant make the fat, protein, starch, vitamins, and other materials that it needs to survive. See **Photosynthesis.**

Some plants, called *parasites* and *saprophytes,* have little or no chlorophyll and cannot produce their own food through photosynthesis. These plants must rely on outside sources for food. Parasites attach to living plants and take the nutrients they need from these plants. Saprophytes grow on dead and decaying organisms, or use organic substances produced by living organisms for food.

Mistletoe and dodder are common parasites found in many parts of the world. Mistletoe grows on the trunks and branches of many trees. It is called a *partial parasite* because it also makes some of its own food. Indian pipe is a saprophyte that grows near fungi. It uses organic materials produced by fungi for food. A plant called giant rafflesia is a parasite that grows on the roots and stems of other plants. It bears the largest flower of any known plant. Rafflesia flowers may grow over 3 feet (91 centimeters) wide.

Respiration breaks down food and releases energy for a plant. The plant uses the energy for growth, reproduction, and repair. Respiration involves the breakdown of sugar. Some of the products resulting from this breakdown combine with oxygen, releasing carbon dioxide, energy, and water. Unlike photosynthesis, whic takes place only during daylight, respiration goes on day and night throughout the life of a plant. Respiratio increases rapidly with the spring growth of buds and leaves, and it decreases as winter approaches.

Factors affecting plant growth. A plant's growth i shaped by both its heredity and its environment. A plant's heredity, for example, determines such characteristics as a flower's color and general size. These hereditary factors are passed on from generation to gen ation. Environmental factors include sunlight, climate, and soil condition.

Hereditary factors. Within the nucleus of all plant cells are tiny bodies called *chromosomes* that contain hereditary units called *genes.* These bodies contain "ir structions" that direct the growth of the plant. As the cells divide and multiply, the "instructions" are passed on to each new cell. See **Cell; Heredity.**

Substances made within a plant also play a part in regulating plant growth. These substances, called *hormones,* control such activities as the growing of roots and the production of flowers and fruit. Botanists do n know exactly how all plant hormones work. But they have learned that certain hormones, called *auxins,* affe the growth of buds, leaves, roots, and stems. Other growth hormones, called *gibberellins,* make plants grow larger, cause blossoming, and speed seed germi nation. Still other hormones called *cytokinins* make plant cells divide.

Environmental factors. All plants need light, a suitable climate, and an ample supply of water and miner from the soil. But some species grow best in the sun, and others thrive in the shade. Plants also differ in the amount of water they require and in the temperatures they can survive. Such environmental factors affect the rate of growth, the size, and the reproduction of all plants.

The growth of plants also is affected by the length o the periods of light and dark they receive. Some plants

How nongreen plants get their food

Nongreen plants cannot make their food. *Parasites* get food from other living things. *Saprophytes* live on decaying organisms or on substances made by living organisms.

Edward S. Ross

Mistletoe, *above,* grows on trees. It is a partial parasite because it takes water and minerals from trees but makes food in its own leaves.

Edward S. Ross

The dodder plant, *above,* is a parasite. This plant grows in tangled masses. It gets its food by inserting specialized roots called *suckers* into other plants.

iruding lettuce and spinach, bloom only when the
p*toperiod* (period of daylight) is long. Such plants are
c.ed *long-day* plants. On the other hand, asters, chry-
s.themums, and poinsettias are *short-day* plants. They
bom only when the dark period is long. Still other
pnts, among them marigolds and tomatoes, are not af-
fted by the length of the photoperiod. They are called
d-neutral plants.

'lants also are affected in other ways by their environ-
nnt. For example, a plant may display a bending move-
nnt called a *tropism.* In a tropism, an outside *stimulus*
(fce) causes a plant to bend in one direction. A plant
ny have either a *positive* or a *negative* tropism, de-
pnding on whether the plant bends toward or away
fm the stimulus. Tropisms are named according to the
snuli that cause them. *Phototropism* is bending caused
t light, *geotropism* is caused by gravity, and *hydrotro-*
m is caused by water.

A plant placed in a window exhibits positive photot-
rpism when its stems and leaves grow toward the
surce of light. Roots, on the other hand, display nega-
te phototropism and grow away from light. However,
rots demonstrate positive geotropism. Even if a seed or
llb is planted upside down, its roots grow down-
rd—toward the source of gravity. The stem of the
ne bulb shows negative geotropism by growing
ward—away from the source of gravity. Hydrotropism
curs chiefly in roots and is almost always positive. See
opism.

Some plants are affected by being touched. When the
nsitive plant, *Mimosa pudica,* is touched, its leaflets
ickly fold and its branches fall against its stem. A
ange in pressure within certain cells of the plant
uses this action. After the stimulus has been removed,
e plant's branches and leaflets return to their original
sition.

Henry M. Cathey, U.S. Department of Agriculture

The amount of daylight received by a plant affects its growth. The petunias above are the same age. They have received, *from left to right,* 8, 12, 16, 20, and 24 hours of light per day.

Runk/Schoenberger from Grant Heilman

Hormones can affect plant growth. In the experiment shown above, the plant cutting at the left was treated with the hormone *naphthalene acetic acid.* The cutting on the right was untreated.

Grant Heilman

eotropism, the effect of gravity on plants, can be shown by lanting corn kernels upside down, *above.* Roots have positive eotropism and grow downward toward the source of gravity.

Walter Dawn

Phototropism is a bending movement caused by light. The stem of the coleus plant shown above demonstrates positive phototropism. It is growing toward a fixed source of light.

How plants change

Plants—like animals—compete with one another for sunlight, water, and other necessities of life. Some plants—like some animals—are better able than others to grow and reproduce. After thousands of years, those that survive may differ greatly from their ancestors. The surviving plants have adapted to their environment through a process called *natural selection* or survival of the fittest (see **Natural selection**).

This section traces the early history of plants and discusses important forms of plant adaptation for water storage and seed *dispersal* (scattering). This section also describes an unusual group of plants that adapted in such a way that they capture and eat insects. It ends with a discussion of some of the ways that people have changed plants.

Early plants. The first land plants appeared on the earth over 430 million years ago during the Paleozoic Era. These plants were very simple and did not resemble any of the plants we see today. They probably had a sticklike plant body and lacked the specialized water-conducting tissue of vascular plants. Many botanists believe these early land plants are the ancestors of primitive vascular plants. The first vascular plants, called *Rhyniophytes,* did not have leaves or roots. They consisted of both stems that grew along the ground and stems that grew upright with Y-shaped branches. These plants probably grew as tall as 2 to 3 feet (60 to 90 centimeters).

Larger plants called *Trimerophytes* may have developed from the Rhyniophytes. The Trimerophytes had a more complex plant body with numerous stems and branches. But they did not have leaves, and only some of them may have had simple roots. Other small vascu plants called *Zosterophyllophytes* appeared shortly aft the Rhyniophytes and also may have descended from them. Some botanists believe Trimerophytes and Zosterophyllophytes are the ancestors of all vascular plan that exist today. They think that ferns, horsetails, and seed-bearing plants *evolved* (developed through progressive change) from Trimerophytes about 408 millio to 360 million years ago. Club mosses, quillworts, and selaginellas are believed to have evolved from Zostero phyllophytes about that same time.

When the first vascular plants began to grow succes fully on much of the land, life on earth was very differe than it is today. No leaves rustled in the breeze, few insects crawled about, and no *vertebrates* (animals with backbones) lived on land. However, as conditions on th earth changed, new plants and animals developed. Du ing the Carboniferous Period, about 360 million to 286 million years ago, more complex and larger vascular plants evolved. Great forests of lycopsid trees, ferns, horsetails, and early seed plants covered the earth. The huge plants of this period died and accumulated in vas swamps. They later formed large coal deposits. Most of the coal found in the eastern and midwestern United States is made up of these plants.

WORLD BOOK illustration by James Teas

About 410 million years ago, forests began to grow in swampy regions of the world. The plants of these early forests included the ancestors of present-day club mosses, horsetails, and ferns. The first amphibians and insects also appeared about the same time.

Paul Meyer, Tom Stack & Assoc.

Desert plants have many features that enable them to survive in extremely dry areas. The barrel cactuses, *shown here,* store water from infrequent rains in their thick, fleshy stems.

ymnosperms became the most plentiful plants dur-
i the Mesozoic Era, beginning about 248 million years
a. Conifers, cycads, and ginkgoes were among the
st important plants. They served as food for the great
osaurs that roamed the land during this period.
ny now-extinct types of gymnosperms also flour-
ed. The first angiosperms, or flowering plants, ap-
ared near the end of the Mesozoic Era. Among them
re magnolias, sycamores, willows, water lilies, and
ny other present-day flowering plants.

During the Cenozoic Era, beginning about 65 million
ars ago, forests of angiosperms covered much of the
pical and temperate regions of the earth. Grasslands
d large grazing animals began to appear late in the
nozoic Era. Some scientists believe that humanlike
atures appeared on the earth about 5 million years
o and lived in the regions between the forests and
asslands.

Water storage. Through the years, many species of
ants have developed special methods for collecting
d storing water that enabled them to survive in areas
little rainfall. Some cactuses, for example, have roots
at spread over large areas just below the surface of
e ground. These roots quickly absorb water from the
ht rains and sudden floods that occur on the desert.
ctuses store the water in their fleshy stems.

Through natural selection, the leaves of cactuses
olved into spines. As a result of this adaptation, cac-
ses have less green surface than do most plants of
eir size—and they lose less water through transpira-
n. Because cactuses have such specially shaped
aves, they carry out photosynthesis in their stems. Dur-
g photosynthesis, cactuses use their stored water sup-
y if water from their roots is not available.

Plants of the tundra also have adapted to the dry con-
tions created by frozen soils. The surfaces of their
aves are especially resistant to water loss. They are ei-
er hard and glossy or very hairy. In addition, tundra
ants grow close to the ground, where they are covered by snow and thus protected from the strong winds of these regions.

Seed dispersal. Seeds play an important part in the distribution of plants to nearly every part of the world. If seeds simply fell to the ground, all the plants of each species would be found in the same area. People also have helped spread seeds by taking food crops and certain other plants wherever they have settled.

lants that eat insects

sect-eating plants grow in soil that lacks important minerals, especially nitrogen. Special organs
able these plants to trap and digest insects whose bodies contain the minerals.

Lincoln Nutting, NAS

er, tube-shaped leaves.

Ross E. Hutchins

A sundew plant has sticky hairs on its leaves that trap insects and then cover them with digestive fluids.

Howard A. Miller, Sr., NAS

The leaves of Venus's-flytrap close quickly on an insect. They open after the victim has been digested.

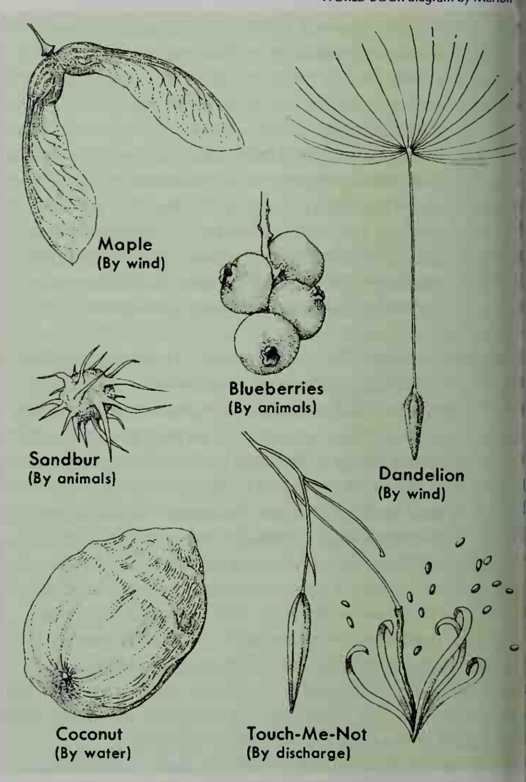
Seeds have many features that have helped them be scattered across large regions. The wind carries many seeds, including the winglike ones of the maple tree and the fluffy seeds of dandelion and milkweed plants. Some seeds, such as those of the coconut, may float on water from one land area to another.

Animals also help distribute seeds. Some plants have burs and sticky substances which cling to the fur or feathers of animals that migrate from one region to another. Many kinds of animals eat berries and fruits but do not digest the seeds. The seeds are dispersed as part of the body waste of these animals.

A few species of plants distribute their own seeds. For example, a wild flower called the touch-me-not shoots out its seeds at the slightest touch.

Insect-eating plants grow chiefly in areas where the soil lacks an adequate supply of important minerals, especially nitrogen. These plants have adapted so that they can obtain needed minerals by trapping and digesting insects in their leaves. These *carnivorous* plants also manufacture their own food by photosynthesis. Insect-eating plants include the pitcher plant, the sundew, and Venus's-flytrap.

Pitcher plants have tube-shaped leaves that collect rain water. Sweet substances around the rim of each tube attract insects to the plant. After an insect enters the tube, tiny, downward-pointing hairs keep the struggling victim from escaping. In time, the insect becomes exhausted, slides into the water, and drowns. The plant then digests the insect by means of a fluid secreted by glands located in the leaves.



The leaves of the sundew plant grow hairs that give off a sticky substance that contains digestive juices. When an insect gets stuck on this substance, the hairs wrap around it. More fluid covers and suffocates the insect, which is then gradually digested by the sundew plant.

Venus's-flytrap has hinged leaves that trap insects.

How seeds are dispersed

Seeds have a variety of features that help them to be scattered to almost every part of the world. People and animals also help disperse seeds in a number of ways.

WORLD BOOK diagram by Marion

The inside of each leaf has hairs, and the rim is edged with sharp bristles. When an insect lands on the hairs, the two halves of the leaf close like a trap, with the bristles interlocking. After the plant has digested the insect, the leaves open up again.

How people have changed plants. People began to play an important role in changing plants about 10,000 years ago, when they learned to raise food by farming. Early farmers noted that some plants grew better than others. They saved seeds from these plants to grow new ones. The basic food crops of the world were developed in this way. For example, the Indians of the Americas developed tiny ears of wild corn into large cobs with many kernels. By the time Christopher Columbus reached the New World in 1492, this improved corn was being raised over large areas of the Americas.

The scientific study of plants has greatly aided our attempts to make plants more useful and attractive. For example, an Austrian monk named Gregor J. Mendel conducted experiments on garden peas in the mid-1800's that laid the foundation for the field of *genetics,* the science of heredity. Using the laws of genetics, scientists have greatly increased the yield of such crops as corn, rice, and wheat. They also have developed plants that can resist the attacks of various diseases and insects. In 1970, Norman E. Borlaug, an American agricultural scientist, received the Nobel Peace Prize for developing high-yield, disease-resistant wheat.

Michael D. Coe

Large ears of corn were developed by the American Indians from tiny cobs of wild corn, *above.* Today, botanists seek ways to improve crop yields and develop disease-resistant plants.

Plant enemies

Various kinds of plant enemies attack and injure al-
[illegible]st all species of plants throughout the world. Dis-
[illegible]es and insect pests rank as the major enemies of
[illegible]nts. They cause serious, widespread damage to agri-
[illegible]ltural, garden, and ornamental plants, many of which
[illegible]ve lost the natural defenses present in wild plants. In
[illegible] United States, diseases, insects, and other plant ene-
[illegible]es cause crop losses totaling about $30 billion yearly.
[illegible]seases reduce the nation's total annual crop produc-
[illegible]n by 10 to 15 per cent, and insects reduce it by about
[illegible]other 15 per cent.

Widespread outbreaks of plant diseases can cause [illegible]nine. During the 1840's, about 750,000 people in Ire[illegible]nd died after a fungus disease destroyed the nation's [illegible]tato crop. Other diseases have killed large numbers [illegible] certain species of plants. For example, a fungus dis[illegible]se called *chestnut blight* has destroyed the chestnut [illegible]e throughout North America. Insects also severely [illegible]mage large numbers of plants. Swarms of grasshop[illegible]rs have destroyed entire crops of alfalfa, cotton, and [illegible]rn. Gypsy moths have damaged forests in the North[illegible]stern United States and are spreading to other areas. [illegible] addition, many plants are injured or killed by animal [illegible]sts, including mites, rabbits, and rodents.

Diseases in plants are caused by many kinds of mi[illegible]oorganisms, including certain fungi, bacteria, viruses, [illegible]d small worms called *nematodes.* Fungi cause more [illegible]ant diseases than the other microorganisms. Viruses [illegible]so infect plants with serious diseases.

Certain conditions in the environment can damage [illegible]ant tissues and weaken plants so that they are more [illegible]sily infected by disease-causing microorganisms. [illegible]uch conditions include air pollution, unusually high or [illegible]w temperatures, lack of proper nutrients in the soil, [illegible]d low levels of light or oxygen.

Plant diseases may affect every part of the plant. Many [illegible]iseases interfere with the plant's ability to carry out [illegible]hotosynthesis by damaging leaves or by blocking the [illegible]ow of water or nutrients to stems and leaves. Fungi, [illegible]acteria, or viruses may invade plant tissues and kill cells in a small area. For example, dead spots on leaves and fruits, or yellowing and death of leaves at the edges, indicate places where microorganisms have killed plant cells. Abnormal growths, such as *galls* and *knots,* on roots, stems, and other parts of the plant also signal places of infection. Fungi or bacteria that invade the roots, stems, and leaves can prevent xylem tissue from transporting water throughout the plant. As a result, the leaves, stems, and flowers may wilt or suddenly die. In addition, fungi may secrete *toxins* (poisons) that cause large parts of the plant to die.

Fungal diseases are spread from plant to plant by the spores of the fungi. These spores are carried by insects, rain, wind, and even people. Some bacteria and viruses are spread in the same way. Nematodes not only cause certain diseases but also transmit viruses from diseased to healthy plants. Some bacteria and fungi live on plant refuse in the soil and infect healthy plants. Others are carried on the seeds of plants.

Some diseased plants cause serious illness when eaten by human beings and animals. For example, a fungus called *ergot* infects wheat, barley, and rye. It produces chemicals that can cause *ergotism,* an illness that afflicts people who eat bread made from the infected grain. Other fungi, if enough are present on food or animal feed, produce harmful chemicals called *mycotoxins.* Scientists are conducting extensive research on these chemicals, some of which may cause cancer.

Nutrient deficiencies. Plants suffer from *nutrient deficiencies* when they cannot obtain certain minerals and chemicals from the soil. Nutrient deficiencies are harmful to plants in a number of ways. They may cause changes in leaf color, reduction in the size of leaves, dead spots on leaves and stems, reduced growth, and wilting. Each symptom often can be linked to the lack of a specific chemical, usually nitrogen or potassium.

Plants may also be affected by *chemical toxicity* when the soil contains too much of certain chemicals or minerals. For example, most plants require very small amounts of zinc, iron, and copper. But people some-

[illegible] **bacterial disease called fire blight** has killed most of the [illegible]eaves of the pear tree at the left. The photograph at the right [illegible]hows hundreds of the microscopic fire blight bacteria.

James D. Miller, Agricultural Research, USDA (North Dakota State University)

Runk/Schoenberger from Grant Heilman

A fungal disease called black stem rust attacks wheat stalks, *left.* A photograph of an infected stalk seen under a microscope, *right,* shows the reddish-black fungal spores.

times introduce excessive amounts of these substances into the soil during the mining and smelting of ore. As a result, large numbers of plants are killed. Zinc also may accumulate in the soil below fences that are coated with the mineral to prevent them from rusting. The zinc builds up in a narrow strip of soil and eventually destroys many of the plants growing there.

Some soils are naturally too rich in metals. For example, areas of *serpentine,* a volcanic rock that contains heavy metals, are common in western North America. These areas form *barrens* where few plants survive.

Pests. Insects damage or destroy plants in a number of ways. Insects with chewing mouthparts, such as beetles and grasshoppers, eat holes in leaves and stems. Other insects have piercing and sucking mouthparts with which they pierce plants and consume the plant juices. Some insects feed on flowers and fruit. The destruction of leaves by insects affects the growth and yield of crops because photosynthesis is reduced. In addition, wounds made in plants by insects provide places for disease-causing organisms to enter the plants easily.

Some insects secrete poisons or other chemical substances while feeding. These secretions may cause galls on leaves or roots or give leaves a "burned" appearance. Other insects interrupt the flow of food and water in plants by feeding on phloem and xylem tissue.

Mites, which have sucking mouthparts, injure plants by feeding on them. Rabbits and rodents gnaw on plants. Some kinds of rodents burrow into the soil and feed on the roots, seeds, and bulbs of plants.

How plants protect themselves. Insects and many other animals eat plants. To avoid being eaten, many species of plants have developed physical and chemical defenses. Many plants also protect themselves through the timing of when they produce flowers and fruits.

Physical defenses of plants include such structures as spines, thorns, and prickles. These structures, which are usually modified leaves or branches, prevent attacks by large plant-eating animals. Heavy coatings of wax or dense, stiff hairs on leaves and stems may repel smaller

Jane Burton, Bruce Coleman Ltd.

Insects damage large numbers of plants. Locusts, shown here devouring the leaves of a corn plant, are among the most destructive pests. Swarms of locusts can destroy an entire crop.

E. R. Degginger, Earth Scen

The leaves and stems of poison ivy, *above,* contain a poisonous oil that is extremely irritating to the skin. The oil helps protect the plant from animals and human beings.

animals, especially insects. Some plants, including grasses, accumulate a hard mineral called *silica* in their leaves. The silica makes the leaves difficult for animals to chew and rapidly wears down their teeth.

Certain species of plants obtain protection from animal enemies through a relationship called *mutualism.* In this relationship, the plant provides a special type of food for a particular group of insects. The insects, in turn, protect the plant from other animals. One example of plant-insect mutualism is the relationship between ants and acacia trees in some dry regions of the world. Ants live in hollow thorns on the acacia trees, and the leaves of the trees release a sugar solution for the ants to eat. In return, the ants clear the ground around each tree and attack any other animals that enter the cleared area or that land on the trees.

Plants have a wide variety of chemical defenses against animals. The leaves and fruits of citrus plants produce sticky, strong-smelling oils that discourage many insects. Many plants contain chemicals that have an unpleasant taste or are poisonous. Such plants include nightshade, foxglove, yew, and many weeds.

Insects can quickly become immune to the chemicals plants produce. In some cases, certain kinds of insects develop a means of breaking down the toxic compounds produced by the plants. As a result, plants continually develop new chemical compounds by altering existing ones. Some scientists describe this process as a biological "arms race" between plants and their predators. In other cases, the "arms race" between an insect and plant has resulted in a unique relationship. For example, plants in the milkweed family produce a milky sap that contains poisonous chemicals. The chemicals prevent most insects from eating the plants. However, caterpillars of monarch butterflies are able to eat milkweed plants and store the poison in their bodies. The poison makes monarch butterflies distasteful and so protects them from many predators.

Camouflage helps protect certain plants from animals that feed on them. This photograph shows five living rock cactuses. Their color and shape make them barely distinguishable from surrounding rocks.

© Breck P. Kent, Earth Scenes

Many plants try to ensure the survival of their seeds rough the timing of flower and fruit production. Some ants produce flowers and fruits very early in the grow-g season, when insect populations are small. Other ants produce so many seeds that animals cannot eat em all. For example, oak trees produce a great num-er of acorns every few years. When acorns are abun-nt, squirrels and other animals cannot eat all of them id some acorns survive to grow into new oak trees. In her years, oak trees do not produce an abundance of corns and thus prevent animals from relying on acorns r food. If the trees produced a surplus of acorns each ear, the animal population would increase and all the corns would be eaten.

Control of diseases and pests. People fight plant iseases and pest damage by means of (1) genetic meth-ds, (2) physical methods, (3) sanitation, (4) chemicals, (5) biological control, and (6) quarantine laws. Genetic methods include the development of resistant varieties of plants by plant breeders. Breeders cross resistant plants with other varieties of the same species to develop new varieties that combine resistance with high yield and other desirable characteristics. Such efforts by plant breeders have resulted in the development of high-yield, rust-resistant wheats, for example.

Physical methods include such barriers against plant pests as sticky bands of paper that trap insects, and wire guards to keep rodents away. Plant growers also gather and destroy insects and insect eggs found on plants. Crop rotation and plowing help prevent plant enemies from overpopulating the soil.

Sanitation includes destroying diseased plants and disinfecting planting equipment. In addition, refuse is removed from a growing area. This removal eliminates places where insects and disease-causing organisms may reproduce.

Chemicals make up the largest part of almost every program to control plant enemies. Diseases and pests may attack suddenly, and chemicals may be the only means of saving the plants. Many chemicals protect plants from diseases and pests. They include bactericides, fungicides, insecticides, nematocides, and rodenticides. In the United States, such chemicals must be approved by the Environmental Protection Agency before they can be marketed.

Biological control involves the use of natural processes to fight the insects and disease organisms that attack plants. For example, certain bacteria and viruses that cause diseases in beetles and caterpillars may be introduced into an area to control those insects. Similarly, animals that prey on insects may be introduced to control plant enemies. Another example of biological control is the capture of insects in traps baited with *sex attractants,* the natural chemicals that insects secrete to attract mates.

Quarantine laws regulate the shipment of plants between countries and, in the United States, between states. These laws require inspection of plants to prevent the introduction and spread of plant diseases and insect pests. William A. DiMichele

Raymond F. Hillstrom

Chemicals play a major role in controlling plant enemies. A crop duster, *above,* can rapidly spray an entire field with chemicals that protect against various diseases and pests.

Classification of plants

Botanists classify plants by grouping them according to their shared similarities. Such an arrangement provides a logical way to organize information about plants and show how different plants are related to each other.

Most botanists group plants by their overall appearance, their internal structure, and the form of their reproductive organs. However, not all botanists agree on how plants should be divided, and there are a number of different classifications of the plant kingdom. One frequently used classification system is described below. This system classifies plants into 2 large groups or div sions. A division is the same grouping as a phylum in the animal kingdom.

One division, Bryophyta, is made up of *nonvascular plants.* These plants lack xylem and phloem tissues tha carry water and food from one part of the plant body t another. The other division, Tracheophyta, consists of *vascular plants* that contain these specialized tissues. Within the divisions are several smaller groupings, including subdivisions, classes, subclasses, and orders.

WORLD BOOK illustrations by Marion Pahl and Paul D. Turnba

Nonvascular plants

Division Bryophyta

Liverworts, hornworts, and mosses make up this division of plants. These plants reproduce by means of spores and lack true leaves, stems, or roots. Most live in moist areas. However, some mosses can withstand severe temperatures and are found in Arctic or desert regions.

Class Hepaticae

Liverworts make up this class. These small plants may be flat and ribbon-shaped or leafy. They grow close to the ground.

Class Anthocerotae

Hornworts usually grow only $\frac{3}{8}$ to $\frac{3}{4}$ inch (1 to 2 centimeters) across. The gametophyte is ribbonlike. Spores are contained in tubular sporangia that grow continuously from the sporangium base.

Class Musci

True mosses make up this class. Stems may be erect or horizontal and bear many leaflike growths. They seldom grow over 8 inches (20 centimeters) long.

Leafy liverwort (Hepaticae)

Hornwort (Anthocerotae)

Moss (Musci)

Vascular plants

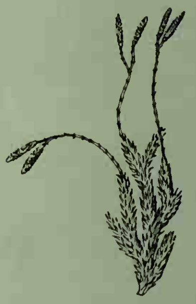
Division Tracheophyta

Tracheophytes are the vascular plants. All have two kinds of special tissues–*xylem* and *phloem.* Xylem tissue cells carry water from the roots to the leaves. Phloem tissue cells carry sugars made during photosynthesis in the leaves to other parts of the plant. Tracheophytes occur in most parts of the world.

Subdivision Lycophytina

These plants, which include club mosses, iseotopsids, and selaginellas, have leaves with a single central vein. Spores are produced in sporangia that grow in the stem-leaf nodes or on the leaves. The sporangia are distinctly kidney shaped. Plants in this subdivision tend to grow in moist, shady areas.

Class Lycopodiopsida



Lycopodiopsids are the club mosses and ground pines. Many species have stems that produce needlelike leaves. Spores are often tightly clustered at the tips of branches. Lycopodiopsids commonly grow on forest floors.

Class Selaginellopsida

Selaginellas produce separate male and female spores. They are leafy and usually delicate in construction. Though most selaginellas live in moist places, one kind, the "resurrection plant," occurs in desert environments.

Class Isoetopsida

Isoetopsids produce two kinds of spores, one male and one female. These small plants have grasslike leaves and live in wet, sometimes flooded places. During the Carboniferous Period, about 360 to 286 million years ago, some isoetopsids were large trees.

Club moss (Lycopodiopsida)

Subdivision Euphyllophytina

Euphyllophytes include most of the vascular plants. Their leaves usually have many veins, and their reproductive organs and internal structures differ from those of the Lycophytina plants.

Class Psilopsida

The plants in this class are called whisk ferns or fork ferns. They have many slender, highly branched aerial stems by which the plants spread. They reproduce from spores. These rare plants are found in tropical and subtropical regions.

Class Sphenopsida

Living sphenopsids are known as horsetails or scouring rushes. They have small leaves that occur in whorls at the nodes on the stem. Stems are hollow except at the nodes, giving them a jointed appearance. They grow 2 to 3 feet (61 to 91 centimeters) tall and reproduce by means of spores. During the Carboniferous Period, sphenopsids made up a much larger group that included trees.

Class Pteridopsida

This class includes the ferns. Most ferns have large leaves called *fronds.* They reproduce by means of spores. Ferns are commonly seen on forest floors, but tropical fern trees may grow more than 65 feet (20 meters) high. Some floating aquatic ferns have leaves only about 1 inch (2.5 centimeters) long. Next to the flowering plants, ferns are the most diverse group in the division Tracheophyta.

Class Gymnospermopsida

Gymnosperms reproduce by means of *naked,* or uncovered, seeds. Many gymnosperms are evergreens with a wide variety of leaf structures. The class consists of conifers, cycads, ginkgoes, and gnetaleans.

Order Coniferales

Most conifers are evergreen trees or shrubs with needlelike or scalelike leaves. Almost all conifers bear their seeds in woody cones.

Order Cycadales

Cycads grow fernlike leaves. Their seeds are borne in large cones. Many species have unbranched, erect stems, while others have partially underground stems called *tubers.* Some cycads are trees.

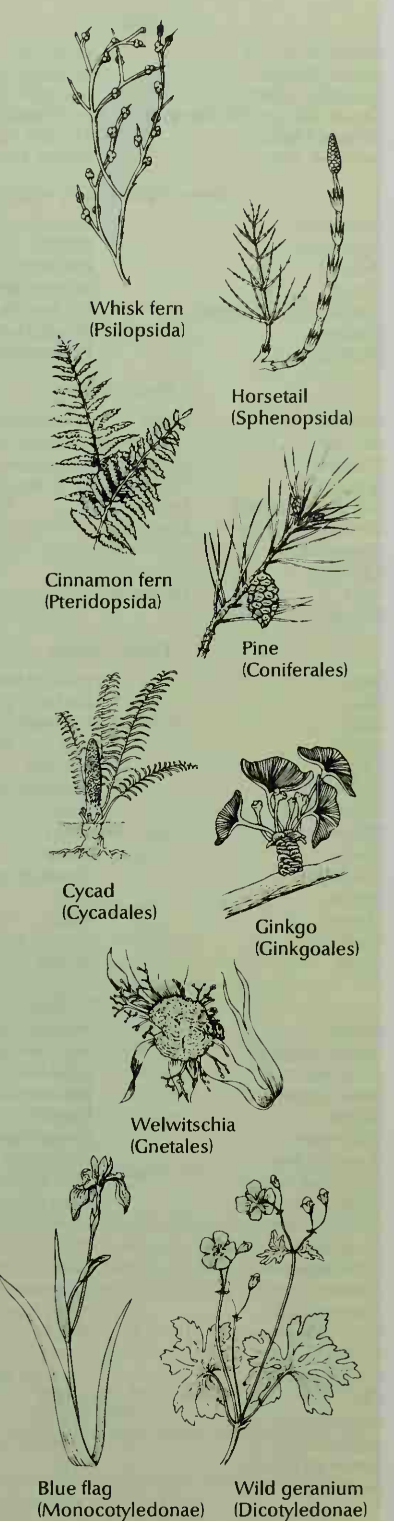
Order Ginkgoales

Ginkgoes are trees with fan-shaped leaves. They bear fleshy seeds at the end of short branches. The seeds are not in cones. Only one species of ginkgo exists today.

Order Gnetales

Gnetaleans are closely related to flowering plants and share many characteristics with them. Gnetalean seeds are borne in complex cones. Living forms vary widely in appearance and inhabit deserts and tropical rain forests.

Class Anthopsida



Flowering plants, or angiosperms, make up this class. All angiosperms reproduce by means of covered seeds. They bear their sexual organs in flowers. After fertilization, the ovary grows into a fruit that encloses the seeds. Angiosperms are the most diverse group of plants, growing from the tropics to the polar regions. They are divided into two subclasses–Monocotyledonae and Dicotyledonae.

Subclass Monocotyledonae

Monocots have seeds with only one *cotyledon* (seed leaf). The main veins in the leaves of these plants usually run parallel to each other. Flower parts usually occur in multiples of three.

Subclass Dicotyledonae

Dicots have seeds with two cotyledons. Their leaves have a complex system of veins. Dicot flower parts usually occur in multiples of four or five.

Plant quarantine laws regulate the movement both of plants and of other materials that may carry a plant disease or insect pest. The reason for the quarantine is to keep the disease or insect from spreading from infested areas. Some plant quarantine laws list plants that may not be shipped in and out of a locality. Such laws may also give directions for moving, packing, and labeling.

In a quarantine, officials may examine all plants at the border of the quarantined area and keep out the dangerous types. Other laws merely require an inspection of the plants or the place where they were grown.

Foreign plant quarantines control the shipping of plants from other countries. Such quarantines include those intended to keep out citrus canker disease, the Mediterranean fruit fly, and the khapra beetle. Domestic quarantines control plant movements from place to place within the country. They protect against stem rust, the gypsy moth, the Japanese beetle, the pink bollworm, and the white-fringed beetle.

In the United States, local, state, and federal governments may quarantine plants. The Animal and Plant Health Inspection Service helps enforce quarantines of plants that may carry diseases or insect pests.

Plantagenet, *plan TAJ uh niht,* was the family name of a line of kings that ruled England from 1154 to 1399. These kings descended from the marriage of Matilda, daughter of King Henry I, to Geoffrey, count of Anjou, France. Geoffrey was nicknamed *Plantagenet* because he wore a sprig of the broom *(genet)* plant in his cap. Numerous historians also call these kings *Angevins,* meaning *from Anjou.*

The Plantagenet dynasty began with Henry II, son of Matilda and Geoffrey. Henry ruled from 1154 to 1189 over England and vast possessions in France. He centralized the English government, established peace and order, and founded the English common law system. His son Richard the Lion-Hearted led the Third Crusade and ruled from 1189 to 1199. Richard's brother John succeeded him and ruled from 1199 to 1216. John lost most of England's French possessions. He was forced to grant Magna Carta in 1215 (see **Magna Carta**).

John's son Henry III ruled ineffectively from 1216 to 1272. Henry's son, Edward I, ruled from 1272 to 1307. He conquered Wales, invaded Scotland and proclaimed himself its king, and improved the English government and legal system. Edward's son Edward II lost Scotland. In 1327, he was forced by some of England's nobles to give up his throne and then was murdered. His son Edward III ruled from 1327 to 1377 and began the Hundred Years' War with France.

After Edward III's grandson Richard II was deposed in 1399, the Plantagenets split into the houses of Lancaster and York. These two houses then ruled England until 1485 (see **Lancaster; York**). Bryce Lyon

Plantain, *PLAN tuhn,* is the common name of a group of low-growing herbs, several of which are common weeds. The *common plantain,* also called the *broadleaf plantain,* is a species that often troubles gardeners. It may be recognized in spring by its circular cluster of broad light-green leaves that grow from the roots. Tall, slender spikes grow up from the center of the cluster. In the summer, these spikes are thickly covered with tiny green flowers. Other plantains include the *narrow-leaf plantain,* also known as *rib grass,* which has narrow leaves and short, thick spikes; and the *seaside plantain,* which has leaves that are used in medicine to lessen inflammation. The seeds of various types of plantains are used as a mild laxative.

WORLD BOOK illustration by Lorraine Epstein

Common plantain

A tropical plant called the plantain is a kind of banana. The fruit of this plant looks much like the banana, although it is hard and starchy and is eaten cooked. The plantain's fruit has become one of the chief foods in tropical countries. A type of flour is made from the fruit of the plantain. See **Banana**. Anton A. Reznicek

Scientific classification. Plantains belong to the plantain family, Plantaginaceae. The scientific name for the broad-leaf plantain is *Plantago major.* The narrow-leaf is *P. lanceolata.* The seaside plantain is *P. maritima.*

Plantation is a large land area where workers usually grow a single crop. The most common crops that are grown on plantations are cocoa, coffee, rice, rubber, sugar cane, bananas, pineapple, and other kinds of tropical fruit. Most plantations are located in rich, level land areas in the tropical and subtropical regions of the world.

Plantations vary widely, depending largely upon their stage in development. Three separate types of plantations may be characterized as those that use slave labor, "free" labor, and skilled labor.

Slave-labor plantations were established by western Europeans in the colonies they established throughout the world. The Europeans furnished money and management for plantation development and also the market for what was produced. Most of the plantation workers were slaves or *indentured servants* who were bound by contract to serve a landowner. They usually worked long hours in large gangs. They received few of the comforts of life. Plantation owners were the ruling class in society. These landowners operated the plantations with slave labor in various parts of America from the colonial period until slavery was abolished in 1865. After that date, plantations operated with the use of free labor.

"Free"-labor plantations came into use when slavery fell into disrepute. These large farming units produced single crops and paid low wages to hired hands. Laborers who worked for wages and *sharecroppers* (farmers who worked for a share of the crop) did most of the work. Various degrees of semislavery developed, including *peonage.* Peons are forced to work to pay off debts. Sharecroppers received a share of the crop from

tl land on which they normally did all the work. Wage l:orers worked in gangs and received wages. Wage la-b·ers, peons, and sharecroppers frequently had an o:n account at the plantation *commissary* (supply s re). The commissary often charged high prices. As a r ult, the workers would become indebted to the c ner and would be forced to work off their debts. S:h plantations still exist in parts of the world, and the p ople who own them form the ruling class.

Skilled-labor plantations are now developing in r ny areas. Sharecroppers and wage hands are disap-p aring. Since World War II (1939-1945), plantation agri-c ture has changed rapidly. Machines and skilled work-e are now being used instead of mule power and h d labor. Laborers receive higher wages and live bet-t than plantation workers did in earlier days. Planta-t ns no longer use gangs of slaves or peons. A more mocratic society has replaced the rule by plantation ners. In many areas, plantations are being broken up, d the land is being distributed among the former ntation workers. James D. Arnold

asma, *PLAZ muh,* is the liquid portion of blood. This llowish, transparent fluid makes up more than half the lume of blood in the human body. The solid parts of ood—the red and white blood cells and the platelets—e suspended in the plasma. Plasma consists of more an 90 percent water. A variety of dissolved substances, cluding proteins, salts, digested foods, and wastes, ake up the rest of the plasma.

Functions of plasma. Plasma makes the blood fluid. ithout this characteristic, blood could not perform its b of transporting vital substances throughout the dy. Plasma carries blood cells and platelets to all parts the body. It also transports digested foods to the dy tissues. It picks up soluble waste materials from e tissues and carries them to the kidneys for excretion om the body. Plasma also transports hormones that lp control the function and development of many rts of the body.

The three major types of plasma proteins—*albumin, obulins,* and *fibrinogen*—each serve important func-

CNRI, Science Photo Library

he plasma protein fibrinogen promotes clotting. When a ood vessel is injured, fibrinogen forms sticky threads, *above,* hich hold cells together to prevent excessive blood loss.

Art Glauberman, Photo Researchers

Plasma is separated from whole blood by rotating bags of blood in a centrifuge. Then a laboratory technician, *above,* filters and separates the yellow plasma from the red blood.

tions. Albumin helps maintain a balance between the amount of fluid that leaves and enters the blood vessels. If plasma does not have enough albumin, excessive fluid passes through the blood vessels and accumulates in the tissues, causing the body to swell. In addition, albumin binds and carries nutrients absorbed from the digestive system.

The globulins—particularly the *gamma globulins*—help protect the body from disease. Gamma globulins are *antibodies,* disease-fighting proteins that attack bacteria, viruses, poisons, and other harmful substances (see **Immune system**).

Fibrinogen is the most abundant of a group of plasma proteins called *clotting factors.* These proteins prevent excessive loss of blood from injured vessels. When a person starts bleeding, a chain reaction involving the clotting factors takes place. This reaction results in the formation of a blood clot.

Uses in medicine. Physicians use plasma for transfusions to provide clotting factors and other proteins. Plasma transfusions are used chiefly in the treatment of bleeding disorders. Because it contains most of the clotting factors, a transfusion of plasma can halt bleeding in many such cases. Plasma transfusions are also used to treat severe blood loss when whole blood is unavailable. Such transfusions have saved the lives of millions of soldiers injured in battle.

Blood banks obtain proteins from plasma through a process called *fractionation.* Proteins obtained in this way include gamma globulins and individual clotting factors. Doctors sometimes use gamma globulins to protect against or modify such infectious diseases as measles and viral hepatitis. They use an individual clotting factor to control *hemophilia,* a bleeding disorder caused by inherited deficiency or abnormality of a certain clotting factor.

Blood banks separate plasma from whole blood by allowing the solid components to settle by gravity or by using a machine called a *centrifuge.* A special donation

technique called *plasmapheresis* removes only plasma, returning the blood cells and platelets to the donor. Blood banks freeze plasma intended for use in transfusions. Plasma intended for fractionation is sent to various companies for processing. G. David Roodman

Plasma, *PLAZ muh,* in physics, is a form of matter composed of electrically charged atomic particles. The sun and the other stars, and most of the other objects in space, consist of plasma. Lightning bolts also consist of plasma, but few other plasmas occur naturally on the earth.

Artificially created plasmas have many practical uses. For example, electricity turns the gas in the tube of a neon sign into a plasma that gives off light. A welding process called *arc welding* uses electricity to produce the high temperatures needed to join pieces of metal. Electric rockets may someday use plasma fuels for long trips through space.

A plasma can be made by heating a gas or by passing an electric current through it. A gas consists of atoms or molecules. Each atom has a nucleus surrounded by one or more negatively charged particles called electrons. Great heat or a flow of electricity *ionizes* an atom by stripping off one or more of its electrons. These electrons then move around independently. An atom or molecule that loses electrons has a positive charge and is called an *ion.* As the temperature increases, more and more atoms in a plasma become ionized.

The physical and electrical qualities of a gas change greatly when it becomes a plasma because the ions and electrons in the plasma are separated. For example, most gases conduct electricity poorly and are not affected by magnetic fields. A plasma, on the other hand, conducts electricity well and is affected by magnetic fields. Gases consist of atoms that move around independently and in no definite way. The electrons and ions in a plasma may move around in groups, usually in wavelike motions. Plasmas have qualities unlike those of the three basic forms of matter—gases, liquids, and solids. For this reason, physicists consider plasma a fourth state of matter.

Scientists hope someday to generate electricity by using plasmas to control the process of *nuclear fusion.* Nuclear fusion gives off tremendous amounts of energy when two lightweight atomic nuclei unite to form a heavier nucleus. The energy from controlled fusion could be used as heat to make steam for electric generators. But temperatures of up to 100,000,000° C are required to make the atomic nuclei react. Such a high temperature would melt any container. Many physicists are attempting to produce controlled fusion with hot plasmas held in place by strong magnetic fields or by some other method that does not involve use of a material container. Francis T. Cole

Plaster is a mortar coating that is applied to wall surfaces and ceilings of buildings to make them more airtight and to provide a finished surface. Plastering is putting the plaster on these walls. Certain types of plaster are called *stucco.* Stucco is often used on the outer walls of houses.

Plaster is commonly made of sand and a cementing agent, such as gypsum, lime, or portland cement. The ingredients are mixed with water. Hair or fiber is mixed with the first and second coats to strengthen the plaster. The hair is goat or cattle hair, and the fiber is Manila, jute, or wood fiber.

Lightweight materials such as *perlite* or *vermiculite* may be used instead of sand. These materials absorb sound and are fire resistant.

Plaster bases. Plaster can be put directly on a masonry wall, but it cannot be put directly on a solid wood wall. The surfaces to which plaster can be applied are called plaster bases. Bases may be of various kinds of building blocks, or brick or stone. Bases may also be made with *laths.* Laths are metal sheets, pieces of gypsum or fiberboard, or wooden strips that are put on the surface to be plastered to provide a better grip.

Wood laths are laid parallel, with narrow spaces between them. The plaster enters the spaces and forms wedges, called *keys.* The wedges hold the plaster to the laths. In most modern buildings, gypsum board or metal laths are used. Metal laths are metal sheets about 2 feet (0.6 meter) wide and 8 feet (2.4 meters) long. Open spaces in the sheets allow plaster to penetrate and obtain a firm grip. Gypsum board has a gypsum plaster core between surfaces of heavy paper. The paper and core are pressed together to form a plastering surface.

Plastering. The plaster is put on the plaster base with a special tool called a *trowel.* It is smoothed with a tool called a *darby* and may be made more even with a long straightedge called a *rod.* Wood or metal strips, called *grounds,* are placed around openings and along the top of the baseboard as guides for finishing the plastering. If the plastered wall is large, plaster guides called *screeds* are made on the *scratch* (first) coat. Three coats of plaster should be used on wood or metal lath. But only two coats are needed on a brick or tile surface.

aster of Paris is a white powder that, when mixed th water to form a paste, will turn hard in a few min-es. This substance is used for casting small statues, for aking models and molds, for surgical casts, and for her purposes. It is made by heating gypsum, a mineral ›mposed of calcium sulfate and water. When the water partly driven off, the gypsum softens and is easily ushed to form a powder. When water is added again, e mass hardens to a stonelike substance.

James S. Reed

lastic explosive is a puttylike explosive that can be olded into any shape. Plastic explosive is made of a *asticizer* (a substance that makes the explosive flexible) ıd either a mixture of two explosive substances called *›X* and *PETN* or RDX alone. Only a powerful *detonator* capsule containing an easily explodable charge) can ›t off a plastic explosive.

The United States Army developed plastic explosives ıring World War II (1939-1945). The explosives became mous in the early 1960's when a French terrorist ›oup, the Secret Army Organization (OAS), used them try to prevent Algeria from becoming independent. astic explosives have remained a popular weapon nong terrorists because they are powerful, easily hid-›n, and difficult to detect. Frances M. Lussier

See also **Explosive** (High explosives).

lastic surgery is a field of medicine that specializes in the repair or reshaping of defects of the body. It also may involve the repair of muscles, bones, blood vessels, and nerves. The word *plastic* comes from a Greek word meaning *to shape* or *mold.* Plastic surgeons shape and mold body tissues. They rearrange, remove, or replace tissue to restore normal function to deformed or damaged body parts. Plastic surgeons also attempt to improve the appearance of aging tissue or of unattractive body parts.

Methods of plastic surgery include *grafting* (transferring tissue), repairing or reshaping tissue structures, removing tissue, and, less frequently, replacing tissue with an artificial substance. In grafting, a plastic surgeon replaces damaged tissue with healthy tissue from another area of the body. The surgeon may graft a single tissue—such as skin, a nerve, or bone—or a combination of tissues. In some cases, the surgeon must reconnect the transferred tissue to the circulatory system. Otherwise, blood will not circulate through the tissue adequately and the tissue will die. Grafting is used in treating such cases as severe burns, gunshot wounds, and injuries resulting from automobile accidents.

Injuries or diseases involving the loss of tissue or of a body part require the rebuilding or reshaping of tissue structures. Under the appropriate circumstances, plastic surgeons may be able to reattach a severed body part. Often, however, the severed part is too severely damaged or has been without blood circulation for too long to permit repair. Congenital deformities, such as cleft lip, cleft palate, and birth defects of the face, ears, hands, and genitals, can be corrected by rebuilding and reshaping tissues. Similarly, a deformed or unattractive nose can be reconstructed and reshaped by a plastic surgeon in an operation called a *rhinoplasty.*

Some plastic surgery done for cosmetic reasons involves the removal of tissue. A facelift operation, also known as a *rhytidectomy,* gives the patient a more youthful appearance by removing excess or aged facial skin. Plastic surgeons use a technique called *liposuction* to remove excess fat from such areas as hips, thighs, and ankles. In this procedure, an incision is made in the skin and then fat is suctioned out through a tube.

Plastic surgeons can reconstruct or alter the size or shape of a woman's breasts. This type of operation is called a *mammoplasty.* In a mammoplasty, the surgeon inserts a synthetic implant into one or both breasts.

Qualifications for a plastic surgeon include a longer *residency* (period of training) than that of some other medical specialists. In the United States, plastic surgeons are certified by the American Board of Plastic Surgery. To be eligible for certification, a person must graduate from an accredited medical school and then serve at least three years of residency in general surgery and an additional two years of residency in plastic surgery. The person then must pass a written and oral examination prepared by the board.

A plastic surgeon's credentials can be verified by checking with a local medical society or with the American Board of Plastic Surgery in Philadelphia. Names of local plastic surgeons can be obtained from the American Society of Plastic and Reconstructive Surgeons Executive Office in Arlington Heights, Ill.

Strong, lightweight plastics make up the body of this van.

Amoco Chemical Company

Durable polyester fabrics are made of plastic fibers.

WORLD BOOK photo by Ralph J. Brunke

Plastics are used to package a variety of items.

Plastics have special properties that allow them to be used in a wide variety of products. The photographs above illustrate some of the many uses of plastics.

Plastics

Plastics are man-made materials that can be shaped into almost any form. They are one of the most useful materials ever created. Our homes, schools, and businesses are filled with plastic products. Engineers have developed plastics that are as rigid as steel or as soft as cotton. They can make plastics that are any color of the rainbow—or as clear and colorless as crystal. Plastics can be rubbery or rigid, and they can be shaped into an endless variety of objects, ranging from automobile fenders to squeezable bottles to soft fabrics. Plastic products, especially those used by industries, often have a useful life of many years.

Plastics consist of long chains of molecules called *polymers.* These chains are made of repeating patterns of smaller molecules. Each of the smaller molecules forms a "link" in the polymer's chain. In some plastics, the chains are rigid and are lined up like logs flowing down a river. In others, they are flexible and tangled like spaghetti on a plate. These different structures give plastics their most notable characteristic, the ability to be shaped. In fact, the word *plastics* comes from the Greek word *plastikos,* which means *able to be shaped.*

As useful as they are, plastics do have drawbacks. The biggest problem is that most plastics take a very long time to *decompose* (break down into simple compounds). Figuring out how to dispose of plastic wastes has become a major environmental concern.

The contributors of this article are all members of the staff of the Polymer Processing Institute (PPI) at Stevens Institute of Technology. They are Joseph A. Biesenberger, President of PPI and Professor of Chemical Engineering; Paul G. Kelleher, Associate Manager of PPI's New Jersey Polymer Extension Center; and Marino Xanthos, Research Director of PPI and Research Professor of Chemical Engineering.

How plastics are used

Engineers have created hundreds of different plastics, each with its own properties. They have developed plastics that can replace metals, natural fibers, paper, wood and stone, and glass and ceramics. Manufacturers use these plastics to make products stronger, lighter, longer lasting, easier to maintain, or less expensive to make. In addition, inventors have used plastics to create items that could be made with no other materials.

To replace metals. Plastics are used to replace met- in a variety of products. Automakers commonly use astic bumpers, fenders, and wheel covers in their oducts. In some cars, the entire body is made of plas- s. Plastic auto parts do not rust, nor do they dent as sily as metal ones. Plastic auto parts are easier and of- n less expensive to repair. Replacing metal parts with astic ones also reduces the weight of a vehicle, result- g in more efficient fuel use. Airplane manufacturers e plastic wing and body assemblies for many of these me reasons. These large, seamless parts also create s wind resistance than do riveted metal sections.

Plastics have also replaced metals in many building nstruction materials, such as pipe and home siding. astic siding does not dent as easily as that made from uminum. Pipe made from plastics is lightweight and sy to cut and join. Moreover, it does not corrode like etal pipe.

Surgeons mend broken bones with plastic parts her than metal ones, because the plastics are less ely to trigger a harmful reaction. Dentists often use astic fillings because—unlike metal fillings—the plastic es can match the patient's tooth color.

To replace natural fibers and hides. The textile in- stry uses plastics to replace such natural fibers as cot- n, ramie, silk, and wool. Plastic fibers may have such alities as strength, durability, and resistance to stains d wrinkling. Some plastic fibers are tough enough to used for automobile safety belts or bulletproof vests. hers are delicate enough to be made into sheer siery. Durability and resistance to stains and attack by oths make plastic fibers an excellent material for cloth- g, carpeting, and furniture coverings. Manufacturers n also treat plastic fibers to make them more difficult burn. Plastic fibers are often mixed with natural fibers produce fabrics with qualities similar to an all-natural bric but with added durability.

Plastics are also used to create synthetic leathers, edes, and furs. Spun plastic fibers replace down or athers in insulated jackets and pillows.

To replace paper. Plastics have replaced paper in any packaging applications. Plastic-foam packing ma- rials provide more protection for boxed products than ushed paper does. Many products, particularly deli- te electronic equipment, are packed in foamed plastic serts that fit the shape of the item exactly. Such hard- are items as nuts and bolts are packaged in clear plas- boxes that enable a buyer to see the product.

Plastic wraps have many uses. They preserve foods nger than paper wraps can. Plastic wrap can stretch to rm a seal around the opening of a container. Many ms sold in stores, including board games and com- ct discs, are sealed in clear plastic wrap.

To replace wood and stone. Plastics have replaced ood and stone in many applications. Laminated plastic untertops come in a variety of patterns. Some look e marble. Laminated countertops are lighter, less ex- nsive, and easier to install than marble ones. They so resist marring and stains.

Furniture makers use plastics to produce cabinet ors and tabletops that look like wood but are easier clean and do not warp. Plastics have also replaced ood in boat hulls. Plastic boats are stronger than ooden ones and require less maintenance. Unlike wooden hulls, plastic hulls can be constructed easily in one piece. These smooth, one-piece hulls can be shaped to cut through water with less resistance.

To replace glass and ceramics. Because they are lighter and much less likely to break, plastics have replaced glass or ceramics in a variety of products. Plastic wall tiles, bathtubs, and sinks are cheaper and easier to install than ceramic ones. Airplane windows made of acrylic plastics are lighter and less brittle than glass. Safety and comfort have made lightweight, shatterproof plastic eyeglass lenses a popular substitute for glass lenses. Plastic bottles are also shatterproof, and they have replaced glass ones in packaging such products as milk, ketchup, household cleaners, and many other goods. Plastic bottles also weigh much less than glass ones and so help reduce shipping costs.

To provide new characteristics. Plastics are used in many ways that would not be possible for other materials. They have many medical applications because they are not harmful to the body and can be formed into any shape. Parts made from plastics can replace damaged hip, knee, and finger joints. Plastic pieces are used to rebuild facial structures damaged by accidents. Sometimes, plastic parts are used to replace faulty heart valves and damaged arteries.

Plastics are also used to make insulating foam that blocks the flow of heat and sound. The foam can be blown into the walls of a home through a small hole. Integrated circuits, which hold thousands of transistors that control the flow of electric current, are sealed in plastics. The plastics protect the delicate transistors without interrupting the flow of electric current.

Types of plastics

Although there are hundreds of different plastics, all of them belong to one of two basic types, based on how they behave when heated. These types are (1) thermosetting plastics and (2) thermoplastics.

Thermosetting plastics—or thermosets, for short—can be heated and set only once. They cannot be remelted or reshaped. When a thermoset is heated, it undergoes a chemical reaction called *cross-linking,* which binds its polymer chains together. This reaction is similar to the hardening of an egg when it is boiled. Once it has hardened, it cannot become a liquid again. Because thermosets cannot be remelted, engineers use them in applications that require high resistance to heat. Products made from thermosetting plastics include pot handles, trays for sterilizing medical instruments, and parts for airplanes and spacecraft.

Thermoplastics can be melted and re-formed again and again. Their polymer chains do not form cross-links. Thus, the chains can move freely each time the plastics material is heated.

Thermoplastics are used much more widely than are thermosets. Manufacturers prefer thermoplastics because they are easier to handle. They also require less time to set—as little as 10 seconds, compared to as long as 5 minutes for thermosets. And unlike thermosets, most thermoplastics can be dispersed in liquids to produce durable, high-gloss paints and lacquers. Because their molecules can slide slowly past one another, some thermoplastics tend to lose their shape when exposed to constant pressure over a long period of time. For this

Kinds of plastics

All plastics are classified as *thermosetting* or *thermoplastic,* depending on the way they act when heated. This table lists some common thermosetting and thermoplastic materials according to their chemical names. Each kind includes hundreds of compounds formed by adding chemicals to the basic material.

Thermosetting materials
Allylic: strong, resists heat and weather. Used for electronics parts, coatings for moisture protection.
Epoxy: resists water and weather, hardens quickly, has high bonding strength. Used for adhesives, casting compounds, reinforced plastics, protective coatings, tools.
Melamine- and urea-formaldehyde: easily colored, resists heat, odorless, tasteless. Used for dinnerware, lampshades, adhesives, buttons, tabletops, electrical parts, plywood binders.
Phenolic: resists heat and cold. Used for adhesives, appliance handles, electrical devices, surface coatings.
Polyurethane: tough, resists chemicals. Used for electrical insulation, structural parts, insulation foam, foam seat cushions, fabrics with elastic qualities.
Silicone: resists weather, has high elasticity and good electrical qualities. Used for oven gaskets, electrical insulation, greases and other lubricants, waterproof materials.
Unsaturated polyester: strong, hardens quickly, molds under low pressure. Used for automobile parts, boats, bowling balls.

Thermoplastic materials
ABS (acrylonitrile-butadiene-styrene): strong, long wearing, resists stains and chemicals. Used for telephones, automobile wheel covers, handles, appliance parts, luggage, piping.
Acetal: tough, stiff, keeps its shape under pressure, has high melting point. Used for refrigerator and washing machine parts, cams, wheels.
Acrylic: resists weather and chemicals, easily colored, has high clarity. Used for optical lenses, airplane canopies, signs, displays, automobile tail lights, fabrics, paints.
Cellulose acetate: tough, transparent. Used for toys, novelties, handles, packaging, photographic film, machine guards.
Cellulose acetate butyrate: tough, resists water. Used for steering wheels, pipe, tool handles, industrial parts.
Nylon: strong, springy, resists abrasion, has good electrical qualities. Used for fabrics, gears, bearings, hardware, brush bristles, electrical appliances, carpeting.
Polycarbonate (a polyester): resists heat, has high impact strength. Used for business machine parts, electrical connectors, coil forms, light diffusers, windows, eyeglass safety lenses, airplane canopies.
Polyethylene: lightweight, flexible, has waxlike feel. Used for bottles, packaging, electrical insulation.
Polyethylene terephthalate (a polyester): strong, flexible, resists water and chemicals. Used for magnetic tapes, plastic soft drink bottles, decorative films.
Polypropylene: lightweight, resists heat and chemicals. Used for rope, packaging, automobile parts, baby bottles, appliance parts, carpeting.
Polystyrene: lightweight, tasteless, odorless. Used for housewares, toys, electrical insulation, radio cabinets, packaging.
Polytetrafluoroethylene: resists heat and chemicals, slides easily. Used for cable insulation, bearings, valve seats, gaskets, frypan coatings, slides and cams.
Polyvinyl chloride: strong, easily colored, rigid or flexible, resists abrasion. Used for imitation leather, packaging, pipe, electrical insulation, flooring.
Polyvinylidene chloride: crystal clear, tough. Used for packages for meat and other foods.

reason, manufacturers prefer to use thermosets for such products as plastic seats on buses.

How plastics are made

The substances used to make plastic products are called *synthetic resins.* These resins are made primarily from petroleum, but some come from such other natural sources as coal, natural gas, cotton, and wood. Chemical manufacturers produce the resins and sell them to companies that make plastic products.

The chemistry of plastics. To understand how plastics are made, it is helpful to know something about the chemistry of polymers. The polymers in plastics are made up of small molecules called *monomers.* Most of these molecules are composed of carbon, hydrogen, nitrogen, and oxygen atoms. Some include chlorine, fluorine, silicon, or sulfur atoms. A polymer chain consists of hundreds, thousands, or even millions of monomer links. In some polymers, these links are made up of one kind of monomer, repeated over and over. In other polymers, the chains are composed of two or more kinds of monomers, which may be linked randomly or in alternating sequences. In some polymers, blocks of one kind of monomer are joined to blocks of another kind.

Polymer chains may or may not have branches. A chain may have branches on only one side or alternating from one side to the other. The chains may pack together in straight rows to make a stiff, crystalline solid. Or they may remain tangled and spread out, to make a soft, rubbery material. The properties of plastics depend on the types of monomers in their polymer chains, the lengths of the chains, and the arrangement of the chains.

Different kinds of polymer molecules can be mixed together to form *polymeric alloys,* or *blends.* Alloys are often easier to create than new synthetic polymers. They may have properties that lie between those of their component polymers, or they may have properties that are better than either. Polymer scientists can engineer plastics blends with the ideal properties for nearly every task. Alloys are used in products that range from packaging films to automobile body parts.

Making synthetic resins. Resin manufacturers make polymers by combining chemical compounds. These range from familiar chemicals, such as ammonia and benzene, to compounds with tongue-twisting names, such as hexamethylenediamine. When a manufacturer combines appropriate compounds, chemical reactions cause atoms to cluster together to form monomers. Further reactions cause the monomers to *polymerize*—that is, to form long chains of molecules. Polymerization produces the synthetic resin.

The steps in polymer building can be illustrated by the production of polystyrene resin. To make polystyrene, a chemical manufacturer begins with the liquid benzene and the gas ethylene, two chemicals derived from petroleum. The manufacturer bubbles the ethylene through the benzene. During this process, the compounds react to form the liquid *ethylbenzene.* Ethylbenzene is used to make liquid styrene by heating ethylbenzene gas to a high temperature and bringing it into contact with certain metal oxides. This process removes some hydrogen atoms from the ethylbenzene. The remaining atoms form molecules of styrene.

Finally, the manufacturer polymerizes the styrene to make solid polystyrene. One way this can be done is by suspending the styrene in water, adding chemicals, and heating it. A chemical reaction causes the styrene molecules to link together and form chainlike molecules of polystyrene. The manufacturer then forms the solid

p ystyrene into grainlike particles. These particles are tl raw material used to mold polystyrene products.

Vlanufacturers frequently use *additives* to change the p operties of a plastics resin. Common additives include (reinforcements, (2) fillers, (3) plasticizers, and (4) pig-n nts.

Resin makers use such reinforcements as glass fibers c carbon fibers to give plastics extra strength or rigidi-t The resulting mix, called a *composite* or a *reinforced p stic,* may contain from 10 to as much as 80 percent re-i orcement. Composites are lightweight and can re-p ce metals in missiles, aircraft, and automobiles.

Resin manufacturers may use fillers to improve the c ality of plastics or to extend an expensive resin. Com-m n fillers include powdered wood, talc, and clay.

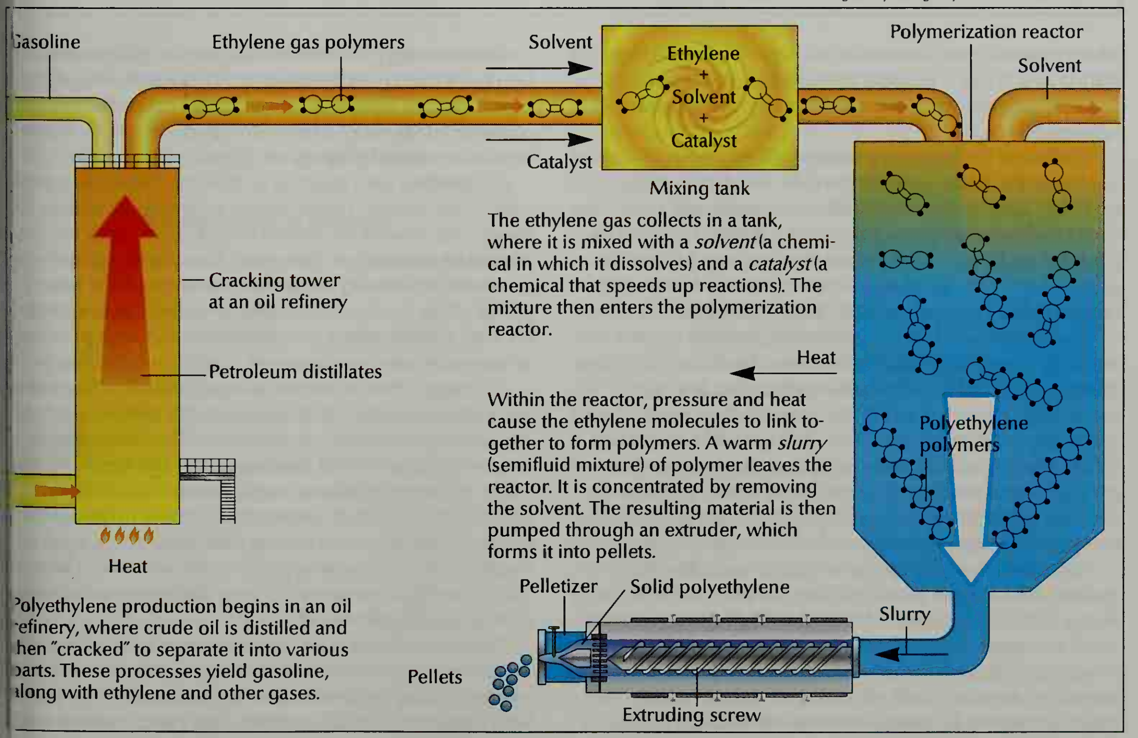
Vlanufacturers add plasticizers to certain synthetic r ins to make them softer, more flexible, and easier to s ape. Plasticizers overcome the attractive forces be-t een the polymer chains and separate them to prevent i ermeshing.

Pigments change the color of plastics. Resin makers u pigments to produce unlimited varieties of color.

Additives enable resin manufacturers to make plastics e en more useful. For example, vinyl plastics are natural-l clear and rigid. But thanks to additives, vinyl plastics c n be made into products ranging from rigid, gray p e to slightly flexible, black phonograph records to s t, transparent windows for convertible automobile t ps.

Making plastic products. Manufacturers use seven m in processes to shape plastics into products. These processes are (1) molding, (2) casting, (3) extrusion, (4) calendering, (5) laminating, (6) foaming, and (7) thermo-forming.

Molding. There are a variety of molding processes, including compression, injection, blow, and rotational molding. In all these processes, force is applied to the plastic material during and after it enters the mold. Once the product has hardened, it is released from the mold.



Compression molding is the most common method of molding thermosetting plastics. Compression-molded products include automobile hoods and fenders, electrical switches, and handles for cooking utensils and irons. In compression molding, resin powder is put into a mold. The manufacturer then heats the mold and, at the same time, applies pressure. After the plastics have set, the mold is opened and the product is released. The mold can then be refilled.

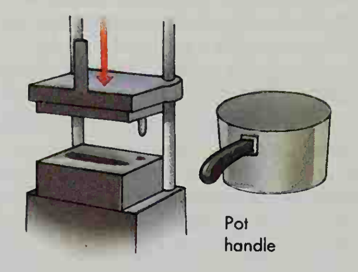
Injection molding is the most widely used method of molding thermoplastics. Injection-molded products include telephones, computer housings, automobile steering wheels, and a variety of other items. In injection molding, resin pellets fall from a hopper into a heated, horizontal barrel, where they melt. A plunger or revolving screw inside the barrel pushes the liquid resin under pressure into a mold. Most injection-molded products take only 10 to 30 seconds to harden. The mold is opened, and ejector pins push the formed product out of the mold. The mold is then closed and refilled.

Blow molding is used to make bottles and other hollow objects. In this process, a tube of molten resin, called a *parison,* is inserted into a mold. Compressed

lw plastic resins e made Plastic resins are made primarily from chemicals that come from petroleum. This diagram shows how ethylene, a gas derived from petroleum, is polymerized to form polyethylene plastic resins.

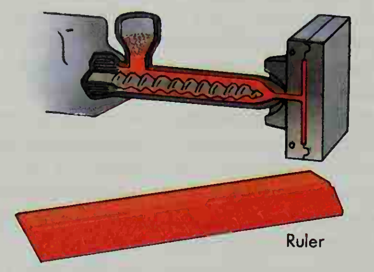
WORLD BOOK diagram by George Fryer, Bernard Thornton Artists

Polyethylene production begins in an oil refinery, where crude oil is distilled and then "cracked" to separate it into various parts. These processes yield gasoline, along with ethylene and other gases.



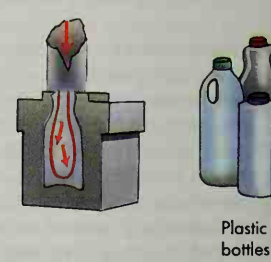
The ethylene gas collects in a tank, where it is mixed with a *solvent* (a chemical in which it dissolves) and a *catalyst* (a chemical that speeds up reactions). The mixture then enters the polymerization reactor.

Within the reactor, pressure and heat cause the ethylene molecules to link together to form polymers. A warm *slurry* (semifluid mixture) of polymer leaves the reactor. It is concentrated by removing the solvent. The resulting material is then pumped through an extruder, which forms it into pellets.

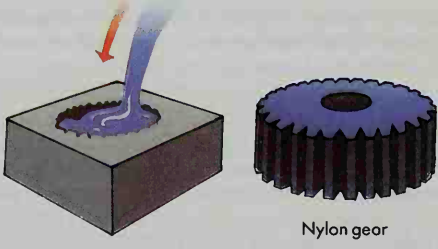


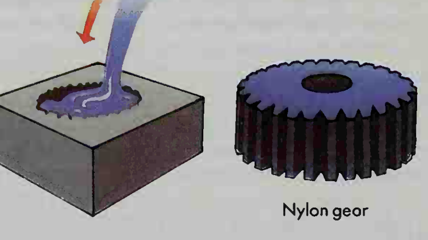
How plastic products are made

Manufacturers make plastic products from plastic resins, which melt into a syrupy liquid when heated. The products are shaped by several methods, as shown in these illustrations.

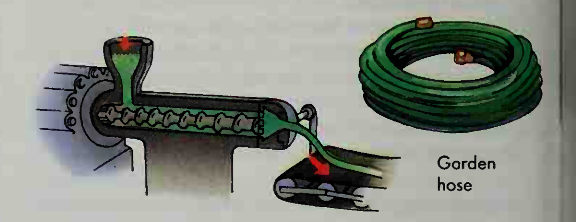


WORLD BOOK illustrations by Paul D. Turnb





Compression molding uses heat and pressure to shape plastics. The process is commonly used to mold thermosetting plastics.



Injection molding shoots molten plastic material under pressure into a mold. It is the most widely used method of molding thermoplastics.

Blow molding produces hollow objects. It uses air or steam to expand a tube of molten resin, forcin the material against a mold's walls.

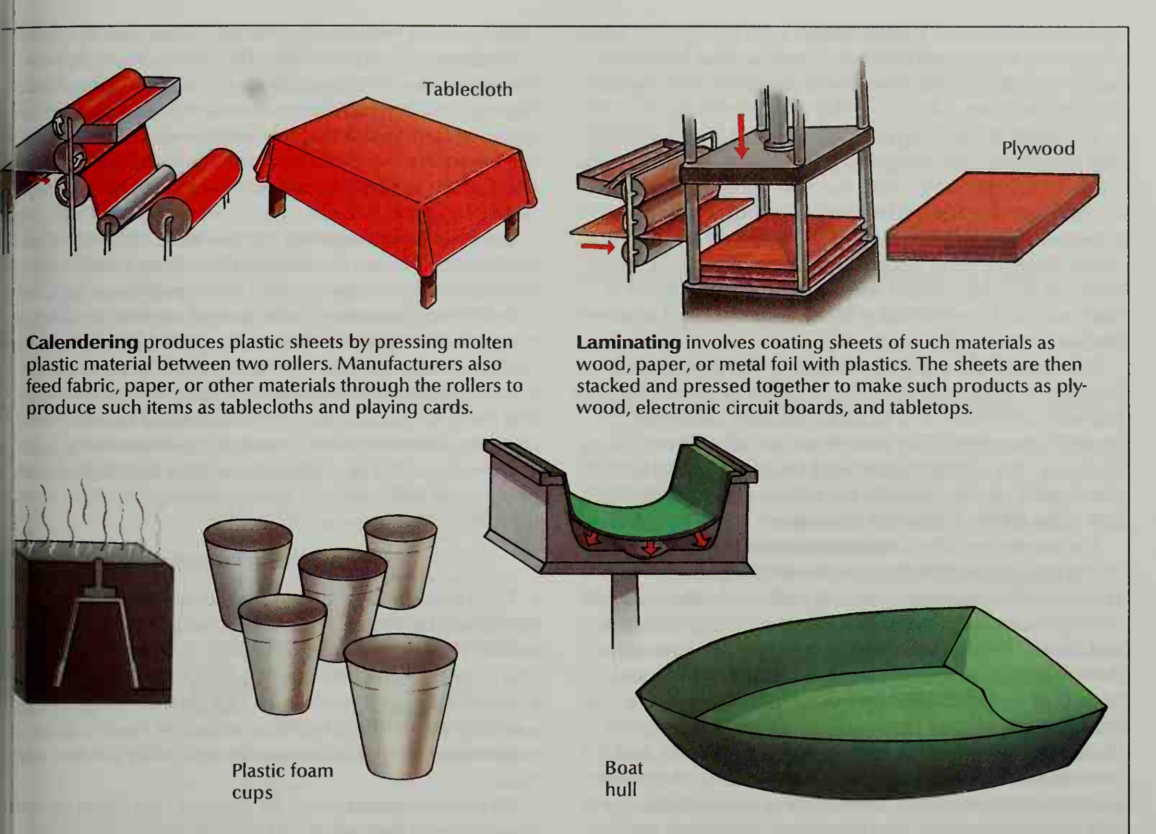
Casting does not depend on any external pressure to shape the plastics. In the casting process, melted resin is simply poured into a mold. Manufacturers use casting to produce thick, solid objects.

Extrusion is used to produce such continuous forms as pipe, rods, fibers, and wire coatings. Rotating screws force the plastics through a heated barrel, in which they melt, then force them out through a specially shaped die.

air or steam then is forced into the parison, which expands much like a balloon being inflated. This action forces the resin against the walls of the mold, where it is held until it hardens.

Rotational molding also forms hollow objects, such as soccer balls, dolls, and automobile fuel tanks. In this process, a mold is partly filled with powdered resin. The mold is then heated while a motor rotates it slowly. The powder melts as it tumbles inside, coating the mold's inner surface. After all the powder has melted, the still-rotating mold is cooled, and the object solidifies.

Casting, unlike molding, does not depend on any external pressure to shape the plastics. Manufacturers use this method to shape both thermoplastics and thermosetting plastics. To cast thermosets, they pour a liquid resin containing chemicals into a mold and harden it by applying heat. For thermoplastics, the molten resin is poured into a mold and cooled until it sets. Processors employ casting to make thick plastic panels and to produce gears, paperweights, and other solid objects.



Extrusion is used to produce pipe, rods, fibers, wire coatings, and other products that have the same shape along their entire length. Solid thermoplastics particles from a hopper enter a stationary, heated barrel. One or more rotating screws force the particles through the barrel, where they melt as they are pushed along. The molten material is forced out through a shaping die.

Calendering produces a continuous plastic sheet o film by pressing molten plastics between pairs of polished, heated rollers. Manufacturers feed fabric, pape or metal foil through the rollers to produce such item as plastic-coated playing cards and tablecloths.

Laminating uses plastics to bind together stacks of glass-fiber, wood, paper, cloth, or metal-foil sheets. Th sheets are coated or soaked with a resin. They are the placed one on top of the other. A machine squeezes t sheets together and heats them until the resin has joined them firmly. Laminating produces strong mater als with a wide range of thicknesses for such products as plywood, electronic circuit boards, and tabletops.

Foaming refers to any of several methods that produce plastic foams. All these methods involve introdu ing a gas into heated plastic resins. The gas expands a creates bubbles in the cooling resin. The resulting ma rial is lightweight plastic foam, which is sometimes called *cellular plastic.* Depending on the resins and th method, plastic foams can be stiff and strong, such as those used in packaging and home insulation. Others can be soft and rubbery, such as the foams in furnitur cushions and pillows.

Thermoforming is an inexpensive process used to mold items from sheets of plastics. In this process, workers clamp a plastic sheet over a mold. They then heat the sheet until it becomes soft. Next, a pump suc

Calendering produces plastic sheets by pressing molten plastic material between two rollers. Manufacturers also feed fabric, paper, or other materials through the rollers to produce such items as tablecloths and playing cards.

Laminating involves coating sheets of such materials as wood, paper, or metal foil with plastics. The sheets are then stacked and pressed together to make such products as plywood, electronic circuit boards, and tabletops.

Foaming is any of several methods that produce solid plastics filled with air spaces. To make plastic foam, for example, manufacturers use beads of thermoplastic resin containing a chemical that forms a gas when heated during molding.

Thermoforming is used to mold items from sheets of plastics. A sheet is clamped over a mold and heated until it becomes soft. A vacuum pump sucks air out through tiny holes in the mold, drawing the sheet into the mold.

r out through tiny holes in the mold. This creates a vac-
ım that pulls the soft plastic sheet down until it covers
ıe surface of the mold. There it cools and hardens in
e shape of the mold. Manufacturers use thermoform-
g to produce such objects as bathtubs, shower bases,
ıd yogurt containers.

Development of plastics

For thousands of years, people used natural gums
ıd resins with properties similar to plastics. For exam-
e, the ancient Greeks and Romans created decorative
ɔjects from *amber,* a fossil resin. During the Middle
ges, Europeans used the natural resin *lac,* and its puri-
ed form, *shellac,* to coat objects (see **Lac**).

By the mid-1800's, the commercial molding of plastics-
e natural substances had developed. Manufacturers
olded items from lac, *gutta-percha* (a tree resin), and
her substances obtained from animal, vegetable, and
ineral sources (see **Gutta-percha**). Products made from
ese natural "plastics" included brush handles, knobs,
ectrical insulation, phonograph records, and novelty
ems. Museums and collectors treasure the beautiful
olded objects created during the late 1800's and early
00's.

Despite their beauty, these natural molding materials
ıd several disadvantages. Manufacturers often had dif-
culty obtaining the raw materials. Some materials proved difficult to mold, and many of the finished products turned brittle and broke easily.

The invention of Celluloid. In the late 1860's, John W. Hyatt, a printer from Albany, New York, developed a material to replace the scarce ivory used to make billiard balls. In 1870, he and his brother Isaiah received a patent for the material, which they later named *Celluloid.* Celluloid was the first synthetic plastic material to receive wide commercial use.

Hyatt made Celluloid by first treating *cellulose,* a substance found in cotton, with nitric acid. He then combined the resulting substance, *pyroxylin,* with the solvent *camphor.* The end product, Celluloid, was a hard, stiff material that could be shaped under heat and pressure to form useful items.

Celluloid was used for years to make such products as combs, dentures, and photographic films. However, the material proved to be highly flammable. During the early 1900's, researchers produced a similar, but less flammable, material called *cellulose acetate.* Today, manufacturers use cellulose acetate to make films, fibers, and molded objects. Celluloid itself is still used to make ping-pong balls.

The invention of Bakelite. During the early 1900's, Leo Baekeland, a chemist from New York City, attempted to make a synthetic shellac by combining the chemicals carbolic acid (also known as phenol) and formalde-

hyde. Chemists had experimented with combining these chemicals for several years. But the reaction had been too violent to contain. Baekeland succeeded in controlling the reaction, which created *phenolic resin.*

The resin did not turn out to be the synthetic shellac that Baekeland had sought. But his research was hardly a failure, for he had created the first completely synthetic resin and the first of the thermosetting plastics. He patented it in 1909 and named it *Bakelite,* after his own name. Bakelite soon became widely used to make such items as telephones and handles for pots and irons. It continues to be used today in the electrical and automotive industries.

Growth of the plastics industry. The introduction of Bakelite in 1909 gave scientists a better understanding of polymer chemistry. The plastics industry expanded steadily throughout the next three decades. Scientists in Germany, the United States, and the United Kingdom conducted a great deal of research in plastics, shedding new light on the materials' structures.

The most dramatic developments occurred in the 1920's and 1930's. Four important thermoplastics—acrylics, nylon, polystyrene, and polyvinyl chloride (PVC or vinyl)—came into commercial use. Acrylics are strong and clear. They became widely used for airplane windows. Nylon was used to make women's hosiery and, later, such molded products as bearings and gears. Manufacturers used polystyrene in many products, including clock and radio housings, toys, wall tile, and food containers. PVC, too, had numerous applications, and it found its way into such diverse products as garden hoses, raincoats, wire insulation, and electric plugs. The introduction of specialized machinery to form and mold plastics into useful items also helped the growth of the industry.

Important thermosetting plastics called *unsaturated polyesters* were introduced commercially in the 1940's. Important thermoplastics developed during the 1940's included polyethylene, silicones, and epoxy resins. All of these plastics found new uses during the early 1950's. Polyethylene proved an excellent material for dishes, squeezable bottles, plastic bags, artificial flowers, and other products. Manufacturers used silicones in lubricants and electrical insulation, and physicians used them in body implants. Epoxy resins gained wide use as strong adhesives. Manufacturers used unsaturated polyesters to make boat hulls. In 1953, the General Motors Corporation introduced the Chevrolet Corvette—a sports car with a body made of unsaturated polyester reinforced by glass fibers. The Corvette rolled into history as the first mass-produced automobile with a plastic body.

The uses of plastics continued to grow during the late 1950's and the 1960's. This growth corresponded directly to the growth of the petrochemical industry, which is the major producer of the raw materials for plastics. Engineers found new uses for plastics in medicine, nuclear and space research, industry, and architecture. Polymer chemists developed several new plastics that are especially resistant to chemicals and extreme heat.

Throughout the 1970's and 1980's, plastics continued to find new applications, appearing in such products as microwave cookware, personal computer housings, and compact discs. Aerospace engineers used heat-resistant polyurethane foam to cover the external fuel tanks of t United States space shuttles. This plastic foam acts as heat insulation to prevent loss of fuel by evaporation. During the late 1980's, scientists developed the first practical *conductive plastics,* which—unlike other plas tics—can carry an electric current. Conductive plastics have possible uses in batteries, wiring, and static-resistant fabrics.

Recent developments include the creation of ther moplastics that can be used to make items that must withstand high temperatures. These polymers include polysulfone, polyetherimide, polyphenylene sulfide, a polyetheretherketone. They can be used in medical de vices that must be heat-sterilized, electrical and electronic moldings for high-temperature environments, and parts for automobile engines. *Liquid-crystal polymers* are another type of modern plastics material. Su polymers consist of rodlike molecules that align durin processing and produce items with high strength in th direction of alignment.

The plastics industry

The United States, Japan, and other industrialized na tions lead the world in plastics production. The plastic industry continues to grow rapidly in these countries. The growth of the industry in any country depends on plentiful supply of petroleum.The plastics industry off a variety of job opportunities, including careers in research, design, machine operation, quality control, an sales.

Plastics companies may be divided into three gener groups: *resin manufacturers* (mostly chemical companies) who make and supply resins; *processors* who shape the resins into products; and *finishers and asse blers* who make products by cutting, drilling, decorating, and assembling plastic parts. Most resin manufacturers are in locations that allow easy access to suppli of petroleum. Most processors, finishers, and assemblers operate in areas where they can serve many indu tries.

Plastics and the environment

As more and more plastic packaging materials are used by consumers, more plastic waste is generated. Plastics do not readily break down, and so this waste contributes significantly to environmental pollution by occupying landfill space.

Recycling has emerged as one method of combatin the problem of plastics waste. Industries that produce use large amounts of plastics have recycled their wast for years. Usually they clean and separate the plastics b type. They recycle the thermoplastics by remelting and re-forming them into new products. Thermosets are ei ther ground into fine powders or shredded. The powders are used as fillers. The shreds can be used as insu lation in such products as quilted jackets and sleeping bags.

In the 1980's, many cities and towns turned to recycling to help dispose of consumer plastics waste. Thes communities require citizens to sort certain plastic items—such as polyester soft drink bottles and polyeth ylene milk bottles—from other waste materials. These plastics can be reused in the same manner as industri plastics waste.

Some communities do not separate the plastics but i,tead burn the mixed municipal waste. This process y:lds energy that can be used for electric power or l ating. It requires, however, sophisticated incinerators t it greatly decrease the acid gases produced by the l rning of PVC and other plastics.

Another approach to the disposal problem is to de- s n plastics that can be broken down by nature and t ne. In the 1970's, chemists introduced *biodegradable* p stics. These plastics break down as microorganisms nsume starches or cellulose that are used to separate t e polymer chains. Scientists also created *photode- adable* plastics that break down through long expo- re to sunlight. The polymers in these plastics are de- mposed by a chemical additive that breaks down nen exposed to sunlight.

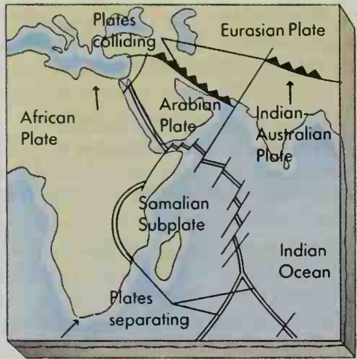
Plate tectonics is a theory that explains the origin of most of the major features of the earth's surface. For example, the theory tells us why most volcanoes occur where they do, why there are high ridges and deep trenches in the oceans, and how mountains form.

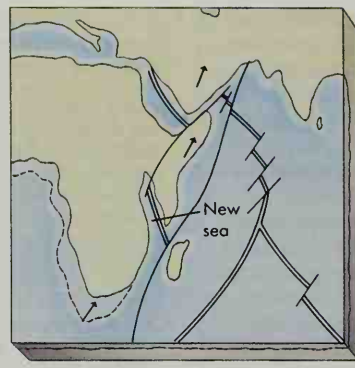
According to this theory, the earth has an outer shell made up of about 30 rigid pieces called *tectonic plates.* Some of these plates are gigantic. For instance, most of the Pacific Ocean covers a single plate.

The plates move about on a layer of rock that is so hot it flows, even though it remains solid. The plates are moving very slowly relative to one another. They move at speeds up to about 4 inches (10 centimeters) per year.

Plates have been moving about for hundreds of millions of years. So, in spite of their very low speeds, some of them have moved vast distances. In fact, over the past several hundred million years, plate movement has changed the map of the earth drastically. Earth scientists have determined that before about 200 million years ago, all the continents were part of a supercontinent called *Pangaea* (pronounced *pan JEE uh).*



Structure of tectonic plates



Tectonic plates are made up of the earth's *crust* and the outermost part of its *mantle.* The crust is the outermost layer of the earth. It is thin and rocky. All the dry land, all the ocean floors, and the beds of all the other bodies of water on earth are part of the crust. The man-

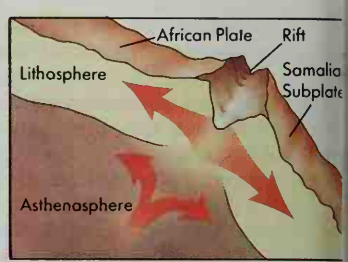
Earth's tectonic plates



The earth has a rigid outer shell broken up into large slabs of rock called *tectonic plates.* Many of these plates, shown here, include both ocean floor and dry land. Some plates have entire continents embedded in their tops. The plates move slowly about on molten rock underneath the shell. Arrows indicate the directions in which some of the largest plates move.

WORLD BOOK illustration by Charles Wellek

Plate movements are reshaping Africa. The African Plate, in which most of the continent is embedded, is moving north and northeast, *above left,* while the small Somalian Subplate is separating from the African Plate. If these movements continue for 50 million years, *above right,* a new sea will open up along the eastern coast of Africa.

WORLD BOOK illustration by Charles Wel

A rift has already formed in eastern Afr ca, where molten rock of the asthenosphere is rising, pushing apart tectonic plates of the lithosphere. In time, a sea will form along Africa's eastern coast.

tle is a thick layer of hot rock under the crust and above the *core,* a dense sphere at the earth's center. See **Earth** (illustration: Inside Earth).

The continents are embedded in the tops of plates, so as these plates move, they carry the continents along with them. The plates that carry continents do not have the same boundaries as their continents; they include both continents and ocean floor.

Plates are typically about 60 miles (100 kilometers) thick. But they may be less than 5 miles (8 kilometers) thick at certain places in the oceans and as much as 120 miles (200 kilometers) thick under parts of continents.

The plates as a whole make up the earth's *lithosphere.* The layer of mantle rock under the plates is the *asthenosphere* (pronounced *uhs THEEN uh sfihr*). This rock reaches temperatures between about 2400 and 3600 °F (1300 and 2000 °C).

Plate interactions

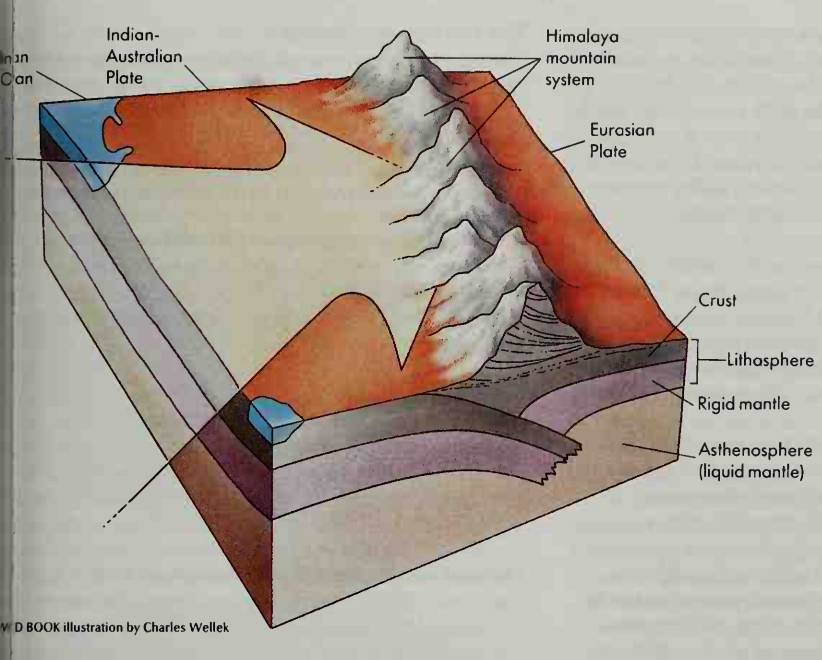
As the tectonic plates move about on the asthenosphere, they interact with one another at their boundaries. There are three types of boundaries: (1) *divergent,* where plates move apart from each other, (2) *convergent,* where plates move toward each other, and (3) *transform,* where plates slide alongside each other.

Divergent plate boundaries are mostly on ocean floors. There, the separation of plates, or *rifting,* creates lithosphere. Rifting on continents creates gaps into which water flows to form major river systems, lakes, and even oceans.

The rifting of the ocean floor enlarges the floor. *Magma* (liquefied rock) rises from the asthenosphere, filling the gap between the separating plates. The magma hardens, creating equal amounts of new crust on the edges of the two plates. The process of separation of plates and formation of new crust is called *sea-floor spreading.* This process creates about 1 square mile (2.4 square kilometers) of ocean crust a year.

The build-up of ocean crust on plate boundaries generates long underwater mountain ranges called *ocean ridges.* Some of these mountain ranges occur along the center of ocean basins and are called *mid-ocean ridges.* One such mid-ocean ridge, called the *Mid-Atlantic Ridge,* extends from waters east of the Canadian island of Newfoundland to an area off the southern tip of South America. See **Ocean** (map: The land beneath the oceans).

Earthquakes occur at ocean ridges when one plate edge drops down and grinds against the edge of a neighboring plate. These earthquakes occur a short dis tance beneath the surface of the plates, indicating that newly formed plate edges are very thin. See **Earthquak** (Mid-ocean spreading ridges).



The rifting of continents creates new seas as ocean waters fill a gap in continental crust. The Red Sea region, for example, is in an advanced stage of rifting. Th rift is already flooded by ocean waters—the Red Sea, a extension of the Indian Ocean.

The East African Rift, a unit of the Great Rift Valley th extends from Eritrea to Mozambique and connects to the Red Sea, is in an early stage of rifting. There, the ga is not yet deep enough to become filled with ocean wa ter from the Indian Ocean. However, scientists believe that in 50 million years an extension of that ocean may cut into southeastern Africa.

Convergent plate boundaries are places where lithosphere created at divergent boundaries is destroyed by recycling into the mantle. At a convergent boundary, the edge of a plate sinks, thrusting under th margin of its neighboring plate. This process is called *subduction.* The sinking plate can create deep ocean trenches where it plunges into the asthenosphere. Because the earth is not changing in size, scientists believ that *subduction zones* consume the same amount of ocean crust as ocean ridges create.

The subducting plates generate powerful earthquak and usually create a line of volcanoes along the overric ing plate boundary. A volcano forms when magma, hot gases, and fragments of rock burst through the surface Subduction zones generate magma at a depth of about 75 miles (120 kilometers) by melting three kinds of mate rial: oceanic crust at the top of the descending plate, ocean sediment dragged to great depths, and asthenosphere caught in the corner between the converging plates.

At some convergent plate margins, the overriding plate scrapes a thick mass of sediment off the descend ing plate. This process of *subduction accretion* (pro-

ransform plate boundaries, where plates slide izontally against each other, neither create nor de- y lithosphere. However, at these boundaries, or *sform faults,* powerful earthquakes can occur. For nple, devastating earthquakes have occurred in Cali- ia along parts of a transform plate boundary known ne San Andreas Fault.

he San Andreas Fault forms part of the boundary be- en two large plates—the North American Plate and Pacific Plate. The fault connects a spreading ridge in Gulf of California to a trench off the coast of north- California. The parts west of the fault are attached to Pacific Plate and are moving northwest. See **San An- as Fault.**

Plate movement

ate. Earth scientists measure the speed of plate ement by monitoring how rapidly a plate moves relative to the plate next to it. Today, plates move about 4 inches (10 centimeters) a year—about as rapidly as human hair grows. In the past, plates may have moved as fast as $6\frac{1}{4}$ inches (16 centimeters) per year.

The overall pattern of movement of the tectonic plates is a widening of the Atlantic Ocean and a shrinkage of the Pacific Ocean. The Atlantic is widening because sea-floor spreading at the Mid-Atlantic Ridge continues to create lithosphere. The Pacific is shrinking because much of it is ringed by convergent plate boundaries that are consuming its lithosphere.

Scientists have traced the movements of tectonic plates millions of years into the past. According to the commonly accepted description of plate movement, all the continents once formed part of an enormous single land mass called Pangaea. This mass was surrounded by a giant ocean known as *Panthalassa.*

About 200 million years ago, Pangaea began to break up into two large masses called *Gondwanaland* and *Laurasia.* These masses, in turn, broke up into the continents, which drifted to their present locations.

Evidence of plate movement. Earth scientists find much evidence of plate movement at the boundaries of plates. They study surface features, such as mountains and ocean trenches, and investigate the frequencies and locations of earthquakes and volcanic eruptions.

Volcanoes that rise within plates are also evidence of plate movement. Scientists believe that these volcanoes are caused by *mantle plumes,* columns of very hot mantle that rise from deep inside the earth to the base of the lithosphere. These plumes generate magma that rises through the lithosphere and erupts in places called *hot spots.*

As a plate moves over a hot spot, the spot can generate a chain of volcanoes. For example, a hot spot under the Pacific Plate generated volcanoes that became the Hawaiian islands.

Paleomagnetism (the study of magnetism in ancient rocks) also provides evidence of plate movement. The

evidence is in rocks that contain magnetic particles.

When such a rock was hot and liquid, the magnetic particles moved too rapidly to be influenced by the earth's magnetic field. But as the rock cooled and solidified, the particles aligned themselves with the earth's magnetic field, like tiny compass needles. Thus, the particles continue to point in the direction of the magnetic field that was present during the time that the rock cooled.

So when the plate containing the rock either drifts to a different latitude or rotates, the particles no longer align with the earth's magnetic field. A comparison of the direction in which the particles now point in the rock with the direction of the earth's present magnetic field provides information about where the plate was when the rock solidified.

Causes of plate movement. Tectonic plates slide mostly because of temperature changes and gravity. As an edge that has formed on the ocean floor cools, it shrinks, becoming denser. After about 25 million years of cooling and shrinking, the edge becomes so dense that gravity can pull it down into the asthenosphere. There, the intense heat and increased pressure due to the great depth change the crust of the sunken plate edge into even denser rock. Because of the additional density, gravity pulls the plate edge into the asthenosphere even more strongly.

This sinking action is known as *slab-pull* because the sinking edge pulls the remainder of the slablike plate behind it. Many scientists believe that slab-pull is the main action driving the motion of plates with sinking edges.

Gravity also causes plates to slide downhill away from ocean ridges. This sliding force is called *ridge-push.*

Another cause of plate movement is the simple pushing of plates against one another. Scientists believe that large plates shove some small plates about.

The rise of mantle plumes and other movements of mantle rock may also affect the motion of tectonic plates slightly. The circulation of mantle rock as it rises to the top of the asthenosphere, cools, and then sinks is known as a *convection current.*

Earth scientists once thought that convection currents caused continental drift. Today, however, most earth scientists believe that such currents are primarily a result of the sinking of plates, rather than the cause of plate motion.

Maintaining tectonic activity. The interior of the earth has generated enough heat energy to keep the planet tectonically active since it formed at least 4.5 billion years ago. This energy has maintained tectonic activity by keeping the asthenosphere so soft that the lithosphere can sink into it.

The interior of the earth generates heat energy mainly through the radioactive decay of atoms in the crust and mantle. In radioactive decay, radioactive atoms release energetic particles and rays. Material near these atoms absorbs energy from the particles and rays, becoming hotter.

The production of heat within the earth is declining, mainly because decay is decreasing the number of radioactive atoms. As the earth's heat production is slowing, its interior is cooling. During perhaps the next 5 billion or 10 billion years, this cooling will harden the

The drifting continents

The maps below illustrate the theory of continental drift. The map shows a single land mass—*Pangaea*—about 200 million years ago. The middle map shows Pangaea broken into the la masses *Laurasia* and *Gondwanaland,* and the present contine forming. The arrows show the direction in which the contine moved. The bottom map shows the continents today and whe they may drift during the next 50 million years, *black outlines.*

asthenosphere so much that plate motion will cease. After that occurs, volcanic eruptions will stop and ear quakes will become infrequent. The earth will be tectonically inactive.

History of tectonic theory

The theory of plate tectonics developed from a the of *continental drift,* presented in 1912 by German met orologist Alfred Wegener. Wegener's theory propose that the continents move about the surface of the eart It explained why the shape of the eastern coast of the Americas and that of the western coast of Africa seem fit together like pieces of a jigsaw puzzle. Evidence fo the drift came from the presence of certain rock depo its that indicate the continents have changed position

r time. For example, rock deposits from glaciers that ted hundreds of millions of years ago are found in ia, Australia, Africa, and South America, indicating these continents were once in a very cold climate, bably near the South Pole. Fossils of tree ferns and er tropical features in North America indicate that it once at the equator.

Vegener was not sure what caused continents to t, however. His theory of continental drift became a ject of much debate among scientists. Then, in the 0's, British physicist Harold Jeffreys proposed that the p interior of the earth was very strong and therefore ld not flow. As a result, most scientists rejected We- er's theory.

lowever, evidence supporting the theory of conti- tal drift gradually accumulated. In the late 1930's, erican geologist David Griggs demonstrated that ap- ently solid rock can flow slowly when subjected to h temperatures and pressures. In the 1940's and 0's, other researchers showed that the ocean floor tains much less sediment than would be expected if floor were a permanent depression. A permanent floor would have accumulated more sediment due the erosion of soil from the continents. The oldest -floor rocks that could be found were less than 150 ion years old.

the 1950's, scientists developed techniques for dying rock magnetism that enabled them to deter- e the positions of the continents millions of years . By the late 1950's, scientists completed mapping a em of ocean ridges extending for about 37,000 miles 000 kilometers) and reaching nearly around the ld.

the late 1950's, scientists discovered that most hquakes occur along lines parallel to ocean ridges trenches. In 1960, Harry H. Hess, an American geolo- , proposed a theory of what came to be called sea- r spreading. In 1967, American geophysicist Jason rgan and British geophysicist D. P. McKenzie inde- dently proposed the idea that the earth's surface sists of a number of movable plates. The following r, American earth scientists Bryan L. Isacks, Jack E. ver, and Lynn R. Sykes combined the idea of sea-floor eading with new results from earthquake detection proposed that rigid plates of lithosphere move ut on a soft, flowing asthenosphere.

1969, the drillship *Glomar Challenger* completed its scientific cruise. Material drilled from various loca- s on both sides of the Mid-Atlantic Ridge indicated the age of the ocean crust was exactly as predicted he analysis of paleomagnetism and sea-floor spread- This discovery and the continuing accumulation of er evidence convinced most earth scientists that the ory of plate tectonics is valid. Mark Cloos

van, Walter. *Continents in Motion.* 2nd ed. Am. Inst. of ysics, 1991.

Plateau is a raised area of relatively flat land. Some plateaus were originally *plains* (low, flat lands) produced by water erosion. Forces within the earth pushed the plains upward, creating the plateaus. Other plateaus lie on rocks that formed in a horizontal arrangement. Many such rocks formed from lava.

Streams often cut deep valleys into plateaus. Valleys with steep sides are known as *canyons.* The awesome Grand Canyon in Arizona, for example, is cut into the Colorado Plateau. Closely spaced rivers may cut a plateau so much that only a small portion of its original surface remains. Such cutting may form peaks known as *erosion mountains.* Rivers formed the Catskill Mountains in New York by cutting into the Appalachian Plateau.

Major plateaus occur at many elevations. The Plateau of Tibet in Asia has an average elevation of about 14,800 feet (4,500 meters). The Altiplano in Bolivia has an aver- age elevation of 13,100 feet (4,000 meters); the Plateau of Mexico, 6,500 feet (2,000 meters). Lower plateaus are in Iran, east and southwest Africa, India, and central Asia. The world's largest plateau, in Antarctica, has an area of about 4,900 square miles (12,700 square kilometers).

Plateaus in many humid regions, such as in Spain and France, provide excellent grazing lands for sheep and cattle. Plateaus of the Appalachian region have valuable deposits of coal. David S. McArthur

Platelet. See **Blood** (Platelets; Controlling bleeding).

Plateosaurus, *PLAT ee uh SAWR uhs,* was one of the largest and most widespread early dinosaurs. It lived about 220 million years ago, during the last part of the Triassic Period, in what is now western Europe.

Plateosaurus measured about 26 feet (8 meters) long and weighed up to 4 tons (3.6 metric tons). The dinosaur usually walked on all fours, but it could stand on its powerful hind legs to reach the tree leaves that it ate. *Plateosaurus's* five-fingered hands could grasp food. One finger on each hand had a big curved claw that the animal held above the ground while walking. Scientists think *Plateosaurus* used its claws to dig up vegetation and to defend itself. The dinosaur also had a long, thick tail that it held off the ground.

Plateosaurus's small, narrow head possessed an elon- gated snout and was set at the end of a long, slender neck. The jaw held many leaf-shaped teeth for chopping up plant material. It may also have used *gastroliths,* or stones in its digestive system, to further grind its food.

The German scientist Christian Erich Hermann von Meyer named *Plateosaurus* in 1837. Since then, scien- tists have uncovered large *bone beds* containing the re- mains of many animals. These finds suggest that *Pla- teosaurus* lived or traveled in herds, possibly to avoid seasonal droughts. David B. Weishampel

Platform tennis is a game in which the players—usually two on each side—use paddles to hit a ball back and forth over a net. The game is played outdoors on a raised court enclosed by a tight wire screen that meas- ures 12 feet (3.7 meters) high. The paddles are larger than those used in table tennis, and they have small round holes in the striking surface. The players use yel- low balls made of sponge rubber.

A platform-tennis court measures 44 feet (13 meters) long and 20 feet (6 meters) wide, and is laid out on a

WORLD BOOK photo by Steinkamp/Ballogg

Platform tennis is played with large paddles and a sponge rubber ball. The raised court is surrounded by a high wire fence.

playing area of 60 feet (18 meters) by 30 feet (9 meters).

The game is played and scored like tennis, with two important differences. A player has only one serve, rather than two as in tennis. Also, a player may return a ball that has landed in the court and bounced against the wire fence. The ball must be returned before it hits the platform a second time. See **Tennis.**

Platform tennis originated in 1928 in Scarsdale, New York. It was played mainly in the northeastern United States until the 1960's, when it began to gain nationwide popularity. The game attracts many players during the winter because it can be played in cold weather and snow can be swept off the platform.

Critically reviewed by the American Platform Tennis Association

Plath, Sylvia (1932-1963), was an American poet and fiction writer. Her works emphasize her sharp insights, ironic wit, and painful feelings. They are especially sympathetic to the plight of women, young people, artists, misfits, and rebels. Plath died young, but she is generally considered one of the most powerful American writers to have emerged since the 1940's.

Plath's poems employ vivid, memorable images to depict a world of anguish. "Daddy" dramatizes the hate and love a young woman feels for her father, who died when she was 10. "Medusa" tells of a daughter's troubled relationship with her mother. In "The Jailer," a wife expresses anger at her brutal, self-centered husband. Poems such as "Ariel" and "Lady Lazarus" explore feelings of despair. "Three Women" presents the thoughts of women as they feel the pain and joy of childbirth.

Plath's fiction, like her verse, frequently explores the dark side of modern life, though usually with humor. In *The Bell Jar* (1963), a college student comes to see her friends as hypocrites and her own values as false. Following a suicide attempt, the student is able to discover new and more satisfying reasons for living. Plath's short stories, collected in *Johnny Panic and the Bible of Dreams* (1977), focus on the central characters' feelings of loneliness and uncertainty.

Plath was born on Oct. 27, 1932, in Boston. Her fathe died when she was a young girl, and her mother worked hard to earn a living. Plath graduated from Smith College in 1955. She married British poet Ted Hughes in 1956. Plath committed suicide at the age of

Though little known at the time of her death, she be came famous with the publication of *Ariel* (1965), a col lection of her poems. *The Collected Poems* (1981) won the Pulitzer Prize for poetry. Plath's writings include a volume of letters to her mother, *Letters Home* (1975); and *The Unabridged Journals of Sylvia Plath:1950-1962* (2000). Steven Gould Axelrod

Platinum, *PLAT uh nuhm* (chemical symbol, Pt), is a precious, silver-white metal that is even more valuable than gold. Its atomic number is 78, and its atomic weig is 195.078. Platinum is one of the heaviest substances known. A given quantity of platinum weighs about 21 times as much as an equal quantity of water.

Properties. Platinum has many special characteristi that make it valuable. Only gold and silver are easier to shape than platinum. It can be shaped and worked in a most every possible way. It can be drawn into fine wir or it can be hammered into thin sheets.

Platinum does not corrode or tarnish when exposed to air because it does not combine readily with oxyge or sulfur compounds found in air. Strong acids that dis solve most metals do not attack platinum. Platinum dis solves in a mixture of nitric and hydrochloric acid calle *aqua regia* (see **Aqua regia**).

Platinum has a relatively high melting point of 1772 The metal combines readily with arsenic, phosphorus, and silicon. Platinum also forms alloys with most other metals. The most useful alloys are formed with iridium nickel, osmium, palladium, rhodium, and ruthenium.

Uses. Chemical laboratories often use platinum con tainers because the metal resists heat and chemicals. F the same reason, platinum parts are sometimes used i large-scale production equipment.

Platinum serves as an effective *catalyst,* a substance that speeds up chemical reactions. Automobile manufacturers use platinum in an emission-control device called a *catalytic converter.* The platinum helps to convert certain harmful pollutants into nonpollutants (see **Catalytic converter**). The oil industry also uses platinu to help break down *fractions* (parts) of petroleum to pr duce gasoline of higher octane number (see **Petroleu** [Refining petroleum]). Platinum is also used as a catalys in making various chemicals, such as acetic acid and n tric acid (see **Catalysis**).

The glass industry uses platinum to make dies for fiberglass. Platinum is a favorite material for use in expensive jewelry. Its strength, hardness, color, and freedom from tarnish make it ideal for gem settings. Delicate designs can be made in platinum settings. Platinu is also used on the best surgical instruments.

An alloy of platinum with iridium makes an excellent surface for fine engravings. This same platinum-iridiun alloy is used in making standards of weights and meas ures, contact points for electrical equipment, and the tips of fountain pens. Platinum salts are used in some photographic prints. Certain chemical compounds tha contain platinum are sometimes used to treat cancer.

roduction. The Italian scientist Julius Scaliger dis-
ered platinum in 1557. But fairly large quantities were
discovered until about 1750, when the Spaniards
nd deposits of platinum ore in South America. They
ed the metal *platinum,* from their word *plata,* mean-
silver. The ore, called *native,* or crude, platinum, usu-
occurs in beds of gold-bearing sand. Miners call it
te gold. Native platinum contains from 60 to 85 per-
t pure platinum. Platinum is also obtained from ores
hich it is combined with sulfur or arsenic.

he small, irregular grains that contain the ore also
r other rare metals, such as iridium, osmium, palladi-
rhodium, and ruthenium. These five metals and plat-
n are known as the *platinum-group metals.* Grains
bear platinum-group metals also contain small
unts of iron, copper, chromium, and titanium.
asionally, a large nugget of native platinum will be
nd. In 1843, a lump weighing over 21 pounds (9.5 kilo-
ns) was found in Russia.

outh Africa is the leading platinum-producing coun-
Other producers include Canada, Colombia, Russia,
the United States.

lmost all the platinum produced within the United
es comes from the process of refining copper and
d. Small amounts of platinum occur in copper-bear-
deposits in Arizona and New Mexico.

to, *PLAY toh* (427?-347? B.C.), was a philosopher and
cator of ancient Greece. He was one of the most im-
tant thinkers and writers in the history of Western
ure.

Plato's life

ato was born in Athens. His family was one of the
est and most distinguished in the city. His mother,
ctione, was related to the great Athenian lawmaker
on. His father, Ariston, died when Plato was a child.
ctione married her uncle, Pyrilampes, and Plato was
ed in his house. Pyrilampes had been a close friend
supporter of Pericles, the statesman who brilliantly
Athens in the mid-400's B.C.

s a young man, Plato wanted to become a politician.
04 B.C., a group of wealthy men, including two of
's relatives—his cousin Critias and his uncle
rmides—established themselves as dictators in
ens. They invited Plato to join them. However, Plato
sed the offer because he was disgusted by the
up's cruel and unethical practices. In 403 B.C., the
enians deposed the dictators and established a
ocracy. Plato reconsidered entering politics. But he
again repelled when his friend, the philosopher
rates, was brought to trial and sentenced to death in
B.C. Deeply disillusioned, Plato left Athens and trav-
l for a number of years.

387 B.C., Plato returned to Athens and founded a
ool of philosophy and science that became known as
Academy. The school stood in a grove of trees that,
rding to legend, was once owned by a Greek hero
ed Academus. Some scholars consider the
demy to have been the first university. Such subjects
stronomy, biological sciences, mathematics, and po-
al science were investigated there. Except for two
s to the city of Syracuse in Sicily in the 360's B.C.,
Plato lived in Athens and headed the Academy for the
rest of his life. His most distinguished pupil at the
Academy was the Greek philosopher Aristotle (see
Aristotle).

Plato's writings

The dialogues. Plato wrote in a literary form called
the *dialogue.* A dialogue is a conversation between two
or more people. Plato's dialogues are actually dramas
that are primarily concerned with the presentation, criti-
cism, and conflict of philosophical ideas. The characters
in his dialogues discuss philosophical problems and of-
ten argue the opposing sides of an issue. Plato achieved
a dramatic quality through the interaction of the person-
alities and views of his characters. These dramas of ideas
have much literary merit. Many scholars consider Plato
the greatest prose writer in the Greek language—and
one of the greatest in any language.

Plato's better-known dialogues include *The Apology, Cratylus, Crito, Euthyphro, Gorgias, The Laws, Meno, Parmenides, Phaedo, Phaedrus, Protagoras, The Republic, The Sophist, The Symposium, Theaetetus,* and *Timaeus.* A complete edition of Plato's works, collected
in ancient times, consists of 36 works—35 dialogues and
a group of letters. Scholars today generally agree that
about 30 of the dialogues and several of the letters were
actually written by Plato. Scholars have also determined
to a great extent the order in which the dialogues were
written. Thus, Plato's development as a writer and
thinker can be traced.

Detail of *School of Athens* (1510-1511); The Vatican, Rome (SCALA/Art Resource)

The Greek philosopher Plato, *left,* appears with his pupil Aristotle, as pictured by the painter Raphael, in a wall fresco at the Vatican in Rome. Aristotle was greatly influenced by the philosophy of his teacher.

The early dialogues are dominated by Socrates, who appears as a major figure in each. These dialogues include *Charmides, Euthyphro, Ion,* and *Laches.* In these dialogues, Socrates questions people who claim to know or understand something about which Socrates claims to be ignorant. Typically, Socrates shows that the other people do not know what they claim to know. Socrates does not provide answers to the questions. He shows only that the answers proposed by the other characters are inadequate. Most scholars consider these so-called *Socratic dialogues* to be fairly accurate portrayals of the actual philosophic style and views of Socrates. See **Socrates** (The Socratic method).

The later dialogues. In the later dialogues, Plato uses the character of Socrates merely as his spokesman. These dialogues include *The Republic, The Sophist,* and *Theaetetus.* In these works, Socrates criticizes the views of others and presents complex philosophical theories. Thus, the later dialogues offer more complete and positive answers to questions being considered than do the early dialogues. But they lack much of the dramatic and literary quality of the earlier writings.

Plato's philosophy

The theory of forms. Many of Plato's dialogues try to identify the nature or essence of some philosophically important notion by defining it. The *Euthyphro* revolves around a discussion and debate of the question, "What is piety?" The central question of *The Republic* is, "What is justice?" The *Theaetetus* tries to define knowledge. The *Charmides* is concerned with moderation, and the *Laches* discusses valor. Plato denied that a notion, such as *piety* (reverence), could be defined simply by offering examples of it. Plato required a definition of a notion to express what is true of, and common to, all instances of that notion.

Plato was interested in how we can apply a single word or concept to many different things. For example, how can the word *table* be used for all the individual objects that are tables? Plato answered that various things can be called by the same name because they have something in common. He called this common factor the thing's *form* or *idea.*

According to Plato, the real nature of any individual thing depends on the form in which it "participates." For example, a certain object is a triangle because it participates in the form of triangularity. A particular table is what it is because it participates in the form of the table.

Plato insisted that the forms differ greatly from the ordinary things that we see around us. Ordinary things change, but their forms do not. A particular triangle may be altered in size or shape, but the form of triangularity can never change. In addition, individual things only imperfectly approximate their forms, which remain unattainable models of perfection. Circular objects or beautiful objects are never perfectly circular or perfectly beautiful. The only perfectly circular thing is the form of circularity itself, and the only perfectly beautiful thing is the form of beauty.

Plato concluded that these unchanging and perfect forms cannot be part of the everyday world, which is changing and imperfect. Forms exist neither in space nor time. They can be known only by the intellect, not by the senses. Because of their stability and perfection, the forms have greater reality than ordinary objects observed by the senses. Thus, true knowledge is the knowledge of forms. These central doctrines of Plato's philosophy are called his *theory of forms* or *theory of ideas.*

Ethics. Plato based his ethical theory on the propos tion that all people desire happiness. Of course, peop sometimes act in ways that do not produce happiness But they do this only because they do not know what tions will produce happiness. Plato further claimed th happiness is the natural consequence of a healthy stat of the soul. Because moral virtue makes up the health the soul, all people should desire to be virtuous. Plato said that people sometimes do not seek to be virtuou but only because they do not realize that virtue produces happiness.

Thus, for Plato, the basic problem of ethics is a prol lem of knowledge. If a person knows that moral virtue leads to happiness, he or she naturally acts virtuously. Plato differed from many Christian philosophers who have tended to view the basic problem of ethics as a problem of the will. These philosophers argue that oft people know what is morally right, but face their grea est problem in *willing* to do it.

Plato argued that it is worse to commit an injustice than to suffer one, because immoral behavior is the symptom of a diseased soul. It is also worse for a pers who commits an injustice to go unpunished than to b punished, because punishment helps cure this most s rious of all diseases.

Psychology and politics. Plato's political philosop like his ethics, was based on his theory of the human soul. He argued that the soul is divided into three part (1) the rational part, or intellect; (2) the spirited part, or will; and (3) appetite or desire. Plato argued that we know the soul has these parts because they occasiona conflict with each other. For example, a person may d sire something but fight this desire with the power of the will. In a properly functioning soul, the intellect—t highest part—should control the appetite—the lowest part—with the aid of the will.

Plato described the ideal state or society in *The Republic.* Plato wrote that, like the soul, this state or society has three parts or classes: (1) the philosopher king who govern the society; (2) the guardians, who keep order and defend the society; and (3) the ordinary citizens, farmers, merchants, and craftworkers who provi the society's material needs. The philosopher kings re resent the intellect, the guardians represent the will, a the ordinary citizens represent the appetites. Plato's ideal society resembles a well-functioning soul becau the philosopher kings control the citizens with the aid the guardians.

Immortality of the soul. Plato believed that thoug the body dies and disintegrates, the soul continues to live forever. After the death of the body, the soul migrates to what Plato called the *realm of the pure form* There, it exists without a body, contemplating the form After a time, the soul is reincarnated in another body and returns to the world. But the reincarnated soul retains a dim recollection of the realm of forms and year for it. Plato argued that people fall in love because the recognize in the beauty of their beloved the ideal form of beauty that they dimly remember and seek.

n the *Meno,* Plato has Socrates teach an ignorant sl e boy a truth of geometry by simply asking a series o questions. Because the boy learns this truth without b ng given any information, Plato concluded that learn- ir consists of recalling what the soul experienced in th realm of the forms.

rt. Plato was critical of art and artists. He urged strict c sorship of the arts because of their influence on m lding people's characters. Using his theory of forms, Pl o compared artists unfavorably with craftworkers. He d lared that a table made by a carpenter is an imper- fe copy of the ideal form of a table. A painting of a ta e is thus a copy of a copy—and twice removed from th reality of the ideal form.

lato claimed that artists and poets cannot usually ex- p n their works. Since artists do not even seem to k w what their own works mean, Plato concluded that th y do not create because they possess some special k wledge. Rather, he believed that artists create be- c se they are seized by irrational inspiration, a sort of "c ine madness."

Plato's place in Western thought

fter Plato died, his nephew Speusippus took over th leadership of the Academy. The school operated un- ti .D. 529. That year, the Byzantine Emperor Justinian I c sed all the schools of philosophy in Athens because h felt they taught paganism. However, Plato's influence w s not confined to the Academy. Plato's philosophy d eply influenced Philo, an important Jewish philoso- p er who lived in Alexandria shortly after the birth of C ist. During the A.D. 200's in Rome, Plotinus devel- o ed a philosophy based on Plato's thought. This new v sion of Plato's philosophy, known as *Neoplatonism,* h great influence on Christianity during the Middle A es. See **Plotinus; Neoplatonism.**

lato dominated Christian philosophy during the early M ddle Ages through the writings of such philosophers a Boethius and Saint Augustine. During the 1200's, Aris- t e replaced Plato as the greatest philosophical influ- e e on the Christian world. A revival of interest in Plato d veloped during the Renaissance. During the 1400's, th Medici family, famous patrons of the arts, estab- li ed a Platonic Academy in Florence as a center for the s dy of Plato's philosophy.

n the mid-1600's, an important group of English philosophers at Cambridge University became known as the Cambridge Platonists. They used the teachings of Plato and the Neoplatonists to try to harmonize reason with religion. Ivan Soll

Platte River, *plat,* is the most important river in Nebraska and one of the largest branches of the Missouri River. The Platte River is formed by the union of the North Platte and South Platte rivers, both of which begin in the mountains of Colorado. The two rivers join near the city of North Platte, in western Nebraska (see **Nebraska** [physical map]). From this junction, the Platte River flows east and empties into the Missouri at Plattsmouth.

The North Platte flows 618 miles (995 kilometers), and the South Platte is 424 miles (682 kilometers) long. The main stream is about 310 miles (499 kilometers) long. The Platte and its branches drain a region of about 90,200 square miles (233,600 square kilometers). The Platte is too shallow for navigation. However, its valley provides a flat pathway, which has been followed by pioneers, the Union Pacific Railroad, and the Interstate 80 highway. David Wishart

Platypus, *PLAT uh puhs,* is one of only two mammals that reproduce by laying eggs. The echidna is the other. Platypuses are often called *duckbills* because they have a broad, flat, hairless snout similar to a duck's bill.

Platypuses live along streams in Australia. They have webbed feet and a broad, flat tail that aid in swimming. The platypus uses its bill to scoop up worms, small shellfish, and other animals from the bottom of streams. Adult platypuses lack teeth. They crush their food with horny pads at the back of the jaws. Platypuses grow from 16 to 22 inches (41 to 56 centimeters) long, includ-

Robin Smith, Photographic Library of Australia

The platypus has a broad, flat tail and webbed feet that aid in swimming. It lives along streams in Australia and is often called the *duckbill* because its snout resembles the bill of a duck. The platypus and the echidna are the only mammals that lay eggs.

ing a tail of 4 or 5 inches (10 to 13 centimeters). They weigh about 5 pounds (2.3 kilograms) but appear heavier because of their thick coat of brown fur.

The platypus has claws on its front and hind feet, but the webs of the front feet can be extended beyond the claws. The platypus folds these webs against the palms when walking on land or digging in the ground. Male platypuses also have a hollow clawlike *spur* behind each ankle. The spurs are connected to poison glands, which enlarge during the mating season. Scientists believe the male platypuses might use the spurs for defense.

Platypuses live in burrows that they dig in the banks of streams. The burrows may be as long as 85 feet (26 meters). Except for female platypuses with their young, each animal lives in its own burrow. During the mating season, the female platypus builds a nest of leaves and grass at the end of her burrow. Before laying her eggs, she blocks the entrances to the burrow with dirt. Female platypuses lay from one to three eggs at a time. The eggs measure about $\frac{1}{2}$ inch (1.3 centimeters) in diameter and have a leathery shell. Platypus eggs hatch after about 10 days. Young platypuses remain in their mother's burrow for about four months and feed on their mother's milk.

At one time, platypuses were hunted for their fur. Since the 1920's, however, the killing of platypuses has been prohibited by law.

Scientific classification. The platypus makes up the family Ornithorhynchidae in the mammalian order Monotremata. Its scientific name is *Ornithorhynchus anatinus.* Michael L. Augee

See also **Mammal** (picture: Monotremes).

Plautus, *PLAW tuhs* (254?-184 B.C.), was an important Roman writer of comedy. His plays are versions of Greek New Comedy, which emphasized young men in love with slave girls, mistaken identities, cunning servants, and deceived masters. Plautus added earthy Italian comic elements and his own boisterous wit. Subtle techniques of plot construction and characterization did not concern him as much as producing laughter. He was a master of dialogue, writing a lively stream of puns, love talk, and abuse.

Plautus wrote many plays, of which 21 have survived. *Amphitruo* is a mythological story about the god Jupiter fathering Hercules with a human man's wife. In *Menaechmi,* two long-separated brothers find each other after great confusion. In *Casina,* father and son are rivals for the same girl.

Titus Maccius Plautus was born in Sarsina, Italy. He apparently worked as a stagehand before turning to playwriting. Anthony A. Barrett

Play. See **Drama; Theater.**

Play, in recreation, is any activity performed for amusement. Although people engage in play mainly to enjoy themselves, play also contributes to the physical and mental health of individuals. For example, many people increase their physical fitness by swimming or hiking. Many people also improve their intellectual skill by playing word games or solving puzzles.

Play activities fall into one of three general groups—(1) motor play, (2) intellectual play, or (3) sensory play. Motor play is physical exercise, such as skating or playing volleyball. Intellectual play primarily involves mental activity, as in playing chess. Sensory play includes spectator activities, such as attending sports events.

L. L. T. Rhodes, Click/Chi

Intellectual play involves mental activity. Chess players, *abo*[ve,] must use their powers of concentration in order to evaluate a large number of possible moves and strategies.

Play takes countless forms. A person may bounce a ball alone or join in a game of basketball with several other people. Play activity may or may not be planned ahead of time. It can take place anywhere, from in an individual's mind to areas designed specifically for play, such as sandboxes, playgrounds, recreation rooms, ar[nd] athletic fields.

Some play activities are popular with both children and adults. Other activities appeal primarily to people [of] certain age groups. Children often take part in play tha[t] requires a great deal of imagination, such as playing with dolls or dressing up and pretending to be adults. Adult play activities generally involve more structured types of recreation, such as hobbies, sports, and game[s.]

For a child, playing is a form of self-expression and [a] significant part of social development. Children begin [to] play long before they can communicate effectively wit[h] words. Through playing, they express their ideas, moods, problems, and personalities to other people. Children learn to interact with one another by sharing toys or playing games that stress personal cooperatio[n,] such as tag or hide-and-seek. When they are older, the[y] develop teamwork skills by playing competitive sports like volleyball.

For an adult, playing is a way of relaxing during leisure time. Play activities help relieve pressures caused by the tensions of daily life. Roger A. Lancaster

Children at a playground climb and slide on the equipment. The grass field behind the equipment is used for games and sports for older children and adults. City planners usually provide for playgrounds in communities, and most schools have them.

Pıyground is an outdoor area set aside for play. Playg unds were first started for children. But people of all a s enjoy the many different playground activities offed today.

 mall children can play informally in sand piles, and o seesaws and swings. Older boys and girls may play o practice a variety of games and sports on the playg und. Adults may participate in such games as tennis, b minton, and horseshoes. Many playgrounds have s ficient space for basketball, baseball, and even footb l and soccer. Some playgrounds have outdoor swimm g pools.

 laygrounds often become a center of community acti ty. Parents come to watch competitive contests and c er special events. Holiday celebrations, such as those c the Fourth of July and Labor Day, are often held in p ygrounds. Many schools hold yearly play days on p ygrounds.

 efore 1900, children played on the lawns of their h mes, in vacant lots, and in the streets. The movement f public playgrounds was started shortly before 1900 b Jacob Riis, a New York City newspaperman. Riis and c ers recognized the great need for play space and r reation activities in the growing cities. The slum a as had no lawns or vacant lots for play. Most of the e ly schools did not have land around them that could b used for play. By 1899, Boston had 21 sand lots for s all children.

 Other Eastern cities followed Boston's example, and s n sand gardens and playgrounds were being organi d in several cities. In 1889, the Charlesbank Outdoor (mnasium opened in Boston. This recreation area pro ed apparatus for gymnastics, a running track, and s ice for games for older boys and men. A section was a led two years later for women and girls.

 Today, practically all schools have playgrounds. Cities h e several playgrounds located in various community tricts. City playgrounds are usually under the direct n of park and recreation boards. Sometimes they are developed and controlled jointly by park districts, school boards, and recreation commissions. Playgrounds are usually provided for in modern city planning. Building ordinances often require that new communities include space for parks and playgrounds.

Playground programs are planned and conducted by trained playground leaders who usually have majored in physical education and recreation in college. They learn how to plan and conduct playground activities according to the educational, growth, and developmental needs of boys and girls. Walter Harold Gregg

Playing cards. See **Card game**.

Plea bargaining is a practice in which the defendant in a criminal case agrees to plead guilty instead of going to trial. In some cases, the prosecuting attorney promises to drop one or more charges or to substitute a less serious charge in exchange for a guilty plea. Such a procedure is called *charge bargaining.* In a process called *sentence bargaining,* the prosecutor promises to recommend that the accused receive a lighter sentence than ordinarily would be given. In the United States, about 90 per cent of all defendants plead guilty, most as a result of plea bargaining. A defendant who engages in bargaining is sometimes said to be "copping a plea."

The government saves time and money by plea bargaining rather than deciding each case by trial. Many lawyers and other experts on criminal justice favor plea bargaining because it allows district attorneys to vary punishment, depending on the individual circumstances of the crime. Other supporters believe that a lawbreaker who openly acknowledges guilt has shown regret and deserves a lighter sentence.

Many critics of plea bargaining believe it allows large numbers of criminals to be punished less severely than they deserve. Other opponents fear that the procedure jeopardizes a defendant's right to be considered innocent until proved guilty. They argue that plea bargaining

may force even innocent persons to agree to a criminal charge because of a fear of going to trial. As a result of such criticisms, many states have established rules to prevent abuse of the system. In some states, lawyers must report in open court the promises made during plea-bargaining sessions. Jack M. Kress

Plebeians, *plih BEE uhnz,* were commoners in the early Roman Republic. The plebeians included freed slaves, peasant farmers, and dependents of *patricians* (aristocrats). It is not known how the difference between plebeians and patricians first arose, but it existed by the early 500's B.C. Plebeians who owned property served in the army and, like the rest of their class, were denied many rights. For many years, they could not hold public office, vote on laws, or become priests. They were forbidden to marry persons not of their class. Judges often treated the plebeians unfairly.

Early in the 400's B.C., the plebeians threatened to refuse to fight unless they were allowed to choose their own *tribunes* (officials). The plebeians were given the right to elect tribunes who could *veto* (reject) unfair acts of judges and lawmakers. Later, in 445 B.C., the plebeians received the right to marry patricians. In 367 B.C., they were allowed to run for the office of *consul* (chief government official). By 300 B.C., they had been declared eligible for the priesthoods and other offices. In 287 B.C., the *comitia tributa* (assembly of all the people—plebeians and patricians alike) was given the power to make laws that bound everyone.

Wealthy plebeians then began joining the patricians to form a new upper class. But tribunes and the *comitia* remained to protect the poor classes of Rome until the end of the republic, in 27 B.C. D. Brendan Nagle

See also **Patricians; Praetor; Tribune.**

Plebiscite, *PLEHB uh syt,* is a vote of the people on any question. But the term has come to mean the vote of inhabitants in a territory to choose the nation that will govern them. The plebiscite was first used during the 1790's when the citizens of Nice and Savoy voted for or against union with France.

Modern plebiscites are almost always under international supervision. In 1975, for example, the United Nations (UN) sent observers to witness a plebiscite in the Northern Mariana Islands in the Pacific Ocean. The islands were governed by the United States as part of a UN trust territory. In the plebiscite, the people voted to become a commonwealth of the United States. Plebiscites also decided the status of the Saar in Europe and British Togoland in Africa.

Plebiscites are intended to give territories freedom of choice, but interested nations sometimes try to influence the vote by military pressure. In any case, plebiscites have marked a long step forward in permitting people of certain territories some freedom in choosing their form of government. Robert Agranoff

Plecoptera, *pluh KAHP tuh ruh,* is an order of insects that lay their eggs in water. The young live in streams or along the rocky shallows of ponds and lakes. They form a large part of the diet of trout and other fish. The adults have wings but do not fly well and seldom wander far from their breeding place. The insects are known as *stoneflies* because the young find shelter under stones. See also **Stonefly.**

Pledge. See **Oath.**

Pledge of Allegiance is a solemn promise of loyalt to the United States. It reads:

> I pledge allegiance to the flag of the United States of America and to the Republic for which it stands, one Nation under God, indivisible, with liberty and justice for all.

Public-school children first recited the pledge as the saluted the flag during the National Public Schools Cel bration held in 1892 to mark the 400th anniversary of th discovery of America. The original pledge was most likely written by Francis Bellamy (1855-1931), though some people later claimed that James B. Upham (1845-1905) wrote the pledge. Both men were from Boston a worked for *The Youth's Companion.* A panel of schola gave the credit to Bellamy in 1939. The National Flag Conferences of the American Legion expanded the ori inal wording in 1923 and 1924. In 1942, Congress made the pledge part of its code for the use of the flag. In 1954, it added the words "under God." Whitney Smith

Pleistocene Epoch, *PLYS tuh seen,* was a geologic time period in the earth's history. Many earth scientists believe this epoch began about 2 million years ago an ended about 11,500 years ago. The Pleistocene Epoch i cluded numerous periods called *ice ages,* when ice sheets covered large regions of land. Anthropologists believe an early form of human being gradually developed into the modern form during the Pleistocene Epoch. See also **Ice age; Earth** (table: Outline of Earth's history); **Prehistoric people.**

Plekhanov, *plih KHAH nahf,* **Georgi Valentinovich,** *geh AWR gih VAH lehn TEE nah vihch* (1856-1918), was a leading advocate and interpreter of Marxi ideas in Russia during the late 1800's and early 1900's. Plekhanov, the youngest son of a minor noble, was bo on Dec. 11, 1856, in Gudalovka, near Tambov, Russia. A a young man, he joined a revolutionary movement that wanted to establish socialism in Russia. In 1880, he fled to Switzerland to escape arrest for his political activitie There, he became a follower of Karl Marx, the German founder of Communism.

Plekhanov adapted Marx's ideas to Russian conditio and projected a two-stage revolution to achieve a soci ist state. In the first stage, the working and middle clas es would defeat the Russian monarchy. In the second stage, the workers would overthrow the middle class and come to power.

In 1883, Plekhanov helped found the first Russian Marxist organization, the Emancipation of Labor group This group led to the formation of the Russian Social Democratic Labor Party in 1898. At its second convention in 1903, the party adopted a platform based on Plekhanov's theory of a two-stage revolution.

Plekhanov disagreed with V. I. Lenin, another Russia socialist, on many political questions. Their differences came to a head during World War I (1914-1918). Plekhanov wanted Russia to remain in the war and hel France and Britain to win. Lenin proposed to turn the war into a worldwide revolution. In 1917, Lenin and his followers seized power and established a Communist government in Russia. Helmut Gruber

Plessy v. Ferguson was a landmark decision of the Supreme Court of the United States concerning racial segregation. In this 1896 ruling, the court established the policy of "separate but equal" public facilities for

blacks and whites. The decision formed the basis of widespread segregation in the South for over 50 years.

The case began in 1892, when Homer A. Plessy challenged a Louisiana law that required separate but equal facilities for blacks and whites in railroad cars. John H. Ferguson, a criminal district court judge, overruled Plessy's plea that the law was unconstitutional. Plessy then brought action against Ferguson. Plessy argued that the law violated a clause of the 14th Amendment to the U.S. Constitution that guaranteed citizens equal protection of the laws. The Supreme Court ruled that the amendment did not seek to guarantee the social equality of all races. The court upheld the Louisiana law. Segregation of the races in the South continued, though facilities for blacks were nearly always inferior to those for whites. Stanley I. Kutler

Pleura, *PLUR uh,* is a thin membrane that lines the *thoracic cavity* (chest cavity) and covers the lungs. The part covering the lungs is called the *visceral pleura,* or *pulmonary pleura.* The remaining part, called the *parietal pleura,* lines the chest wall and covers the diaphragm. The two parts of the pleura unite at the root of the lung, where the *bronchus* (branch of the windpipe) and blood vessels enter the lung.

In a healthy person, the two parts of the pleura touch. They secrete a trace of watery fluid that lubricates their surfaces. Inflammation of the pleura, a condition called *pleurisy,* can cause fluid to accumulate between the two pleural surfaces, possibly compressing the lung underneath. If a hole develops in the surface of the lung, air enters the space between the pleural surfaces. This condition, called *pneumothorax,* may cause the lung to collapse. Robert A. Klocke

See also **Lung; Membrane; Pleurisy; Pneumothorax.**

Pleurisy, *PLUR uh see,* is a general term for inflammation of the *pleura,* a membrane that lines the inside of the chest and covers the lungs (see **Pleura**). The two surfaces of the pleura are normally moist and allow the lungs to move smoothly over the chest wall when a person breathes. When the pleura is inflamed, its surfaces become dry and rough and rub together. The inflammation stimulates pain receptors in the pleural lining of the inside of the chest and causes intense pain, made worse by coughing and deep breathing.

Pleuritic pain is often accompanied by *pleural effusion,* an accumulation of excessive amounts of liquid in the space between the two parts of the pleural membrane. In some cases, so much fluid collects in this cavity that the lungs become compressed and cannot inflate normally. Chills and fever, coughing, and difficulty in breathing may also accompany pleurisy.

Most cases of pleurisy occur as complications of pneumonia, tuberculosis, or other infectious diseases. Physicians must therefore treat the underlying disease in order to cure pleurisy. A doctor may prescribe drugs to relieve the pain of a person with pleurisy. In cases of pleural effusion, a physician may drain fluid from the patient's chest. Michael G. Levitzky

Plexus, *PLEHK suhs,* in anatomy, is a network of interwoven parts. In a nerve plexus, such as the *brachial plexus* that supplies the arm, there is a complex interweaving of nerve fibers. In a vascular plexus, made up of arteries, veins, or lymphatic vessels, the vessels are connected with each other. See also **Solar plexus.**

Delmas J. Allen

Plimsoll mark, *PLIHM suhl,* is a load-line marking on the side of a ship's hull. It shows the *draft* a ship can be safely loaded to under certain conditions. The draft is the depth to which a ship sinks in the water. The position of the marking depends on the type and size of the vessel. A ship loaded "down to the Plimsoll mark" carries the maximum weight of cargo. Any more cargo would lessen the ship's chances of a safe voyage.

The name comes from Samuel Plimsoll, a member of the British Parliament who was active in promoting the Merchant Shipping Act of 1876. This act was the first legislation to require a draft mark on the side of a vessel beyond which it could not be loaded.

South Street Seaport Museum

A Plimsoll mark, like the one being measured above, indicates how much cargo a ship can carry safely. A ship has the maximum cargo when the water level reaches the horizontal line.

Load-line regulations for American ships have been established by the United States Coast Guard as provided under the Load Line Act of 1929 and the Load Line Convention of 1966, an international treaty signed by the world's seagoing nations. These rules apply to deep-sea vessels of 150 gross tons or more.

The distance between the Plimsoll mark and the deck is the ship's "freeboard." Special markings were established in 1935 for Great Lakes and Atlantic and Pacific coast voyages. In 1973, Canada and the United States agreed on revised load-line regulations for ships traveling on the Great Lakes. Robert F. Beck

Pliny the Elder, *PLIHN ee* (A.D. 23 or 24-79), was a Roman writer. Pliny wrote many historical and technical works, but only his 37-volume *Natural History* has survived. Although this work was much used during the Middle Ages, its main value now is to show the state of scientific knowledge during Pliny's time. See **Geology** (The Romans).

Pliny was born in Novum Comum (now Como) in northern Italy. His given and family name was Gaius Plinius Secondus. As a lawyer, he held important public offices. He was commander of the fleet near Pompeii

when Mount Vesuvius erupted in A.D. 79, and he died there trying to help the refugees. His nephew, Pliny the Younger, was also a famous writer. Anthony A. Barrett

Pliny the Younger, *PLIHN ee* (A.D. 61 or 62-113?), was a Roman writer. He was the nephew of another Roman writer, Pliny the Elder. His most important works are his *Letters,* collected in 10 books. They show the life and interests of a Roman gentleman, scholar, and philanthropist. The letter addressed to the historian Tacitus gives a detailed account of the eruption of Vesuvius, and describes the death of his uncle. Pliny the Younger served as governor of Bithynia and Pontus, and wrote letters to the Emperor Trajan describing the Christians and asking what to do about them. These letters are the earliest accounts of Christians written by a pagan.

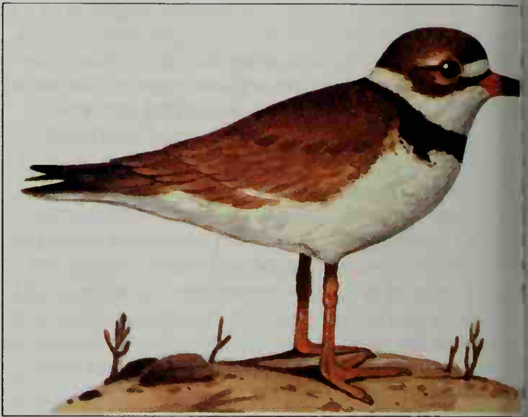
Pliny the Younger was born in Novum Comum. His given and family name was Gaius Plinius Caecilius Secundus. By the age of 20, he was considered one of the most learned people of his time. He studied under Quintilian and was a good orator. Anthony A. Barrett

Pliocene Epoch. See **Earth** (table: Outline of the earth's history).

PLO. See **Palestine Liberation Organization.**

Plot. See **Drama** (The structure of drama); **Literature** (Plot).

Plotinus, *ploh TY nuhs* (205?-270?), was the founder of a school of Greek philosophy known as *Neoplatonism.* He developed Neoplatonism from the philosophy of Plato (see **Neoplatonism**). Plotinus said that the material world is unreal, politics trivial, the body a temporary prison for the soul, and life a journey through a landscape of illusion. Reality lay "yonder" in a solitary perfect being, *The One,* the source of all truth, goodness, and beauty. He said pure souls may hope to "return" there. Sometimes this return occurred as a mystical vision. Plotinus believed he had experienced such a vision.



Plotinus may have been born in Egypt. He joined a military campaign to the East to try to learn more about Indian philosophy. Plotinus spent the last years of his life teaching in Rome. He disliked writing but dictated 54 lectures in six 9-lecture sets called the *Enneads.* His pessimism reflects only one side of Plato's philosophy—that in which philosophy is seen as a consolation or as an escape from the world. But this was the side most appealing to Romans of Plotinus's time. S. Marc Cohen

Plovdiv, *PLAWV dihf* (pop. 341,058), is Bulgaria's second largest city. Only Sofia has more people. Plovdiv is an agricultural, industrial, and railroad center. It lies on the Maritsa River (see **Bulgaria** [map]).

Plovdiv is Bulgaria's chief marketing center for tobacco and perfume. It has leather, metal, and textile industries, and it processes farm products. Plovdiv holds a major international trade fair twice a year.

By the 400's B.C., a Thracian town existed at what is now Plovdiv. Philip of Macedonia captured it in 341 B.C. From about the time of the birth of Christ until about A.D. 300, the town flourished as part of the Roman Empire. It later changed hands many times before the Ottoman Empire captured it in 1364. In 1878, Plovdiv became capital of Eastern Rumelia, a partly self-governing province in the Ottoman Empire. It united with the rest of Bulgaria in 1885. Vojtech Mastny

Plover, *PLUHV uhr* or *PLOH vuhr,* is the name of a group of shore birds found throughout the world. Plovers measure from 6 to 16 inches (15 to 41 centimeters) in length. They may be many colors, and the feathers are usually marked in various patterns. The head and neck often have dark markings. The wings are pointed and reach beyond the end of the tail.

WORLD BOOK illustration by John F. Eg

The semipalmated plover nests along shorelines in Alaska and Canada. It winters as far south as central Chile and Argentina. The bird is also known as the *ring-necked plover.*

A plover has a short, thick neck and a short bill. Unlike most other shore birds, plovers secure their food from the surface of the ground rather than by probing. Their food includes such animals as insects, worms, ar crabs. They also eat berries.

Plovers build their nests on the ground. The female plover usually lays four eggs. The spotted eggs are diffi cult to distinguish from pebbles around them. Feathers of newly hatched chicks are also marked with dark spots.

About 12 species of plovers live in North America. Two common species, the *black-bellied plover* and the *lesser golden-plover,* nest in arctic Alaska and Canada. The black-bellied plover has black and white feathers and a black breast and throat. Feathers of the lesser golden-plover are black and gold. This bird migrates as far as Hawaii and South America in winter.

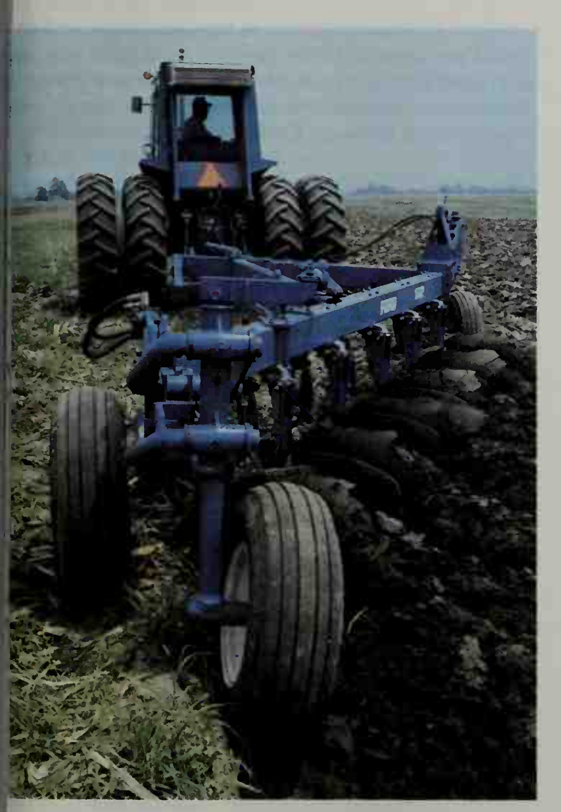
The *semipalmated plover,* or *ring-necked plover,* als nests in Alaska and Canada. It has a dark back, a white breast, and a black band across its neck. It winters as fa south as central Chile and Argentina. Other common North American plovers include the *snowy plover,* the *Wilson's plover,* the *mountain plover,* and the *killdeer.* The *piping plover* was once common on the Atlantic and Gulf coasts and along the Great Lakes. This species is now in danger of extinction. Fritz L. Knopf

Scientific classification. Plovers belong to the family Char driidae. The scientific name for the black-bellied plover is *Pluvi alis squatarola.* The lesser golden-plover is *P. dominica.* The semipalmated plover is *Charadrius semipalmatus,* and the piping plover is *C. melodus.*

See also **Animal** (picture: Animals of the polar regions); **Bird** (pictures: Birds of the Arctic; Birds of the seacoasts); **Killdeer.**

Plow is a tool that is used to prepare soil for planting. plow digs into the ground and pushes, cuts, and lifts th soil to break it up. Much of the food in the world come from crops that have been grown in plowed fields and

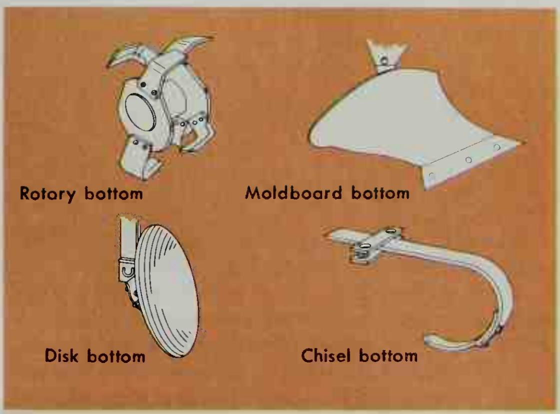
m food-producing animals that feed on such crops.



armers *till* (plow) the soil for many reasons. For ex-
ple, plowing reduces the hardness of the upper 6 to
nches (15 to 41 centimeters) of the earth's crust, mak-
seed planting easier. Tillage also aids planting by
ering up the *residue* (remains) of the previous crop
l by killing weeds and insects. In addition, air move-
nt into the earth increases, and oxygen can act more
ckly on organic matter in the soil to speed the re-
se of plant nutrients. Plants growing in the soil can
 take in more oxygen through their roots and thus
w more rapidly.

Kinds of plows

There are four chief kinds of plows: (1) the *tractor*
w, (2) the *walking plow,* (3) the *sulky plow,* and (4) the
g plow. In developed countries, almost all farmers
 a tractor plow. Most farmers in developing coun-
s use a walking plow. Sulky plows and gang plows
e almost disappeared from use. Practically all plows
d today are made of iron and steel, but some are
ilt of wood.



The tractor plow is pulled by a tractor. This type of
w has from 1 to 10 or more *bottoms* (furrowing
des) mounted on its frame. *Colters* (disk blades) can
o be mounted on the frame to cut residue.

The walking plow is pulled by horses, mules, or
n. The farmer must walk behind and hold the han-
s to guide the plow.

Ford Motor Company

ractor plow is pulled by a tractor. The plow shown above
 seven furrowing spades, called *bottoms.* It uses *moldboard*
ttoms, the most popular type of plow bottom.

WORLD BOOK illustration

Plow bottoms are manufactured in four main designs. The *rotary bottom* mixes crop residue with the soil. The *moldboard bottom* buries residue. The *disk bottom* tills hard, sticky, or stony land. The *chisel bottom* leaves residue on the surface.

The sulky plow has a seat and wheels, and so the farmer can ride while tilling. Horses pull the sulky plow, which was invented in 1875 by John Deere, an Illinois blacksmith.

The gang plow, a horse- or tractor-drawn plow, also allows the farmer to ride while tilling. It has two or more bottoms and three wheels. A gang plow can till as many furrows at a time as it has bottoms. A walking plow and a sulky can till only one at a time.

Kinds of plow bottoms

Farmers also classify plows according to the types of bottoms they have. There are four main kinds of plow bottoms: (1) the *moldboard,* (2) the *disk,* (3) the *chisel,* and (4) the *rotary.*

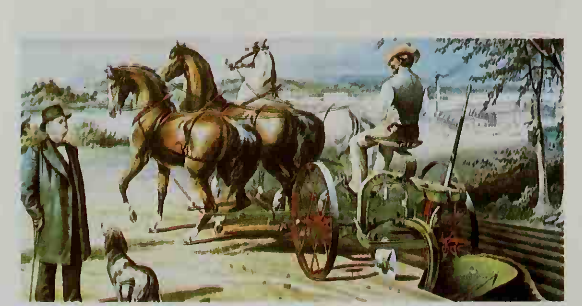
The moldboard plow bottom ranks as the most widely used type. A moldboard plow *molds* (covers and buries residue) as it tills. The moldboard bottom has three main parts: (1) the *share,* (2) the *landside,* and (3) the *moldboard.* They are bolted onto a frame called the *frog,* which holds them together in the shape of a three-sided wedge.

The share is the sharp edge that cuts the furrow slice loose from the ground. The share uses most of the power that is required to pull the plow bottom through the soil.

The landside fits behind the point of the share and below the moldboard. It slides along the land at the bottom of the furrow, where a slice of soil has been cut out, and stabilizes the plow.

The moldboard is located above and to the rear of the share. It turns the soil, breaks it up, and moves it to one side.

Farmers use four types of moldboards. A *stubble* moldboard is short and sharply curved. This type may be used for slow plowing in soils that *scour* (slide cleanly off the moldboard). A *general-purpose* moldboard has a longer curve, which makes it useful for average scouring conditions and plowing speeds. A *high-speed* moldboard has an even longer curve and can plow at higher speeds without throwing the soil too far to the side. A *slatted* moldboard consists of long



Giraudon/Art Resource

Egyptian farmers tilled their fields with wooden walking plows in 1300 B.C. They used oxen to pull the plows.

Detail of *American Farm Scenes #1: Spring* (1853), a hand-colored litho-graph by Frances Palmer, printed by Nathaniel Currier (Granger Collecti

The American farmer in 1853, like the ancient Egyptians, use a plow pulled by oxen. But this plow had a steel bottom.

John Deere

The sulky plow allowed farmers to ride while they plowed. John Deere, an Illinois blacksmith, invented this plow in 1875.

J. I. Case Compa

Steam-powered plows came into use in the early 1900's. Such machines were costly and hard to repair.

curved steel slats, which provide little surface area for sticky soils to cling to.

Other types of bottoms provide greater efficiency than moldboards in certain situations. The bottom of a *disk plow* consists of a disk-shaped blade designed to till hard, sticky, or stony land. The *chisel plow* has narrow, C-shaped bottoms. Chisel plows lift the soil without turning it over. This action leaves crop residue on the surface where it can reduce the *erosion* (wearing away) of soil that results from the movement of wind and water. A *rotary plow* has many bent rotating blades that mix residue with the soil.

History

The people of most prehistoric civilizations never tilled the soil. They merely punched holes in the ground with a stick to bury the seed and hide it from birds and rodents. Then, more than a million years ago, people discovered that plants grew better in soil that had been loosened. They began to use such objects as sharp sticks, rocks, bones, or shells to pry loose chunks of dirt before planting the seed.

The first plow was made about 8,000 years ago. A farmer sharpened one prong of a forked branch to turn the soil and probably hitched a person to the other prong. The farmer guided the implement by holding the branch's stump while the other person pulled. Later, oxen were used to pull the plow, and a pointed iron spade replaced the bottom prong. Ronald T. Schuler

See also **Deere, John; Farm and farming** (picture: Tillage and planting equipment).

Plum is a popular fruit that is eaten fresh or used to make jams, jellies, and preserves. Some types of plums are dried to make prunes (see **Prune**).

Plums grow on trees that range in height from 7 to 1 feet (2 to 5 meters). Plums have a smooth, thin skin surrounding a thick, juicy flesh. A hard pit in the center of the fruit contains one or two seeds. Plums may be hear shaped, oval, or round. Cultivated varieties measure

Kinds of plums

The three main kinds of plums are European, Japanese, and American. European plums are the most widely grown. Japane plums are firm and juicy. American plums are hardy and can grow in colder climates than European and Japanese plums.

WORLD BOOK illustrations by James Teas

f m 1 to $2\frac{1}{2}$ inches (25 to 64 millimeters) in diameter. ley may be black, blue, green, purple, red, or yellow, pending on the variety.

About $6\frac{1}{2}$ million short tons (6 million metric tons) of ims are produced in the world each year. The leading im-producing countries include China, Germany, and United States. The United States produces about 1 llion short tons (9 million metric tons) of plums each ir. California produces far more plums than all the ier states combined. In Canada, British Columbia and tario are the leading plum-growing provinces.

Kinds of plums. There are three main kinds of ıms: (1) European, (2) Japanese, and (3) American. ere are several *cultivars* (cultivated varieties) within ch type.

European plums, often called *domesticas,* originated southwestern Asia, but they have been grown in Euoe for more than 2,000 years. In the 1600's, European ıms were introduced into what is now Massachusetts. the 1700's, Spanish missionaries brought them to Calinia. Important cultivars include Bradshaw, Grand ke, Jefferson, Lombard, Reine Claude, and Stanley. rtain cultivars of European plums with high sugar ntent are primarily dried to make prunes.

Japanese plums are native to China, but they were st cultivated in Japan. In 1885, Luther Burbank, an nerican horticulturist, introduced them into California. panese plums are generally firm and juicy and are ually eaten fresh. Cultivars include Abundance, Burnk, Santa Rosa, and Shiro.

American plums grow on trees that were developed om wild plum trees of North America. The trees are t widely cultivated, but they can survive in much lder climates than European and Japanese plum trees n. Cultivars of American plums include Cheney, De to, Golden Beauty, and Monitor.

Growing plums. Growers produce plum trees by atching buds of commercially desirable cultivars onto a *otstock* (root system and stem from another plant). Tother they make a sturdier tree (see **Grafting**). For exnple, several species of American plum trees are usel as rootstocks for European and Japanese plums. owers plant plum trees about 20 feet (6 meters) apart id carefully prune them during the first few years of owth to form well-shaped trees.

Plum trees generally flower from one to five years ter planting. They produce beautiful white blossoms in e early spring that, if pollinated, develop into mature uit by late summer. Most cultivars of plum trees are *lf-unfruitful*—that is, they cannot produce fruit with eir own pollen and must be pollinated by another culvar within the same type. Both wild bees and bees om beehives that growers place in their orchards are portant for carrying pollen from tree to tree.

Diseases and pests. Major diseases that infect plum ees include the fungal diseases *black knot* and *brown t.* Growers control these diseases by removing and estroying infected parts of the trees, or by spraying the ees with fungicides. *Plum curculio* is a serious insect est that damages the fruit by laying eggs underneath e skin. This pest is controlled through the use of insecide sprays.

Scientific classification. Plums belong to the rose family, saceae. They are genus *Prunus.* The scientific name for the species to which European plums belong is *P. domestica.* Japanese plums are *P. salicina.* American plums are of several species, including *P. americana, P. nigra,* and *P. besseyi.*

James E. Pollard

See also **Drupe**; **Prune**; **Fruit** (table: Leading fruits in the United States).

Plumbago, *pluhm BAY goh,* also called *leadwort,* is the name of several garden plants and shrubs grown for their clusters of blue, white, or reddish-purple flowers. The flaring petals of each flower are joined at the center to form a long tube. The leaves are oval, shiny, and dark green. A species planted yearly in many northern gardens grows up to $1\frac{1}{2}$ feet (46 centimeters) high and has spikes of blue flowers. A shrubby species called *cape leadwort* grows in southern California and the Gulf States. It forms bushes or vines and is covered by blue or white flowers for much of the year. In northern states, the cape leadwort grows only in greenhouses.

Scientific classification. Plumbagos belong to the plumbago or leadwort family, Plumbaginaceae. The scientific name for the annual plumbago is *Plumbago caerulea;* the cape leadwort is *P. auriculata.* Walter S. Judd

Plumbing is a system of pipes that carries water into and out of a house or other building. The term comes from the Latin word *plumbum,* meaning *lead.* The ancient Romans used lead plumbing pipes. Today, most plumbing pipes are made of brass, cast iron, copper, plastic, or steel.

A plumbing system consists of two separate sets of pipes, a *water supply system* and a *drainage system.* The water supply system brings clean water to plumbing fixtures, including bathtubs, showers, sinks, and toilets. It also supplies clean water to such appliances as dishwashers, garbage disposers, hot-water heaters, washing machines, and water softeners. The drainage system carries away water and waste materials.

The water supply system and the drainage system both must function properly for a building's plumbing to be efficient and safe. Defects in a water supply system, such as leaking connections or dripping faucets, can cause damage to the system and waste a large amount of water. A drainage system that leaks or overflows creates a health hazard by spilling waste materials and the bacteria they contain.

The water supply system. Water for a plumbing system comes from two sources: (1) rivers and lakes, and (2) wells. Cities and towns draw water from these sources and pipe it to treatment plants, where it is purified. The purified water flows through large pipes called *mains,* which run under the streets. The mains connect with smaller pipes known as *service lines,* which lead into each building. In some rural and suburban areas, many houses and other buildings have private wells. See **Water** (City water systems).

The water supply system of every building has a *shutoff* valve. The shut-off valve normally remains open, permitting water to enter the building. The valve can be closed to turn off the water in order to repair the pipes or fixtures or in case of some other emergency. Each plumbing fixture and appliance also should have its own shut-off valve.

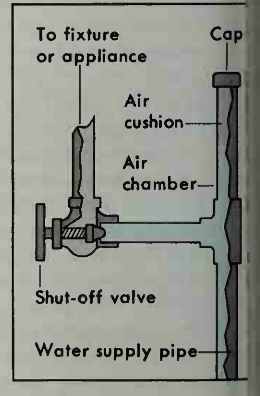
In many plumbing systems, a *water meter* attached to the service line measures the amount of water that is used in the building. The water company charges the

customer according to the amount of water used.

Water that flows into a building through the service line is cold. Pipes connected to the service line carry the water to all the plumbing fixtures and to the appliances that use cold water. One of the pipes brings water to the hot-water heater. Water enters the hot-water heater through a *cold-water inlet pipe.* The water is heated in a tank to a temperature of 120 °F to 150 °F (49 °C to 66 °C). The heated water is drawn from the top of the tank. It flows through a *hot-water outlet pipe* and is carried by branch pipes to the plumbing fixtures and appliances in the building that use hot water. The hot-water heater tank in most houses holds from 30 to 50 gallons (114 to 189 liters) of water. The tank is always full. As hot water is used, cold water enters the tank at the bottom to be heated.

The water in a plumbing system's water supply pipes is always under pressure, even when it is not running. The fixtures and appliances have valves that hold back the water until it is needed. When the fixture or appliance is turned on, the valve lets water flow in. The valve stops the flow of water when the fixture or appliance is turned off.

The drainage system. After water has been used, it flows out of the building through the pipes of the drainage system. This system also carries away solid waste from sinks, toilets, garbage disposers, and other fixtures and appliances. The pipes of the drainage system are larger than the pipes of the water supply system in order to prevent them from becoming clogged with solid materials.



The drainpipes from the fixtures and appliances slar downward, carrying water and sewage to a vertical pi called the *soil stack.* The soil stack empties into a main drain beneath the building. This drain leads to a sewer or septic tank outside the building. The top of the soil stack extends up through the roof of the building, whe air enters the opening, or *vent,* in this pipe. The air flov through the soil stack into a network of *revent pipes.* The revent pipes lead into the drainpipes of the fixture that are not near the soil stack. Most toilets are close tc the soil stack, and so their drainpipes are connected di rectly to it.

The flow of air into the drainage system prevents a partial vacuum from developing in the pipes as water and sewage flow out. Such a vacuum would slow the passage of water and sewage from the drainage systen In some plumbing systems, the revent pipes extend through the roof of the building instead of leading to the soil stack.

The soil stack and revent pipes also perform another important function. The drainpipe of each plumbing fix ture and appliance empties through a U- or S-shaped bend that is called a *trap.* Water is held in the trap whe ever the fixture or appliance is not being used. The water in the trap serves as a seal that prevents harmful gases from the sewer or septic tank from entering the building through the fixtures or appliances. Instead, the

A home plumbing system All plumbing systems have a water supply system and a drainage system. The water supply system brings clean water to plumbing fixtures and appliances. The drainage system has drainage pipes that carry away water and waste materials. Venting pipes keep air flowing through the system.

WORLD BOOK diagrams by Steven Li

An air chamber, *above,* con nects to pipes that lead to fix tures or appliances. A cushio of air inside the chamber ab- sorbs the force of incoming water after a faucet or valve i closed quickly. Without an ai chamber, the pipes would vi brate and make a hammering noise just after the water is shut off.

ises escape through the soil stack and revent pipes.
Many traps have a *cleanout plug* that can be removed the pipe becomes clogged. A long, flexible tool called *drain auger,* or *snake,* can then be inserted into the pe to clear it. Cleanout plugs are also located at other oints throughout a drainage system. Almost all plumbg systems have a cleanout plug where the soil stack onnects to the main drain of the building.

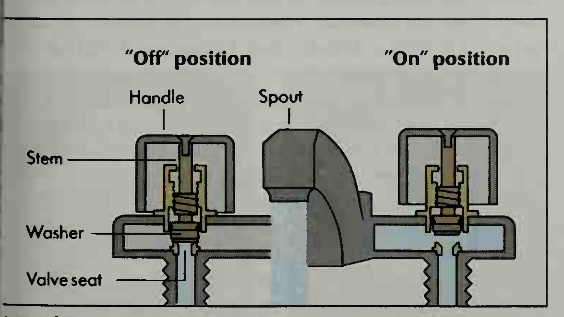
In many communities, sewage flows from the main rain of each building into an underground system of pes that carries it to a *sewage treatment plant.* The ant treats the sewage water and reduces the bacteria it. The water can then be poured into a river or other ody of water with minimum damage to the waterway.

Many rural and suburban areas do not have a public ewerage system. There, the sewage from a building ows into a septic tank nearby. Bacteria in the septic nk break down most of the solids in the sewage into as and a harmless substance called *humus.* The gas escapes into the air, and the humus is removed periodially. The liquids run out of the tank into the surroundig soil. See **Sewage**.

How faucets work. The flow of water is regulated by ucets in bathtubs, showers, sinks, and other principal inds of plumbing fixtures except toilets. Faucets are lso called *taps.*

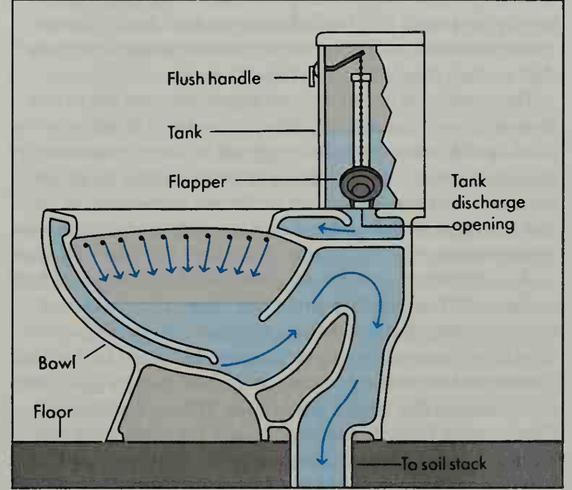
There are two main kinds of faucets, *washer-type faucets* and *washerless faucets.* Most washer-type faucets ave two handles, one for hot water and one for cold. he water comes out of a single spout. Older washerype faucets have a separate handle and spout for hot nd cold water.

In a washer-type faucet, water is turned on and off by urning one or both of the handles. A threaded *stem* is ttached to each handle and screws into the faucet. At he bottom of each stem is a washer made of rubber or f synthetic fibers. When the faucet is turned off, the tem and washer are held tightly over a *valve seat* at the op of the water supply pipe. The washer prevents the low of water into the faucet. When the faucet is turned n, the stem is unscrewed enough to lift it and the vasher off the seat. Water can then flow into and hrough the spout.



Washerless faucets have either two handles or one, nd most have a single spout. In a washerless faucet vith two handles, water is turned on and off the same way as in washer-type faucets. In most single-handle washerless faucets, water is turned on by lifting the handle and is turned off by pressing the handle down. The temperature of the water is regulated either by turning the handle or by moving it from side to side.

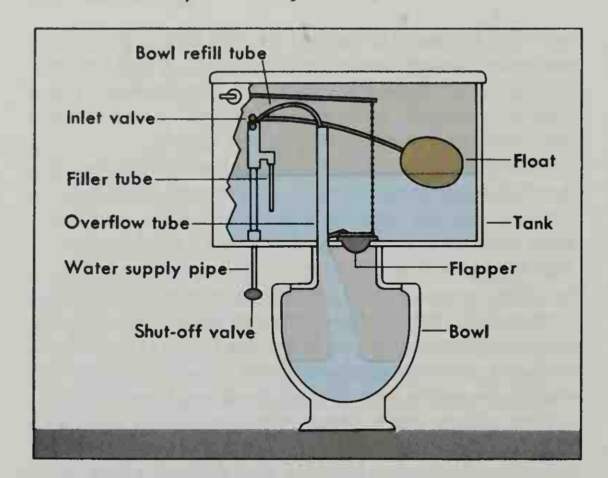
Attached to the handle of a typical washerless faucet is a disk or some other device with several holes in it. This disk fits over another disk. The two disks have the same number of holes, and all the holes are the same size. When the faucet is turned off, the position of the top disk changes so that the disk covers the holes of the bottom disk. Water cannot flow into the faucet when the top disk is in this position. When the faucet is turned on, the holes of the two disks are lined up with one another, enabling water to flow through them and into the spout.

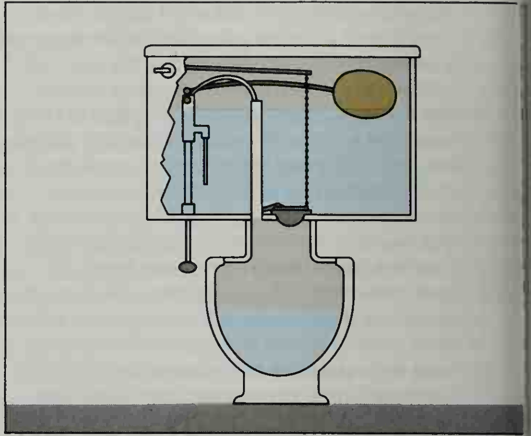


How toilets work. Most toilets consist of a *bowl* and a *tank,* both of which contain water. When a toilet is flushed, water rushes from the tank through a *tank discharge opening* and into the bowl. The rushing water carries the contents of the bowl through the trap of the toilet to the soil stack. The bowl and tank refill with water from a water supply pipe, and the toilet is ready to be flushed again.

When the tank of the toilet is full, a *stopper ball* or a *flapper* covers the tank discharge pipe. The ball or flapper prevents water from running out of the tank before the toilet is flushed. To prevent more water from entering the tank, an *inlet valve* covers the opening of the water supply pipe. Attached to the inlet valve is a device called a *float.* The float rides on the water.

When a toilet is flushed, the action of pushing down the handle lifts the stopper ball or flapper from the tank discharge opening. The ball or flapper floats on the water rushing through the opening in the pipe. As the level of the water goes down, so does the level of the float. The lowering of the float opens the inlet valve, and more water enters the tank through a *filler tube.* But water continues to flow from the tank until the level falls below the tank discharge opening. The stopper ball or





A washer-type faucet has a threaded *stem* attached to each of its handles. At the bottom of each stem is a washer. When the water is turned off, the stem and washer are held tightly over a *valve seat* at the top of the water supply pipe. When the water is turned on, the stem and washer are held off the seat.

WORLD BOOK diagrams by Steven Liska

Flushing a toilet lifts a *flapper* off the *tank discharge opening,* enabling water to rush into the *bowl.* The water carries the bowl's contents into the drainpipe and to the soil stack. When the tank is nearly empty, the flapper drops down.

WORLD BOOK diagrams by Steven I

A toilet refills after the water has run out of the tank. The *float* lowers with the water, opening the *inlet valve* over the water supply pipe. Water then enters the tank through a *filler tube.* Water also goes into a *bowl refill tube* and enters the bowl through an *overflow tube.* The float rises with the level of the water in the tank, *above left.* When the tank and bowl are full, the float causes the inlet valve to close over the water supply pipe, *above right,* and stop the flow of water.

flapper then drops onto the tank discharge opening, and water from the filler tube refills the tank.

Some of the water from the filler tube goes into a *bowl refill tube.* It then flows into an *overflow tube* and washes down the sides of the toilet bowl. As the level of water in the tank rises, so does the level of the float. The float rises until the water is about an inch (2.5 centimeters) from the top of the overflow tube. Both the tank and the bowl have now been refilled. The inlet valve closes over the opening of the water supply pipe, and the water is shut off.

History. The earliest plumbing systems disposed of human wastes. In the Indus Valley in what are now Pakistan and western India, most dwellings had drains for waste disposal by about 2500 B.C. A palace built on the island of Crete about 2000 B.C. had pipes that supplied drinking water. It also had primitive toilets and a drainage system with air shafts that served as vents. The ancient Romans developed faucets and a sewerage system that carried waste into rivers and streams.

The quality of plumbing declined after the fall of the Roman Empire in western Europe in the A.D. 400's. In the Middle Ages, people disposed of waste materials by throwing them into the street. A type of flush toilet was developed in the 1500's. But it did not come into wide use because of the general lack of plumbing and sewerage systems. In 1778, Joseph Bramah, an English cabinetmaker, patented an improved flush toilet. In the first half of the 1800's, toilets became common in England. But most of them drained into pits called *cesspools,* which often overflowed. Septic tanks were invented in the mid-1800's, and a modern sewerage system began operating in London in the 1860's. Also in the 1860's, Sir Thomas Crapper, an English plumber, made improvements in the flush toilet patented by Bramah. Evan Powell

Plutarch, *PLOO tahrk* (A.D. 46? - A.D. 120?), a Greek biographer and essayist, became famous for his work, *Parallel Lives of Illustrious Greeks and Romans.* Plutarch wrote these biographies in pairs, each comparing one Greek and one Roman statesman or general. The comparisons are often forced, but the *Lives* constitute an important source of historical information. Twenty-three pairs of the *Lives* have survived.

Plutarch's Lives became the basis of many stories and poems of the Middle Ages. William Shakespeare and other Elizabethan dramatists used a brilliant translation of the *Lives* by Sir Thomas North for material for many of their historical plays. The *Lives* contains sharply drawn character sketches and lively historical descriptions of Greece and Rome.

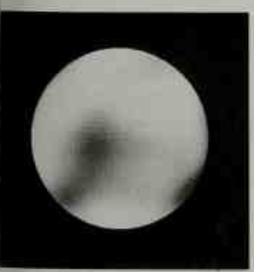
Plutarch also wrote essays and dialogues on historical, rhetorical, and philosophical topics collected under the title *Morals.* Among them is a curious account of *The Face on the Moon.*

Plutarch was born at Chaeronea, in Boeotia, Greece, near the homes of Hesiod and Pindar. He studied philosophy in Athens and later lectured on this subject in Rome. In travels through Greece, Italy, and Egypt, he spent much time studying and collecting facts on the men of whom he wrote. He returned to Boeotia as a priest of Apollo at Delphi, and it is believed that he wrote his great works there. Cynthia W. Shelmerdine

Pluto, *PLOO toh,* is the most distant planet from the sun. Pluto and Neptune are the only planets that cannot be seen without a telescope. Astronomers "discovered" both these planets by using mathematics.

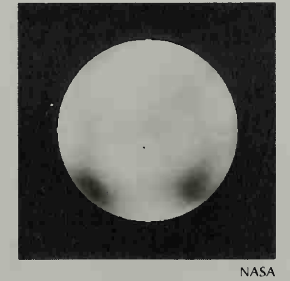
Pluto is about 39 times as far from the sun as Earth is. Its mean distance from the sun is about 3,666,200,000 miles (5,900,100,000 kilometers). Pluto travels around the sun in an *elliptical* (oval-shaped) orbit. At some point in its orbit, it comes closer to the sun than Neptune, usually the second farthest planet. It stays inside Neptune's orbit for about 20 earth-years. This event occurs every 248 earth-years, which is about the same number of earth-years it takes Pluto to travel once around the sun.

uto at a glance



istance from the sun: *Shortest*—2,749,600,000 mi. 425,100,000 km); *Greatest*—4,582,700,000 mi. (7,375,100,000 km); *lean*—3,666,200,000 mi. (5,900,100,000 km).
istance from the earth: *Shortest*—2,670,000,000 miles 290,000,000 kilometers); *Greatest*—4,670,000,000 miles 520,000,000 kilometers).
iameter: 1,430 miles (2,300 kilometers).
ength of year: About 248 earth-years.
otation period: About 6 earth-days.
emperature: About −390 to −370 °F (−230 to −220 °C).
tmosphere: Methane.
atellites: 1.

uto last entered Neptune's orbit on Jan. 23, 1979, and emained there until Feb. 11, 1999. As it orbits the sun, uto spins on its axis, an imaginary line through its cen-er. It spins around once in about six earth-days.



Astronomers know little about Pluto's size or surface onditions because it is so far from Earth. Pluto has an stimated diameter of about 1,430 miles (2,300 kilome-ers), less than a fifth that of Earth. Pluto's surface is one f the coldest places in our solar system. Astronomers elieve the temperature on Pluto may be about −390 to −370 °F (−230 to −220 °C). The planet appears to be artly covered with frozen methane gas and to have a hin atmosphere composed mostly of methane. Because luto's density is low, astronomers think Pluto is mainly cy. Scientists doubt Pluto has any form of life.

Many astronomers do not consider Pluto to be a plan-t. They have two reasons for their belief: (1) Pluto does ot resemble any of the four planets that are closest to t—Neptune, Uranus, Saturn, and Jupiter. Pluto is small nd icy, and the other four are huge and gaseous. (2) Plu-o resembles *Kuiper belt objects* (KBO's), bodies that ave been discovered beyond Pluto's orbit. All the KBO's ever found are smaller than Pluto, so the astronomers onsider Pluto to be merely the largest known KBO.

In 1905, Percival Lowell, an American astronomer, ound that the force of gravity of some unknown planet eemed to be affecting the orbits of Neptune and Ura-nus. In 1915, he predicted the location of a new planet nd began searching for it from his observatory in Flag-staff, Arizona. He used a telescope to photograph the rea of the sky where he thought the planet would be ound. He died in 1916 without finding it. In 1929, Clyde W. Tombaugh, an assistant at the Lowell Observatory, used predictions made by Lowell and other astrono-mers and photographed the sky with a more powerful, wide-angle telescope. In 1930, Tombaugh found Pluto's image on three photographs. The planet was named after the Roman god of the dead. The name also honors Percival Lowell, whose initials are the first two letters of *Pluto*. In 1978, astronomers at the U.S. Naval Observatory substation in Flagstaff detected a satellite of Pluto. They named it Charon. This satellite has a diameter of 737 miles (1,186 kilometers).

NASA

NASA

Pluto is so far from Earth that even powerful telescopes reveal little detail of its surface. The Hubble Space Telescope gathered the light for these pictures of Pluto.

In 1996, astronomers published the first detailed im-ages of Pluto's surface. The images, taken by the Hubble Space Telescope, show about 12 large bright or dark areas. The bright regions, which include polar caps, are probably frozen nitrogen. The dark areas may be meth-ane frost that has been broken down chemically by ul-traviolet radiation from the sun. Hyron Spinrad

See also **Lowell, Percival; Planet; Solar system.**

Pluto, *PLOO toh,* was the god of the dead in Roman mythology. The Romans sometimes called him *Dis Pater* or *Orcus*. Pluto was almost identical to Hades, the Greek god of the dead. The Romans borrowed and preserved without change almost all the myths about Hades and his underworld kingdom. Some scholars believe the Ro-mans had no god of the dead before they came into contact with Greek culture in the 700's B.C. The name *Pluto* comes from *Pluton,* an alternate Greek name for Hades. See also **Hades; Persephone.** Daniel P. Harmon

Plutonium, *ploo TOH nee uhm,* is a radioactive metal-lic element. Almost all plutonium is produced artificially. Only an extremely small amount of it occurs naturally. Plutonium has a variety of scientific and industrial uses. Its chemical symbol is Pu, and its atomic number is 94 (see **Atom** [The atomic number]). Plutonium melts at 640 °C and boils at 3460 °C. At 20 °C, it has a density of 19.86 grams per cubic centimeter (see **Density**).

Plutonium is highly poisonous because it rapidly gives off radiation in the form of high-energy alpha par-ticles (see **Alpha particle**). These particles may cause cancer or other serious health problems. In addition, plutonium is extremely explosive. It must be kept in quantities smaller than a *critical mass,* the amount at which it would explode spontaneously.

Scientists have discovered 15 isotopes of plutonium. These isotopes have mass numbers 232 through 246. The most important isotope is Pu-239, which readily un-dergoes *fission* when struck by a neutron. In fission, the nucleus of an atom is split into two nearly equal parts, and energy is released. Pu-239 is a source of energy in nuclear reactors and nuclear weapons. Scientists pro-duce Pu-239 by bombarding uranium 238 with neutrons. The same process forms Pu-239 as a waste product in nuclear reactors that use uranium as the basic fuel. The disposal of waste Pu-239 has become a serious problem because of its relatively long *half-life* of 24,100 years.

Plutonium has various other applications. For exam-ple, Pu-238 powers heart pacemakers, certain instru-ments on spacecraft, and some other devices. Pu-242 and Pu-244 are useful in studying chemicals and metals.

Plutonium was discovered in 1940 by four American scientists—Glenn T. Seaborg, Edwin M. McMillan, Joseph W. Kennedy, and Arthur C. Wahl. They produced Pu-238 by bombarding uranium 238 with *deuterons,* the nuclei in atoms of *deuterium,* an isotope of hydrogen. The most stable plutonium isotope, Pu-244, was discov-ered in nature in 1971. J. Rayford Nix

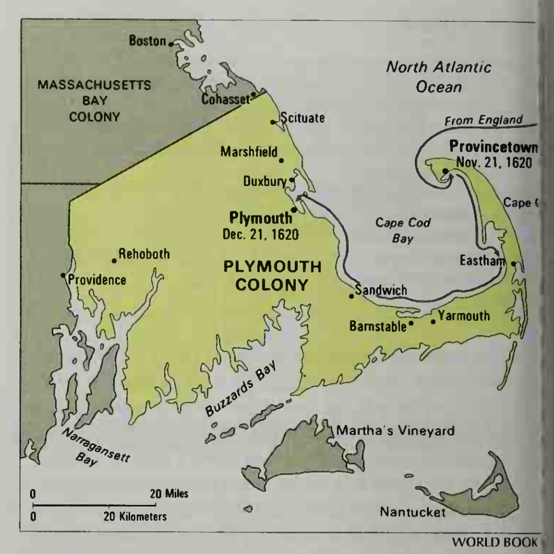
Plymouth, *PLIHM uhth,* is a historic seaport on the southwest coast of England. It is the chief city in the district of Plymouth, which has a population of about 253,400. The city lies on Plymouth Sound, an inlet of the English Channel and one of the world's finest natural harbors (see **England** [political map]).

The site of a naval dockyard, Plymouth was the target of German bombing raids during World War II (1939-1945). Much of the center of the city was destroyed by the raids. The center has since been rebuilt in a modern style. Parts of Plymouth escaped serious damage and have buildings that are hundreds of years old. The city's chief industries include engineering and the manufacture of clothing and electronic goods.

In the late 1500's, Sir Francis Drake and other English explorers set sail from Plymouth. The *Mayflower,* the ship that carried the Pilgrims to North America in 1620, also sailed from Plymouth. Peter R. Mounfield

Plymouth, *PLIHM uhth,* Massachusetts (pop. 51,701), is often called *America's Hometown.* In 1620, colonists from England sailed across the Atlantic on the *Mayflower* and settled in Plymouth. Plymouth was the second permanent English settlement in America. Jamestown, Virginia, was the first. Plymouth lies on a harbor, about 40 miles (64 kilometers) south of Boston (see **Massachusetts** [political map]). Plymouth Rock lies near the spot where the colonists are believed to have landed (see **Plymouth Rock**). Plimoth Plantation, a re-creation of the original settlement, features *Mayflower II,* built the way the original *Mayflower* is believed to have looked (see **Mayflower** [picture: *The Mayflower II*]). Many tourists visit Plymouth, and the town's economy is based on tourism. The processing of cranberries is also an important economic activity in the area. The Pilgrim 1 nuclear power plant is located in Plymouth. Laurence A. Lewis



Plymouth Colony, *PLIHM uhth,* was the second permanent English settlement in America. The colonists who settled there became known as *Pilgrims* because of their wanderings in search of religious freedom. In 1620, they established their colony on the rocky western shore of Cape Cod Bay in southeastern Massachusetts. This region had been called *Plimouth* on John Smith's map of New England, drawn in 1614. The Pilgrims established the Congregational Church in America. Plymouth Colony remained independent until 1691, when it became part of Massachusetts Bay Colony.

Plymouth Colony and the Pilgrims have become for all Americans a lesson of how a people with little more than courage, perseverance, and hard work could build themselves a home in a hostile world. Their bravery set an example for future generations of Americans.

Many tourists visit modern Plymouth with its memorials to the Pilgrim forefathers. Just south of town there is a model of the original Pilgrim village. Plimoth Plantation, Inc., a nonprofit organization dedicated to the preservation of the Pilgrim heritage, also maintains a replica of the first Pilgrim house and of the *Mayflower.*

The founding of Plymouth Colony

Most of the Pilgrims were *Separatists* (Puritans who had separated from the Church of England). The government of England arrested and tried the Separatists because of their *nonconformity* (refusal to belong to the Church of England). In 1608, a group of Separatists

Plymouth Colony was founded in 1620 by Pilgrims who saile from England aboard the *Mayflower.* They first landed at Provincetown and later sailed around Cape Cod Bay to Plymouth. This map shows the extent of Plymouth Colony in 1630.

moved to the Netherlands. After a few years, some of them became dissatisfied, and felt that things would b better in a new land. They secured financial backing in London, and, in 1620, left the Netherlands in a small sh called the *Speedwell.* The ship stopped in England, an the expedition was joined by other English people wh hoped to better their lives. The group left England in th *Speedwell* and a larger ship, the *Mayflower.* The *Spee well* proved unseaworthy, and the fleet returned to En land twice. Finally, in September 1620, the *Mayflower* sailed alone from Plymouth, England. It carried 102 pas sengers, including women and children.

A rough passage of 65 days brought the *Mayflower* Cape Cod on November 20 (November 10, according t the calendar then in use). The Pilgrims had promised to settle somewhere within the limits of the original grant of the Virginia Company of Plymouth (see **Plymouth Company**). But errors in navigation led them to the Ne England region. Adverse winds and the shoals off Cape Cod forced the *Mayflower* to stay north. The ship anchored in Provincetown harbor inside the tip of Cape Cod on November 21.

The Pilgrim leaders were uncertain of their legal pos tion because they were in the area without authority. They also knew they would need discipline among themselves. To solve these problems, 41 men aboard the *Mayflower* met and signed the Mayflower Compac in which they agreed to form a government and to obe its "just and equal laws." The Pilgrims also elected John Carver as their governor.

The landing at Plymouth. The sea-weary Pilgrims were anxious to learn more about the country. For almost a month, several small groups explored the coast around Cape Cod Bay while the rest remained aboard. One of the groups had to take refuge on an island in Plymouth harbor during a blinding snowstorm. On Dec 21, 1620, this group landed at Plymouth. There they found a stream with clear water, some cleared land, an

ıigh hill that could be fortified. This site was once an dian village, but smallpox had wiped out all the Indi- ıs in 1617. The Pilgrims decided that this would be eir new home. The *Mayflower* sailed across Cape Cod ıy and anchored in Plymouth harbor on December 26.

The first year was a difficult one for the Pilgrims. ıor and inadequate food, strenuous work, and change- ıle weather made the settlers susceptible to sickness. ıe colony lost about half its members that first winter.

But help came one spring morning, when an Indian alked into the little village and introduced himself to e startled people as Samoset. He later returned with ıuanto. They introduced the Pilgrims to Massasoit, the *chem* (chief) of the Wampanoag tribe that controlled l southeastern Massachusetts. Carver and the chief ex- ıanged gifts and arranged a treaty of peace. Soon af- rward, the *Mayflower* sailed for England, leaving the lgrims. Then Carver died, and William Bradford be- ıme governor of the colony.

The Pilgrims, under Squanto's direction, caught *ale- ives* (a fish in the herring family) and used them as fer- lizer in planting corn, pumpkins, and beans. They unted and fished for food. The harvest that year led overnor Bradford to declare a celebration. Sometime ı the autumn of 1621, the Pilgrims invited their Indian iends to join them in a three-day festival that we now all the first New England Thanksgiving. The menu in- luded corn bread, duck, eel, goose, wild leeks, shell- sh, venison, watercress, and wine.

Life in Plymouth Colony

The Pilgrims received legal rights to settle at Plym- uth under a patent granted by the Council for New ngland in 1621. Governor Bradford received a new pat- nt, the Warwick Patent, in 1630. It granted him all the ınd south of a line between Narragansett Bay and Co- ıasset. Under this patent, Bradford could have claimed ıwnership of the entire colony, but he shared control with the other settlers. He turned the patent over to all the *freemen* (voters) of the colony in 1640. A few years later, surveyors marked off an area corresponding to the present counties of Bristol, Barnstable, and Plymouth as the colony of Plymouth.

Expansion of the colony. In November 1621, the ship *Fortune* arrived with 35 new colonists. Other ships brought additional settlers but the population grew to only 300 settlers in 10 years. Some of the colonists decided to move from Plymouth to better lands. Some went north and established the towns of Duxbury, Marshfield, and Scituate. Others moved west to Rehoboth, or farther east on Cape Cod to settle Sandwich, Barnstable, Yarmouth, and Eastham.

Government. The men who signed the Mayflower Compact were the freemen of the colony. They, along with any newly chosen freemen, met once a year to discuss the problems of the colony. This body, called the General Court, elected the governor and his assistants, made laws, and levied taxes. In outlying towns, the freemen held town meetings to elect their own officers and settle town matters. Beginning in 1639, these towns sent representatives to the General Court at Plymouth.

Economic life. The Pilgrims organized a joint-stock company with some London merchants to finance the voyage. The partnership was to last for seven years. The Pilgrims agreed to put the results of their labor into a common fund, which would provide the necessities of life for the settlers. At the end of seven years, all the profits and property were to be divided among the financiers and the settlers. This experiment did not work out, and in 1623 the colony allowed settlers to farm individual plots. The London merchants in 1627 agreed to sell their interest in the company to the Pilgrims, who finished paying off the debt in 1648.

The Pilgrims at first expected to make a profit from fishing. But they were never very successful at this. They turned to farming for their existence and to fur trading

An oil painting on canvas (about 1919); Smithsonian Institution, Washington, D.C. (Archives of 76, Bay Village, Ohio © J. L. G. Ferris)

A Thanksgiving feast was celebrated by the Pilgrims in 1621. They invited Indians who had helped them grow a plentiful harvest. The event is shown at the left in a painting by the American artist Jean Leon Gerome Ferris.

for profit. When other Puritans settled Massachusetts Bay Colony in 1628, the Pilgrims developed a prosperous trade in corn and cattle with them. Through steady and hard work, the colony was able to live moderately well without extremes of wealth or poverty.

The honored ones. William Bradford, the second governor of Plymouth, wrote a history of the Pilgrims' adventure aboard the *Mayflower.* He listed the ship's passengers as follows:

> Mr. John Carver; Kathrine, his wife; Desire Minter; & 2. man-servants, John Howland, Roger Wilder; William Latham, a boy; & a maid servant, & a child yt was put to him, called Jasper More.
>
> Mr. William Brewster; Mary, his wife; with 2. sons, whose names were Love & Wrasling; and a boy was put to him called Richard More; and another of his brothers. The rest of his childeren were left behind, & came over afterwards.
>
> Mr. Edward Winslow; Elizabeth, his wife; & 2. men servants, caled Georg Sowle and Elias Story; also a litle girle was put to him, caled Ellen, the sister of Richard More.
>
> William Bradford, and Dorothy, his wife; having but one child, a sone, left behind, who came afterward.
>
> Mr. Isaack Allerton, and Mary, his wife; with 3. children, Bartholmew, Remember, & Mary; and a servant boy, John Hooke.
>
> Mr. Samuell Fuller, and a servant, caled William Butten. His wife was [left] behind, & a child, which came afterwards.
>

> John Allerton and Thomas Enlish were both hired, the later to goe mr [master] of a shalop here, and ye other was reputed as one of ye company, but was to go back (being a seaman) for the help of others behind. But they both dyed here, before the shipe returned.
>
> Ther were allso other 2. seamen hired to stay a year he in the country, William Trevore, and one Ely. But when th time was out, they both returned.
>
> These, bening aboute a hundred sowls, came over in t first ship; and began this worke, which God of his goodn hath hithertoo blesed; let his holy name have ye praise.

Although 102 Pilgrims sailed from England, one die and another was born during the voyage. So 102 reached the harbor at Provincetown, Mass. Four more died and one was born there. The group that landed a Plymouth consisted of 99 Pilgrims.

Later years. The Massachusetts Bay Colony's superior harbor at Boston helped draw trade and settlers from Plymouth Colony. Boundary and trade disputes increased among the colonies that had formed in the are The Pilgrims also faced the danger of attack by nearby Indians and Dutch and French colonists. In 1643, Plymouth Colony joined the Massachusetts Bay, Connecticu and New Haven colonies in forming the New England Confederation. This alliance worked to settle disputes and provide for the common defense.

A long tradition of peace between the Pilgrims and the Wampanoag Indians ended in 1675. That year, Metcomet, the son of Massasoit, led an Indian war against the colonies in New England. The colonists called Metcomet King Philip, and the war became known as King Philip's War (see **Philip, King**). The Indians attacked because they feared that the colonists would take all their land. Metacomet was killed in 1676, and the war in southern New England then ended. Fighting in norther New England continued until 1678. In 1686, King James of England tried to reassert control over the colonies b combining Plymouth and the rest of New England, New York, and New Jersey into the Dominion of New England. However, the dominion proved unpopular and was disbanded in 1689. In 1691, Plymouth became part of Massachusetts Bay Colony.

Plymouth Company, *PLIHM uhth,* was one of two associations chartered in 1606 by King James I for English merchants and other interested people who wanted to set up trading colonies in America. Its full title was the Virginia Company of Plymouth. The other association was the Virginia Company of London, or the London Company (see **London Company**). The charter gave the Plymouth Company permission to establish a colony in North America between the parallels of 38° and 45° north latitude. The London Company had permission to colonize between 34° and 41° north latitude.

In 1607, explorers for the Plymouth Company founded a colony at the mouth of what is now the Kennebec River on the coast of Maine. The colony failed after one winter. The company then showed only occasional interest in its territory. After 1614, it sponsored explorations

/ Captain John Smith to what is now the New England ·gion. Smith named the area *New England,* mapped its ›ast, and publicized its attractions. See **Smith, John.**

In 1620, a group of investors led by Sir Ferdinando orges, reorganized the company and renamed it the ouncil for New England. Gorges, a leader from the ymouth Company's early expeditions to America, won new royal charter. This charter gave the council con- ol of land between 40° and 48° north latitude and rights ›r fishing off the territory's shores. Settlers from Eng- nd who became known as the Pilgrims established ymouth Colony there in 1620. In 1621, the council ranted the Pilgrims the legal right to settle in its area ee **Plymouth Colony**). The Council for New England /as disbanded in 1637. Pauline Maier

ılly stepped on the rock. It is more likely that the rock vas near the spot where the Pilgrims landed. The rock vas moved several times between 1774 and 1921. Today, it stands under a granite canopy near the water's ;dge, where it serves as a memorial to the landing of he Pilgrims in 1620. Joan R. Gundersen

Plywood is a building material usually made of an odd ıumber of thin layers of wood glued together. The lay- ɜrs, called *plies* or *veneers,* are arranged so that the *grain direction* (direction of the wood fibers) of each ayer is at right angles to that of the layer next to it. The outside plies are called *faces* and *backs,* and the center ply or plies are called the *core.*

The simplest plywood is made of three plies of ve- neer. However, five, seven, nine, or more plies may be used. In some cases, plywood may have an even num- ber of plies, with the grain direction of the two center plies being parallel. The term *plywood* is also used for door panels that have a solid lumber core up to 3 inches (7.6 centimeters) thick.

Kinds of plywood. Plywood is classified in two ways—by material and by use. Most *softwood* plywood is made of Douglas-fir or southern pine. Western hem- lock, white fir, ponderosa pine, redwood, and many other trees are also used. *Hardwood* plywood is avail- able in over 80 kinds of wood. They include domestic woods such as oak, red gum, poplar, birch, cherry, and walnut. Imported woods used in plywood include ma- hogany and other attractive tropical woods.

American Plywood Assn.

Plywood consists of several *plies* (layers) of wood glued to- gether. It is stronger than ordinary wood and is used chiefly for floors, to line roofs and walls, and for wall paneling.

Interior plywood is usually made with glues that are moisture-resistant. *Exterior* plywood is designed to with- stand severe conditions resulting from moisture and hu- midity. It is always made with waterproof glues.

The most commonly available types of plywood pan- els are 4 feet (1.2 meters) wide, 8 feet (2.4 meters) long, and from $\frac{1}{4}$ to $\frac{3}{4}$ inch (6 to 19 millimeters) thick. Dimen- sions of plywood panels usually range from 3 to 5 feet (0.9 to 1.5 meters) wide, 5 to 12 feet (1.5 to 3.7 meters) long, and $\frac{3}{16}$ to $1\frac{3}{16}$ inches (5 to 30 millimeters) thick. Three, five, or seven plies are normally used.

Use of plywood. Plywood's main advantages over or- dinary lumber are that it is lightweight and workable, yet rigid and strong. Plywood can also be cut to exact sizes and produced in large panels for ease of applica- tion, strength, and smooth surfaces. It shrinks and swells less than ordinary wood and has greater resistance to splitting at the ends. This permits carpenters to fasten plywood sheets with nails or screws close to the edges. Plywood also has little tendency to warp or twist. Deco- rative hardwood veneers can provide the look of expen- sive woods without the cost because only thin sheets are needed. Plastic or metal faces are sometimes used to provide surfaces that resist scratching. Plywood can also be made in curved shapes.

Softwood plywood is used chiefly as a structure upon which finished walls, flooring, and roofing are laid. It is also particularly suited for the forms used in shaping concrete for building, bridge, and dam foundations. Carpenters and cabinetmakers find wide use for hard-

wood plywood in furniture, cabinets, counters, and decorative wall paneling. Manufacturers use both hardwood and softwood in boats, recreational vehicles, office equipment, railroad cars, road signs, sporting goods, and other products.

Making plywood is done in three steps. They involve (1) the log, (2) the veneer, and (3) the lay-up.

Logs used for plywood are selected for straightness, roundness, and freedom from knots and decay. After the bark is removed and the logs cut to the desired lengths, they are often steam-heated. This softens their surfaces, and they are placed into the lathe or slicer to be converted to veneer.

Veneer is made in one of three ways. These are (1) sawing, (2) slicing, or (3) rotary cutting. *Sawing* is used only for fine finishing woods, such as ebony or knotty pine, which are too brittle or unsuitable for slicing. *Slicing* is used chiefly for fine-figured woods for furniture or wall-panel faces. Slicing is done by moving the log, called a *flitch,* against a heavy, stationary knife.

About nine-tenths of veneer is *rotary cut* with a lathe. The log is placed in a lathe and then revolved against a stationary knife extending across its length. The veneer is then unwound in a long, continuous ribbon.

The lay-up takes place after the plies are dried, trimmed, and matched. A thin layer of glue is applied to each ply. Workers then *lay-up,* or place, the plies with the grain in each ply opposite to that in the adjacent ply. Hydraulic presses squeeze the plies together with heat and pressure, or pressure only. Then the finished plywood is again dried, trimmed, sanded, or otherwise finished into sheets. Lewis T. Hendricks

Pneumatic tool, *noo MAT ihk,* is a power implement operated by compressed air. Pneumatic tools have various uses. For example, dentists use air-powered drills to remove tooth decay. Automobile mechanics use pneumatic wrenches to tighten nuts and bolts. Construction workers use pneumatic hammers to break up pavement. In addition, the gas turbines in jet engines and the air brakes in heavy trucks and railroad trains are operated by compressed air.

The air for pneumatic tools is supplied by a machine called an *air compressor.* The compressor squeezes together air molecules, usually to a pressure of about 100 pounds per square inch (690 kilopascals). The air drives the tool in either a *reciprocating* (back and forth) motion or a *rotary* (circular) motion.

Reciprocating motion is used in jackhammers, riveting tools, ramming tools, and digging tools. In these tools, compressed air causes a piston to move back and forth inside a cylinder. The piston then pushes against a striking device at the end of the tool. A small jackhammer can deliver from 2,000 to 3,000 blows per minute. In an air brake, the piston applies or releases the brake after receiving a signal from the driver to do so (see **Brake** [Air brakes]).

Rotary motion is used in power drills, power wrenches, grinders, and sanders. Such tools have a rotating part called a *rotor,* which has several blades. The rotor spins as compressed air is forced against each blade in turn. As the rotor spins, it turns a shaft that is connected to a device for drilling, grinding, or other rotary action. Thousands of rotations may occur per minute. The high speed of the rotations causes the high-pitched noise that comes from a dentist's drill, the turbines in a jet engine, and other rotating pneumatic machinery. Richard M. H. Cheng

Pneumoconiosis. See **Black lung.**

Pneumonia, *noo MOHN yuh,* is a general term for lung diseases involving inflammation. Most cases of pneumonia result from infection, usually by viruses or bacteria, but sometimes by fungi or other microbes. A few cases are caused by allergic reactions or by inhaling irritating chemicals.

Before the development of antibiotic drugs during the 1940's, pneumonia killed about a third of its victims. Today, with appropriate treatment, most pneumonia patients recover. But pneumonia still ranks as one of the leading causes of death in the United States. About 50,000 Americans die of the disease each year.

People with other serious health problems have the greatest risk of getting pneumonia. They also have the most difficulty recovering from it. These individuals include heavy smokers; alcoholics; people with diabetes, cancer, or kidney disease; and people with conditions that weaken the body's resistance to infection. Pneumonia is one of the illnesses most commonly associated with AIDS (acquired immunodeficiency syndrome), a disease that severely weakens the body's immune system. Children and elderly people also have a greater than average risk of developing pneumonia.

How pneumonia develops. In some cases, a person gets pneumonia by inhaling small droplets that contain potentially harmful viruses or bacteria. These droplets are sprayed into the air when an infected person coughs or sneezes. In most other cases, pneumonia results when bacteria normally present in the nose, mouth, or throat invade the lungs. The body's defense mechanisms ordinarily prevent these bacteria from reaching the lungs. But if the body's defense mechanisms are weakened or are already fighting other diseases, pneumonia may develop. Such an infection is called *opportunistic.* Patients hospitalized for other diseases may develop pneumonia from opportunistic microbes or exposure to infectious agents from other patients.

In the lungs, the microbes that cause pneumonia can lodge in the air sacs, where the oxygen is normally exchanged for carbon dioxide in the blood. There, the microbes can multiply rapidly and the air sacs may fill with fluid and with white blood cells produced by the body to fight the infection. When a *lobe* (major section) of a lung is affected, the infection is called *lobar pneumonia.* The infection is called *bronchial pneumonia* if it primarily affects the *bronchioles* (tiny air passages of a lung). *Interstitial pneumonia* chiefly affects the *interstitium,* which are the small spaces between the air sacs and the blood vessels.

Many kinds of viruses can cause pneumonia, including the same ones that cause influenza and other respiratory infections. The most common bacterial causes of pneumonia include *Streptococcus pneumoniae,* also called *pneumococci; Staphylococcus aureus; Haemophilus influenzae;* and *Mycoplasma pneumoniae,* a bacterialike organism that frequently causes pneumonia in children and young adults. Pneumonia associated with Legionnaires' disease is caused by the bacteria

gionella pneumophila or *Legionella micdadei.* A pro-
zoan called *Pneumocystis carinii* frequently causes
eumonia in patients with weakened immune systems,
ch as people with AIDS.

Symptoms and diagnosis. The symptoms of pneu-
onia vary with the type of microbe involved and the
tient's general health before the onset of the disease.
general, the symptoms of bacterial pneumonia are
ore severe than those of viral pneumonia. Most cases
bacterial pneumonia start with a sudden attack of
ills, high fever, and chest pain. The patient also may
velop a painful cough, which is dry at first but later
oduces rust-colored *sputum* (mucus and other sub-
ances from the lungs). Most cases of viral pneumonia
e mild. Symptoms include fever, weakness, cough,
d production of sputum.

Using a stethoscope, a physician can hear characteris-
 sounds from the lungs that indicate the presence of
eumonia. X rays and laboratory tests confirm the diag-
sis. To determine the type of bacteria involved, the
ctor examines the patient's sputum under a micro-
ope. Sputum samples are treated with chemicals and
ains to make the infecting bacteria visible with a mi-
oscope. Other sputum samples are used to *culture*
ow) the infecting organisms in laboratory dishes or
st tubes to help determine its identity. Antibody tests
n identify many viruses that cause pneumonia.

Treatment and prevention. Many people with
eumonia require complete bed rest in a hospital, but
s may not be necessary in mild cases. For viral pneu-
onia, there is no other specific treatment, though
me severe cases may require antiviral drugs. The ma-
rity of cases of viral pneumonia clear up within a few
ys or weeks. Physicians use antibiotics to treat bacte-
l pneumonia. They select the antibiotic thought to be
e most effective in killing the specific kind of bacteria
volved. Some pneumococci and other bacteria have
come resistant to antibiotics, complicating treatment.

Influenza vaccinations protect against pneumonia
used by influenza viruses. Another vaccine protects
e body from pneumonia caused by pneumococci. But
ctors recommend it only for elderly people, patients
th a long-term illness, and other people with a high
k of catching pneumonia. Michael G. Levitzky

neumothorax, *NOO moh THAWR aks,* is air or gas in
e space between the lungs and the chest wall. A thin,
ntinuous membrane called the *pleura* covers the out-
de of the lungs and the inside of the chest wall (see
eura). Normally, the part of the pleura covering the
ngs lies close to the part on the inside of the chest.
nly a very thin film of liquid separates the two parts.
dinarily, no air is present in the space between them.
air or gas enters the pleural space, the two sections of
embrane are pushed apart. When a large amount of
 or gas collects between the parts of the pleura on
e side of the chest, the lung on that side cannot fully
pand. Breathing becomes difficult, and the lung may
en collapse.

Pneumothorax may result from a wound in the chest,
ch as a knife wound, or after a sudden tear in the
ng. Infection of the pleural space by gas-producing
crobes can also cause pneumothorax. Physicians treat
eumothorax by removing the gas by suction, surgi-
cally repairing the chest or lung, or prescribing antibiot-
ics when an infection is present. Michael G. Levitzky

Pnom Penh. See Phnom Penh.

Po River is the largest waterway in Italy. It is important for the volume of water it carries from the mountains to the sea and for the fertile valley it has created along its course. The Po begins near Mount Viso, in the Cottian Alps, and flows east about 405 miles (652 kilometers) to a large delta in the Adriatic Sea (see **Italy** [terrain map]). Almost every river in northern Italy is a branch of the Po. Lakes Maggiore, Como, Lecco, Iseo, and Garda also empty their waters into the Po. The river is rapid in its upper courses but becomes a sluggish stream long before it reaches the sea. See also **Italy** (The land).

The Po River has often caused disastrous floods. About 300 B.C. the Etruscans built artificial embankments in an effort to control the waters. The river's continual deposits of silt raise the level of the water. From time to time, the embankments have been raised to heights above the river.

Some of Italy's large cities lie on the banks of the Po, including Turin, Piacenza, and Cremona. Large electric power plants operate along the upper sections of the river. Large ships can sail up the Po as far as Turin, and much freight is carried along this section of the river.

David I. Kertzer

Poaching is the illegal hunting of wild animals. Poaching occurs throughout the world and threatens the survival of many scarce species, such as elephants and rhinoceroses. When animals become extinct, the world loses much of great value. Each species contributes in a unique way to the beauty of nature.

Poachers kill animals for different reasons. Many poachers desire the valuable parts of animals' bodies. Such body parts include the horns of rhinoceroses and the ivory tusks of elephants and walruses. Poachers can sell these body parts for money or trade them for items such as guns and drugs. Other poachers capture live animals, such as small birds, to be sold illegally as pets. Some poachers merely kill animals for fun or to brag about what they poached.

Throughout history, countries have fought poachers

Peter Davey, Bruce Coleman Ltd.

Poaching threatens the survival of many endangered species. This black rhinoceros, one of the rarest animals in the world, was killed by poachers in Kenya for its valuable horn.

in different ways. For hundreds of years in England, poaching the king's deer was a crime punishable by death. Today, the methods used to combat poaching are usually less severe. Biologists study various animals to determine whether they are plentiful enough to be hunted. Species are then classified as *game animals,* which may be legally hunted, and *nongame animals,* which may not be hunted. Laws in many countries dictate when and how many game animals can be killed. Penalties include prison sentences and steep fines.

Many institutions have been established around the world to help reduce poaching. The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) is an international agreement administered by the United Nations to protect wildlife. It prohibits the trade of many nongame animals and their body parts. In the United States, the National Park System and the National Wildlife Refuge System incorporate vast areas of protected land. Many endangered species inhabit these lands. John L. Brooks II

Pocahontas, *POH kuh HAHN tuhs* (1595?-1617), was the daughter of the American Indian chief Powhatan. She worked to maintain friendly relations between the Indians and early English colonists in America. Captain John Smith, the leader of the settlers in Jamestown, Virginia, claimed that she saved his life. He wrote in his book *The Generall Historie of Virginia, New England, and the Summer Isles* (1624) that Powhatan was about to kill him with a stone war club. But Pocahontas, Smith claimed, placed her head upon his and begged her father to spare him. It is not certain that this is a true story, because Smith, in an earlier book, failed to include an account of this incident.

National Portrait Gallery, Andrew W. Mellon Collection, Washington, D.C.

Pocahontas was the daughter of an American Indian chief. This portrait was painted in England shortly before her death.

The name *Pocahontas* meant *playful one.* She was a child of about 12 at the time of the incident. She is mentioned in William Strachey's *The Histories of Travell into Virginia Britania* (1612). Strachey, the first secretary of the Virginia Colony, said Pocahontas married a chief from her tribe when she was about 14. She was not seen in the Jamestown area for about three years after that.

By 1608, fighting had broken out between the white settlers and Powhatan's Indians. Pocahontas was lured on board an English ship in 1613 and temporarily held captive. During this time, she and the settler John Rolfe fell in love. Pocahontas was converted to Christianity and baptized Rebecca. She married Rolfe in 1614.

Pocahontas went with her husband to London in 1616 to help raise funds for the struggling colonists in Virginia. The English thought of her as an Indian "princess." While waiting to sail back to America, she died of smallpox. Her son, Thomas, was educated in England. He lat went to America and became an important settler in Vi ginia. A number of noted Virginia families claim to be his descendants. James Kirby Martin

Pocatello, *POH kuh TEHL oh,* Idaho (pop. 51,466), is an air, highway, and rail gateway to the Pacific Northwest is the seat of Bannock County. Greater Pocatello includes Chubbuck and other parts of the county. The cit lies in a rich farming area. It serves as a market and shi ping center for crops and livestock. For location, see **Idaho** (political map).

Factories in Pocatello make elemental phosphorus, fabricated steel products, feed products, flour, frozen food products, malt for brewing, phosphate fertilizers, and semiconductors. The city is the home of Idaho Stat University. Tourists visit Caribou National Forest, the Fort Hall Indian Agency, the Idaho Museum of Natural History, and Ross Park.

Pocatello was founded in 1882. Land did not become available to settlers until 1891, because the area was pa of the Fort Hall Indian Reservation. Pocatello received i city charter in 1893, and was named after a Bannock Indian chief. It grew steadily with the progress of the Union Pacific Railroad, which maintains large yards there. Pocatello has a mayor-council form of government. Don Black

Podgorica, *PAWD guh REET suh* (pop. 117,875), is the capital and largest city of Montenegro, one of the two republics of Yugoslavia. Serbia is the other republic. Podgorica lies in a fertile plain near the junction of the Morava and Zeta rivers. For location, see **Yugoslavia** (map). Podgorica's cultural institutions include a univers ty, a theater, a museum of art, and a sports center. Met works in the city produce aluminum.

Romans built a castle on the site of Podgorica in A.D. 518 and a town grew up around it. Slavic tribes settled in the area in the 600's and called the town Ribnica. The town was renamed Podgorica in 1326. In 1474, it fell to the Ottoman Empire, which ruled Montenegro until th late 1800's. Much of Podgorica was destroyed during World War II (1939-1945). In 1946, the city was renamed Titograd in honor of the Yugoslav leader Josip Broz Tit An earthquake in 1979 caused widespread damage. Th city was renamed Podgorica in 1992. Sabrina P. Ramet

Podiatry, *puh DY uh tree,* is the branch of medicine concerned with the examination, diagnosis, treatment, and prevention of diseases and conditions affecting the human foot, ankle, and related structures. Podiatry is also called *podiatric medicine.* Podiatrists provide med ical and surgical treatment of problems of the foot and its related structures. They may prescribe medication and corrective shoes and also fit corrective devices. Podiatrists treat patients in their offices or in clinics, nursing homes, or hospitals.

There are seven accredited colleges of podiatric med icine in the United States. After an undergraduate education with emphasis in chemistry and biological sciences, a person takes a four-year course leading to the degree of Doctor of Podiatric Medicine (D.P.M.). Most podiatrists complete postgraduate residency training o one or more years. The American Podiatric Medical Association has its headquarters in Bethesda, Maryland.

Critically reviewed by the American Podiatric Medical Association

e, Edgar Allan (1809-1849), was an American poet, ort-story writer, and literary critic. Poe's stormy per- al life and his haunting poems and stories combined make him one of the most famous figures in Ameri- n literary history.

Poe's influence on literature has been immense. His ort story "The Murders in the Rue Morgue" (1841) is nsidered the first modern detective story. His reviews American novelist Nathaniel Hawthorne mark him as first significant theorist of the modern short story. poetry and his stories of terror are among the most luential in modern literature. Writers as diverse as the ottish writer Robert Louis Stevenson and the Russian hor Fyodor Dostoevsky have used Poe's stories to nch their own fictional experiments. Poe celebrated re forms of beauty and opposed the *didactic* (a tend- cy to instruct or moralize) in poetry. These attitudes d a foundation for later literary movements, notably mbolism (see **Symbolism**).

Poe worked as an editor and contributor to maga- es in several cities, including Richmond, Virginia; w York City; and Philadelphia. He unsuccessfully tried found and edit his own magazine, which would have nted him financial security and artistic control in at he considered a hostile literary marketplace.

During his lifetime, Poe made many enemies through challenge to moralistic limits on literature, his con- ntation with the New England literary establishment, d his biting critical style. Some readers too easily ntified Poe with the mentally disturbed narrators of tales, a belief reinforced by Rufus Griswold, Poe's lit- ry executor. Griswold wrote a malicious obituary 49) and memoir (1850) of Poe that combined half- ths and outright falsehoods about Poe's personal bits and conduct. Griswold portrayed Poe as envious, nceited, arrogant, and bad-tempered. Griswold's por- it severely damaged Poe's reputation and delayed a ious consideration of the writer's place in American rature. But Poe's later rediscovery by the French po- Charles Baudelaire, Stéphane Mallarmé, and Paul léry helped restore his reputation.

Poe's life. Poe was born on Jan. 19, 1809, in Boston. s parents were traveling actors. His father deserted family. After his mother died in 1811, Poe became a rd of John Allan, a wealthy Richmond merchant. The an family lived in the United Kingdom from 1815 to 20 before returning to Richmond. In 1826, Poe en- led at the University of Virginia. There he acquired mbling debts that John Allan refused to pay. Eventual- Poe was forced to withdraw from the university.

Poe's relationship with Allan deteriorated, and Poe en- ed in the U.S. Army in 1827. During the same year, e's first book was published. Its title was *Tamerlane d Other Poems,* "By a Bostonian." While waiting for an pointment to the U.S. Military Academy, Poe pub- ed his second volume of poems, *Al Aaraaf, Tamer- e, and Minor Poems* (1829). Both collections show the luence of the English poet Lord Byron. In 1830, Poe tered the U.S. Military Academy at West Point, New rk, where he excelled in the study of languages. But was expelled in 1831 for neglecting his duties.

Poe's *Poems* (1831) contained two important poems, Helen" and "Israfel." He began to write tales in the rly 1830's while living with his aunt Maria Clemm and her daughter Virginia. Poe suffered financial difficulties, especially after being ignored in John Allan's will. With help from the American novelist John P. Kennedy, Poe won an editorial post with the *Southern Literary Messenger* in Richmond. In 1836, Poe married Virginia, his 13-year-old cousin. For the *Messenger,* Poe contributed reviews, original or revised poems and stories, and two installments of *The Narrative of Arthur Gordon Pym.*

Poe produced several of his finest tales in the late 1830's, including "Ligeia," "The Fall of the House of Usher," and "William Wilson." These and other stories were incorporated into *Tales of the Grotesque and Arabesque* (1839). In 1841, he became an editor of *Graham's Magazine,* to which he contributed "The Murders in the Rue Morgue."

Poe won greater recognition with "The Gold Bug" (1843), a prize-winning tale that appeared in Philadelphia's *Dollar Newspaper.* The poem "The Raven" (1845) made him famous. Two more collections, *Tales* and *The Raven and Other Poems,* appeared in 1845. Early in 1845, Poe antagonized many people with a scathing campaign against the popular American poet Henry Wadsworth Longfellow for supposed plagiarisms. At a public appearance in Boston later that year, Poe admitted to being drunk, which further alienated the public.

Poe's later years were colored by economic hardship and ill health. But he produced the story "The Cask of Amontillado" (1846), "The Philosophy of Composition" (1846), and part of his "Marginalia," a collection of critical notes written for various periodicals during the 1840's.

Virginia Poe died of tuberculosis in 1847, after five years of illness. Poe then sank into poor health, and his literary productivity declined. In the middle and late 1840's, he sought to support himself as a lecturer. His lecture on "The Universe" was expanded into *Eureka: A Prose Poem* (1848), which explores the mysteries of the universe.

In 1849, Poe became engaged to marry the widowed Sarah Elmira Royster Shelton, his boyhood sweetheart. On his way to bring Maria Clemm to the wedding, Poe stopped in Baltimore. On October 3, he was found semiconscious and delirious outside a tavern used as a polling place. The cause of his death four days later was listed as "congestion of the brain," though the circumstances of his death have never been fully explained.

Poetry and poetic theory. Poe began his career as a poet, and composed or revised poems throughout his career. A tone of amused distance can be detected even in poems that critics consider serious. However, these elements coexist with themes that are more typical of the Romantic movement, such as dreams and nightmares (see **Romanticism**). Poe handled such material through images and *tropes* (figures of speech) designed to signify uncertain states of consciousness represented as lakes, seas, waves, and vapors.

Nearly all Poe's criticism on poetry was written for the magazines for which he worked. The pieces reflect a coherent, self-conscious view of poetry and of the creative process. Poe wrote "The Philosophy of Composition" to explain how he composed "The Raven." The essay opposes the Romantic assumption that the poet works in a "fine frenzy" of pure inspiration. Instead, Poe wrote a careful account of poetic creation. The essay analyzes the central role of "effect," the conscious choice of an

emotional atmosphere that is more important than incident, character, and versification. Poe also offered his famous pronouncement that the death of a beautiful woman is the most poetical topic in the world. In "The Poetic Principle" (1850), Poe claimed that poetry works to achieve "an elevating excitement of the soul," an emotional state that could not be long sustained. He further declared that a "long poem" is a contradiction in terms.

Poe believed that a poem's emotional impact was enhanced by music or "sweet sound." He thus devoted considerable attention to techniques of versification, especially in his essay "The Rationale of Verse" (1848).

Poe's "Sonnet—To Science" (1829) subtly shows how beauty is destroyed by the coldness of the modern scientific intellect. "To Helen" (1831) is a brilliant example of precision and balance and perhaps Poe's classic poetic statement on the idealization of women.

Despite its theatrical effects and stylistic flaws, "The Raven" (1845) is Poe's best-known poem and one of the most famous works in American literature. It treats his favorite theme, the death of a beautiful woman. This theme also appears in "The Sleeper" (1841) and "Ulalume" (1847). In all three poems, Poe chose elaborate musical and metrical effects, which have been widely criticized and parodied. Poe sought an *incantatory* quality in his verse—that is, a hypnotic quality of rhythm.

Reflecting his interest in musical effects, Poe made no rigid distinction between music and poetry. "Eldorado" (1849), which originated as a song of the American West about the California gold rush, is an outstanding example. Poe went beyond the poem's topical nature. The theme is universalized, as a knight learns that the true Eldorado is a wealth beyond this world.

Fiction and theory of fiction. Poe's review of the American novelist Robert Montgomery Bird's supernatural novel *Sheppard Lee* (1836) offers penetrating comments on fantasy literature. Poe distinguished genius from talent in his review of the English novelist Charles Dickens's *The Old Curiosity Shop* (1841). Critiques of the American writer Nathaniel Hawthorne's tales offer Poe's most sustained views on prose fiction. Poe approached the tale as a painter or a landscape architect might deal with his or her craft. He discussed the importance of "design," the reconciliation of diverse elements into a "unity of effect or impression." Poe's review of *Twice-Told Tales* (1842) celebrates the short prose tale as much as Hawthorne's artistry. "Tale-Writing—Nathaniel Hawthorne" (1847), in contrast, criticizes Hawthorne's lack of originality and his strong liking for *allegory*—that is, a story with both a literal and a symbolic meaning (see **Allegory**). According to Poe, the "proper uses" of prose fiction are served only when allegory is suggestive—that is, when it ceases to "enforce a truth" and offers an unobtrusive "under-current" of meaning.

Much of Poe's early fiction was written for *Tales of the Folio Club,* a series of satires on the literary pretensions of his day that was never published as a separate volume. In these pieces, serious and satirical elements coexist. These stories, the most notable of which are "Metzengerstein" and "The Assignation," do not conform to his principle of "unity of effect." Rather, the tone is a combination of "half banter, half satire." Poe's only long work of fiction, the sea story *The Narrative of Arthur Gordon Pym* (1838), may have been begun in this style. But modern critics have uncovered suggestions of mythical, religious, and visionary meaning in its ending.

Poe's most famous fictional expression of the unity of effect is "The Fall of the House of Usher" (1839). The story is a portrait of a suffering artist isolated from the tides of life. Subtle psychological meanings can also be found in "Ligeia," "The Cask of Amontillado," and "William Wilson." In all three tales, bizarre and frightening details and events conceal Poe's subtle probing of the warfare he observed in the human soul. Kent Ljungquist

Poem. See Poetry.

Poet laureate, *LAWR ee iht,* is the official poet of a state or nation. Since 1668, the king or queen of the country now known as the United Kingdom has appointed an official poet laureate. To honor special occasions, the poet laureate usually writes a formal poem called an *ode.* The poet laureate is appointed for life.

Many states in the United States have poet laureates. In 1985, Congress authorized naming a poet laureate for the nation. The Librarian of Congress makes the appointment, in consultation with former appointees, the current laureate, and poetry critics. The annual appointment runs from October to May.

Poets laureate of the United Kingdom

ᵓoetry

ᵓoetry is a type of literature in which the sound and ıeaning of language are combined to create ideas and :elings. The first part of "Break, Break, Break," a poem 'y the English poet Lord Tennyson that was first pubshed in 1842, helps show how poetry does this:

> Break, break, break,
> On thy cold gray stones, O Sea!
> And I would that my tongue could utter
> The thoughts that arise in me.

ı these four lines, Tennyson reflects on the connection etween the sea and himself. The sea breaks up on ocks much as the poet's thoughts seem to break up on is tongue before he can explain how he feels. This conection between the sea and the poet is reinforced by ıe fact that "Sea" rhymes with "me." In addition, the two nes about the sea and the two lines about the poet ave the same three-beat rhythm. Tennyson could have irectly stated how he felt by writing something like: "I /ish I could tell you how rotten I feel today." By using oetry, however, Tennyson helped his readers both unerstand and feel how he felt.

Many people are first attracted to poetry by the ound and rhythm of a poem's words. For example, chilren delight in the pleasing rhymes and strong rhythms f nursery rhymes. Youngsters often clap their hands to uch verses for the simple enjoyment of matching the hythm of their bodies with the rhythm of the language.

Poetry began in prehistoric times. Early peoples used oetic language with accompanying music in songs, rayers, and magic spells. The patterns of rhyme and hythm helped people remember and so preserve oral oetry from generation to generation. After the developıent of writing, poetry gradually became an important /ritten art. Today, millions of people throughout the /orld continue to listen to or read poetry. Many people lso write poetry.

Kinds of poetry

Through the years, poets have developed many kinds f poetry. The three main kinds are (1) lyric, (2) narrative, nd (3) dramatic.

Lyric poetry is by far the most common type of potry. The word *lyric* comes from *lyre,* a harplike instruıent played by ancient Greek poets during recitals of ıeir shorter poems. Today, lyric poetry means any short oem.

The *haiku,* a Japanese form, is one of the shortest /pes of lyric poetry. In Japanese, the haiku consists of 7 syllables arranged in three lines. The first line has 5 yllables, the second 7, and the third 5. Some English anslations of haiku try to capture their effect rather ıan imitate their form. For example, the following transıtion by the Australian poet Harold Stewart of a haiku y the Japanese poet Issa has two lines of 10 syllables ach:

> In these degenerate latter days, I stare
> Astounded: cherry-blossoms everywhere!

Other lyric forms are longer and more complicated than the haiku. The *ode* is a serious, elaborate lyric full of high praise and noble feeling. Many odes mark important public events. The *classical ode,* also called the *Pindaric ode* or *choral ode,* was developed by the ancient Greeks. It consists of three parts. The first two parts, the *strophe* and *antistrophe,* have the same pattern of rhyme. The third part, the *epode,* has a different pattern. Most odes that were developed later consist of stanzas with the same pattern of rhythm and rhyme.

The *elegy,* another common lyric, is a meditation on life and death. Many elegies mourn the death of a famous person or a close friend. The *sonnet* is a 14-line lyric with a certain pattern of rhyme and rhythm. Many sonnets are love poems. Other lyric forms include the *limerick, rondel, triolet,* and *villanelle.* For descriptions of these forms, see the table *Terms used in poetry.*

Narrative poetry tells stories. There are two chief kinds of narrative poems: (1) epics and (2) ballads.

Epics are long poems. Most epics describe the deeds of heroes in battle or conflicts between human beings and natural and divine forces. Many other epics tell of the origin or history of a people. Epics are probably the oldest surviving form of poetry. Many scholars believe that the *Iliad* and the *Odyssey,* two of the most famous epics in Western literature, were composed during the 700's B.C. These works are traditionally attributed to the Greek poet Homer. The *Iliad* describes events in the last year of the Trojan War, which was fought between Greece and the city of Troy. The *Odyssey* tells of the adventures of Odysseus, king of Ithaca, on his return home after having fought for Greece in the Trojan War.

Ballads tell shorter stories about a particular person. For example, many ballads in English literature describe the adventures of Robin Hood, a legendary outlaw who stole from rich people and gave to the poor. Some ballads date from the 1300's.

Dramatic poetry, like narrative poetry, tells stories. But in dramatic poetry, the poet lets one or more of the story's characters act out the story. Many plays are written as dramatic poetry. The difference between drama and dramatic poetry is a matter of degree. If the dialogue of a play rhymes, has repeating rhythms, or features other distinct poetic elements, the play is considered to be dramatic poetry. The English playwright William Shakespeare is the most famous dramatic poet.

In the *dramatic monologue,* the story is told in the words of only one character. Robert Browning, an English poet of the 1800's, wrote many poems in this style.

The elements of poetry

Rhythm and meter. The word *rhythm* comes from the Greek word *rhein,* which means *to flow.* Rhythm fills the world with repetition and flow, from the beat of our hearts to the rise and fall of ocean tides.

Rhythm in poetry means the flow of sound produced by language. In many poems, we can sense something repeating in the rhythm. This pattern of rhythm in a poem is called *meter.* Meter gives form to what we hear in a poem by telling us what to expect the flow of lan-

guage to do from line to line. However, the actual rhythm of any line may not follow the meter exactly. In certain poems, the rhythm varies so much from the meter that the sense of meter is almost lost. The poet's decision to follow the meter closely or to vary from it greatly depends on the particular effects the poet wants to create. The poet may also decide to use no meter at all. Much modern poetry has no meter.

Meter varies according to the sounds of the language in which a poem is written. For example, Cheyenne, an American Indian language, has whispered syllables as well as spoken ones. The meters of Cheyenne poetry reflect this characteristic. The ancient Greeks based their meters on the long and short vowels in their words.

In poetry written in English, meters are based on syllables and on *stress* (the vocal emphasis given to a syllable). Poets who work in English use three chief types of meters: (1) syllabic, (2) stress, and (3) foot-verse.

Syllabic meters are based on the number of syllables in a line. The most common syllabic meters are *continuous syllabics* and *stanzaic syllabics.*

In continuous syllabics, the poet uses the same number of syllables in each line of the poem. In stanzaic syllabics, the number of syllables in each line of the first stanza is repeated in the corresponding lines of all othe[r] stanzas.

Stress meters are based on the number of stressed syllables in a line. The stress meters most used in the tradition of poetry in English are the Folk Meters. One widely used Folk Meter is *Long Measure,* which has a pattern of four beats per line. The American poet E. E. Cummings used Long Measure in "anyone lived in a pretty how town" (1940). In the following stanza from that poem, the Long Measure pattern of four beats per line quickly establishes itself. The underlined syllables and words indicate where beats might occur:

> stars rain sun moon
> (and only the snow can begin to explain
> how children are apt to forget to remember
> with up so floating many bells down)

Great poets

Masters of poetry from the 1200's to the present are listed in chronological order. Great poets who lived before the 1200's include Homer of Greece, Virgil of Rome, and Li Po of China. Outstanding poems written before the 1200's by unknown authors include *Beowulf* (700's) and *The Song of Roland* (about 1100).

Each poet has a separate biography in *World Book.*

Dante Alighieri

William Shakespeare

T. S. Eliot

John Milton (1608-1674) Engla[nd]
John Donne (1572-1631) England
William Shakespeare (1564-1616) England
Edmund Spenser (1552?-1599) England
Pierre de Ronsard (1524-1585) France
Joachim Du Bellay (1522-1560) France
François Villon (1431- ?) France
Geoffrey Chaucer (1340?-1400) England
William Langland (1332?-1400?) England
Petrarch (1304-1374) Italy
Dante Alighieri (1265-1321) Italy

1300 1400 1500 1600

Another Folk Meter, *Common Measure,* alternates our-beat and three-beat lines. It is used in ballads, ymns, lyric poems, and nursery rhymes. "I Heard a Fly uzz," by Emily Dickinson, is in Common Measure:

> I heard a Fly buzz—when I died—
> The Stillness in the Room
> Was like the Stillness in the Air—
> Between the Heaves of Storm—
>
> The Eyes around—had wrung them dry—
> And Breaths were gathering firm
> For that last Onset—when the King
> Be witnessed—in the Room—
>
> I willed my Keepsakes—Signed away
> What portion of me be
> Assignable—and then it was
> There interposed a Fly—
> With Blue—uncertain stumbling Buzz—
> Between the light—and me—
> And then the Windows failed—and then
> I could not see to see—

When we read this poem, we pause at the end of each three-beat line. We pause because we tend to hear beats in pairs. The first line of the poem has two pairs of beats, and so we expect the following lines to repeat this pattern. Thus, we pause after the three-beat lines for the expected final beat in the second pair of beats. Such pauses are regarded as *musical pauses* because they are created by the meter of the poem. They differ from *caesuras,* which are pauses created by commas, periods, and other punctuation marks. A musical pause also differs from the felt pause that we should sense at the end of any line of poetry. When reading a poem aloud, people too often ignore the end of lines and read the poem as if it were prose. The trick in reading a poem aloud is to signal the ends of lines in some way without coming to a full stop. "I Heard a Fly Buzz" has many kinds of pauses, each adding to the poem's effect.

Foot-verse meters involve both the number of syllables and the position of the stressed syllables. These combinations form *feet.* Poets have created many types of foot-verse meters. The most widely used type by far

Gerard Manley Hopkins (1844-1889) England
Stéphane Mallarmé (1842-1898) France
Emily Dickinson (1830-1886) United States

1700 1800 1900 2000

is *iambic pentameter,* a line consisting of five *iambs.* An iamb is a two-syllable foot in which the second syllable receives more stress than the first syllable. For example, the words *indeed, between,* and *mistake* form iambs.

In many cases, the pattern of stresses in iambic pentameter is harder to hear than in stress meters. In a line of stress meter, we easily recognize the pattern of heavy stresses. In a line of iambic pentameter, however, we must consider all the syllables and compare the stresses of the two syllables that make up each foot to identify the pattern.

If a poem is said to be written in iambic pentameter, the reader can expect each line of the poem to consist of five iambs. In some poems, the rhythm of the lines fulfills that expectation, as it does in these final two lines from "Composed Upon Westminster Bridge, September 3, 1802" by the English poet William Wordsworth:

> Dĕar Gód! | thĕ vé | ry̆ hóus | ĕs séem | ăsléep;
> Ănd áll | thăt míght | y̆ héart | ĭs lý | ĭng stíll!

The syllable that has less stress in each foot is marked with a breve (˘). The syllable with greater stress is marked with an accent (ˊ). The feet are separated by vertical lines called *foot boundaries.* Marking poetry in this way to find its metrical pattern is called *scanning.*

Most poets do not try to fit the rhythm to the meter exactly. Instead, they strive for the most appropriate kind of fit for the effect they wish to create. For example, the Jamaican-born poet Claude McKay wrote "If We Must Die" (1922) in iambic pentameter. But the rhythm of the last two lines of the poem only roughly fits that meter:

> Lĭke mén | wĕ'll fáce | thĕ múr | dĕrŏus, ców | ărdly̆ páck,
> Préssed tŏ | thĕ wáll, | dýĭng, | bŭt fíght | ĭng báck!

Excerpt from "If We Must Die" by Claude McKay from *The Selected Poems of Claude McKay.* Copyright 1981 by Twayne Publishers, Incorporated. Used by permission of The Archives of Claude McKay, Carl Cowl, Administrator.

In the fourth and fifth feet of the first line, McKay used a three-syllable foot instead of an iamb. In the second line, he substituted a *trochee* for an iamb in the first and third feet. A trochee is a two-syllable foot with the stress heavier on the first syllable. The rhythm of these two lines fights against the poem's meter, much as the men in the poem fight the pack, and so helps add to the poem's sense of struggle.

Sounds. Poets often use the sounds of words to create effects in their poems. The most common method is to use words that rhyme. If the words at the ends of two

Terms used in poetry

Alexandrine, *AL ihg ZAN drihn,* is a line of verse having 12 syllables. It is the most common meter in French poetry.

Alliteration, *uh LIHT uh RAY shuhn,* occurs when two or more words begin with the same sound.

Anacrusis, *AN uh KROO sihs,* is one or more unstressed syllables at the beginning of a line that do not form part of the regular meter.

Anapest, *AN uh pehst,* refers to a three-syllable foot in which the greatest stress falls on the final syllable.

Assonance, *AS uh nuhns,* is the repetition of vowel sounds with varying consonant sounds. The words *mine* and *night,* for example, have assonance of *i* sounds.

Blank verse means poetry in unrhymed iambic pentameter.

Caesura, *sih ZHUR uh,* is a pause indicated by a comma, period, or other punctuation mark.

Catalexis, *KAT uh LEHK suhs,* or **truncation**, *truhng KAY shuhn,* is the omission of an expected unstressed syllable from the end of a line.

Consonance, *KAHN suh nuhns,* occurs when the same consonant sound is repeated.

Couplet is a pair of rhyming lines. *Closed couplets* complete a sentence in two lines. *Open couplets* continue the sentence from one pair of lines to another. *Heroic couplets* are in iambic pentameter.

Dactyl, *DAK tuhl,* is a three-syllable foot in which the first syllable receives the strongest stress.

Dimeter, *DIHM uh tuhr,* is a line of two feet.

Double rhyme has two rhyming syllables, as in *dreary* and *weary* or *market* and *park it.*

Elision, *ih LIHZH uhn,* is the dropping of a syllable, or the combining of two syllables into one.

Foot is a metrical unit of two or more syllables.

Free verse means poetry without meter and without a rhyme scheme.

Heptameter, *hehp TAM uh tuhr,* is a line of seven feet.

Hexameter, *hehk SAM uh tuhr,* is a line of six feet.

Iamb, *EYE amb,* is a two-syllable foot in which the second syllable has more stress than the first.

Iambic pentameter, *eye AM bihk pehn TAM uh tuhr,* consists of a line of five iambs.

Limerick is a five-line form of humorous verse. It is written in *Poulter's Measure,* which consists of 13 beats and has a rhyme scheme of *aabba.*

Meter means the pattern of rhythm in a poem.

Monometer, *muh NAHM uh tuhr,* is a line that consists of one foot.

Octameter, *ahk TAM uh tuhr,* is a line of eight feet.

Octave is an eight-line stanza. It commonly refers to the first eight lines of an Italian sonnet.

Onomatopoeia, *AHN uh MAT uh PEE uh,* is a word whose sound suggests the sound it refers to. For example, the word *buzz* suggests as well as refers to the sound made by bees.

Pentameter, *pehn TAM uh tuhr,* is a line of five feet.

Quatrain is a four-line stanza or four-line poem.

Rhyme scheme means the pattern of rhymes in a stanza or poem.

Rondel is a 13- or 14-line poem in which the first line, A, and the second line, B, are repeated near the middle and at the end. The 14-line form rhymes *ABba abAB abbaAB.*

Sestet is the last six lines of an Italian sonnet. It also refers to any six-line stanza or six-line poem.

Sonnet is a 14-line form with several possible rhyme schemes. The *Italian* sonnet, also called *Petrarchan sonnet,* usually rhymes *abbaabba cdecde* or *abbaabba cdcdcd.* The English sonnet, or *Shakespearean sonnet,* rhymes *abab cdcd efef gg.*

Sonnet sequence is a series of sonnets with a similar subject.

Stanza is a repeated pattern of lines, usually with a meter and rhyme scheme.

Tercet, or triplet, is a three-line stanza or a three-line poem.

Tetrameter, *teh TRAM uh tuhr,* is a line of four feet.

Trimeter, *TRIHM uh tuhr,* is a line of three feet.

Triolet is a complex eight-line French form, in which the first line, A, is repeated twice and the second line, B, once. Its rhyme scheme is *ABaAabAB.*

Trochee, *TROH kee,* is a two-syllable foot in which the first syllable is more stressed than the second.

Villanelle, *VIHL uh NEHL,* is an elaborate 19-line French form. It repeats two rhyming lines, *A* and *A′*, in an intricate pattern: *AbA′ abA abA′ abA abA′ abAA′.*

or more lines of a poem rhyme, the poem has a *rhyme scheme*. The English poet Gerard Manley Hopkins used a rhyme scheme in "Pied Beauty." This poem, written in 1877, celebrates *pied,* or *dappled,* things—that is, spotted, many-colored things:

> Glory be to God for dappled things—
> For skies of couple-colour as a brinded cow;
> For rose-moles all in stipple upon trout that swim;
> Fresh-firecoal chestnut-falls; finches' wings;
> Landscape plotted and pieced—fold, fallow, and plough;
> And all trades, their gear and tackle and trim.
>
> All things counter, original, spare, strange;
> Whatever is fickle, freckled (who knows how?)
> With swift, slow; sweet, sour; adazzle, dim;
> He fathers-forth whose beauty is past change:
> Praise him.

In the standard way of indicating a rhyme scheme, the letter *a* represents the first rhyme sound, *b* the second, *c* the third, and so on. Thus, the rhyme scheme of "Pied Beauty" is *abcabc dbcdc.*

Poets also achieve effects by using words that have similar sounds but do not rhyme. Many such words appear in "Pied Beauty." For example, the first two lines of the poem have words that begin with the same *g* sound ("*G*lory be to *G*od") and the same *c* sound ("*c*ouple*c*olour as a brinded *c*ow"). Such repetition of the same first sounds in words is called *alliteration. Consonance* occurs when the same consonant sound is repeated. The third line of "Pied Beauty" has consonance of *l* sounds ("rose-mo*l*es a*ll* in stipp*l*e") and t sounds ("*t*rou*t* tha*t* swim"). The repetition of a vowel sound is called assonance. In the fourth line of the poem, the *e* sounds and the last two *i* sounds are examples of *assonance* ("Fr*e*sh-firecoal ch*e*stnut-falls; f*i*nches' w*i*ngs"). The fifth line of "Pied Beauty" combines alliteration, consonance, and assonance. Hopkins thus created a poem that in itself is a "dappled thing" of sound.

Imagery refers to the sensations that language creates in the mind. These sensations, or images, are often thought of as being like pictures. But images are not limited to visual sensations. For example, the first three stanzas of "The Snow Man" (1923) by the American poet Wallace Stevens appeal to our sense of touch and our sense of hearing:

> One must have a mind of winter
> To regard the frost and the boughs
> Of the pinetrees crusted with snow;
>
> And have been cold a long time
> To behold the junipers shagged with ice,
> The spruces rough in the distant glitter
>
> Of the January sun; and not to think
> Of any misery in the sound of the wind,
> In the sound of a few leaves....

In these lines, such phrases as "crusted with snow," "shagged with ice," and "rough in the distant glitter" help us sense the texture of things. In the third stanza, "the sound of the wind" and "the sound of a few leaves" create images of things heard.

Poets also create images by comparing things that ordinarily have little in common. In "Little Exercise" (1946), the American poet Elizabeth Bishop compared an approaching storm to a restless dog. This comparison suggests images of both sound and movement:

> Think of the storm roaming the sky uneasily
> like a dog looking for a place to sleep in,
> listen to it growling.

Forms. Poets give form to their verse in various ways. The most common means of creating poetic form is rhyme. Some rhyme schemes have been used so often that they have become standard verse forms. One such form is the sonnet. The *Italian sonnet,* also called the *Petrarchan sonnet,* consists of an *octave* (eight-line stanza) followed by a *sestet* (six-line stanza). The rhyme scheme of the octave is *abbaabba.* The rhyme scheme of the sestet varies but often is *cdecde* or *cdcdcd.* The *English sonnet,* also called the *Shakespearean sonnet,* has a rhyme scheme of *abab cdcd efef gg.* Shakespeare used this form in his sonnets. His Sonnet 130, which was published in 1609, follows:

> My mistress' eyes are nothing like the sun—
> Coral is far more red than her lips' red—
> If snow be white, why then her breasts are dun—
> If hairs be wires, black wires grow on her head:
> I have seen roses damasked, red and white,
> But no such roses see I in her cheeks,
> And in some perfumes is there more delight
> Than in the breath that from my mistress reeks.
> I love to hear her speak, yet well I know
> That music hath a far more pleasing sound.
> I grant I never saw a goddess go;
> My mistress when she walks treads on the ground.
> And yet by heaven I think my love as rare
> As any she belied with false compare.

A poem's meter also may determine its form. For example, *blank verse* consists of unrhymed lines of iambic pentameter. The English poet John Milton wrote the great epic *Paradise Lost* (1667) in blank verse.

Much poetry, especially that written in the 1900's, has no rhyme scheme and no meter. Such poetry is often called *free verse.* The American poet Theodore Roethke used no rhyme scheme and no meter in "Root Cellar" (1943). The unpredictable form of Roethke's poem echoes the unexpected behavior of the things in the cellar:

> Nothing would sleep in that cellar, dank as a ditch,
> Bulbs broke out of boxes hunting for chinks in the dark,
> Shoots dangled and drooped,
> Lolling obscenely from mildewed crates,
> Hung down long yellow evil necks, like tropical snakes.
> And what a congress of stinks!
> Roots ripe as old bait,
> Pulpy stems, rank, silo-rich,
> Leaf-mold, manure, lime, piled against slippery planks.
> Nothing would give up life:
> Even the dirt kept breathing a small breath.

History

Ancient poetry. Poets have been an important part of many cultures since early times. In ancient Greece,

poets recited their works at religious festivals and other important public ceremonies. The major forms of ancient Greek poetry were the epic, the lyric, and the dramatic poem.

The oldest surviving Greek poems are the great epics the *Iliad* and the *Odyssey*. These works, which are attributed to Homer, were probably written during the 700's B.C. They were composed from pieces of Greek oral poetry, such as folk tales and songs. After Homer's time, poets recited the two works from memory before large audiences at Greek festivals.

Lyric poetry in ancient Greece was recited by one person or by a large group called a *chorus*. Sappho, a Greek woman poet of the 500's B.C., composed many elegant love lyrics. Many later poets have written poems consisting of four-line stanzas called *Sapphics*, which imitate the style of Sappho. Pindar, who lived during the 400's B.C., was the greatest Greek choral lyric poet. Most scholars credit him with developing the classical ode.

Greek dramatic poets included some of the finest playwrights in history. Aeschylus, Euripides, and Sophocles, all of whom lived in the 400's B.C., composed masterpieces of tragedy. Aristophanes, another Greek poet of the 400's B.C., wrote brilliant comedies.

Greek poetry strongly influenced the poets of ancient Rome. For example, the *Iliad* and the *Odyssey* served as models for the *Aeneid*, an epic composed by the Roman poet Virgil between 30 and 19 B.C. This masterpiece tells the story of Aeneas, a mythical Trojan warrior. Other outstanding poets of ancient Rome included Ovid, Catullus, and Juvenal. Ovid and Catullus composed graceful love poems. Juvenal became famous for stinging *satires*—works that ridicule certain aspects of human behavior.

The Old Testament contains beautiful poetry of the ancient Hebrews. Much of the Old Testament began as oral literature and was written down over hundreds of years. The Psalms and the Song of Solomon provide examples of some of the loveliest and most powerful Hebrew lyrics. Hebrew poets created rhythm in their verse by repeating words, ideas, and images. Other ancient cultures in which poetry flourished included those of China and India.

Medieval poetry consists of poems written during the Middle Ages, a period in European history from about the A.D. 400's to the 1500's. Most early medieval poems were epics about heroic figures, such as kings and chieftains in battle. Many of these poems were not written down and have disappeared. Two surviving epics are *Beowulf*, believed to have been composed during the 700's by one or more unknown poets; and *The Song of Roland*, written about 1100 by an unknown French poet.

Beginning about 900, lyric poetry flourished in western Europe. In France, many nobles composed and sang lyrics about courtly love. These poet-musicians were called *troubadours* in southern France and *trouvères* in northern France. A similar group, called *minnesingers*, performed in Germany beginning in the 1100's.

Much medieval poetry reflects the central role of the Christian church in European life. Christianity united a majority of Europeans under one faith, thus creating a common cultural setting in which poets shared themes. The powerful influence of the church is evident in *The Divine Comedy*, an epic written in the early 1300's by th Italian poet Dante Alighieri. Dante himself is the main character in this masterpiece, which tells of his dream-like journey through hell and purgatory to heaven.

During the 1300's, the *romance* became the chief form of poetry in England and France. Many romances told of knightly deeds and chivalry. *Sir Gawain and the Green Knight*, one of the best-known medieval romances, was written by an unknown English author in the late 1300's.

The greatest English poet of the late 1300's was Geo frey Chaucer. Chaucer drew many of his themes and techniques from French, Italian, and Latin sources. He composed many love poems and *The Canterbury Tale* (about 1387-1400), an unfinished collection of 24 loosel related stories.

Renaissance poetry refers to the poetry written in Europe from about 1450 to 1650. This poetry appeared during the Renaissance, an era of outstanding cultural achievement in Europe (see **Renaissance**). Different styles and forms of poetry became popular during this period. Many of the new developments took place in France and Italy during the second half of the 1400's. Poets in those countries used such lyric forms as *madi gals* and *pastorals*. Madrigals usually deal with love an can be set to music. Pastorals portray shepherds or country life.

The new ideas in poetry spread to England in the early 1500's. Two English poets, Sir Thomas Wyatt and the Earl of Surrey, introduced several of the new style into English literature. These styles included a 12-sylla ble line called *alexandrine;* the Italian sonnet; and the *terza rima*, a three-line stanza form made famous by Dante in *The Divine Comedy*.

The language used in Renaissance poetry also differed from that of earlier poetry. Most medieval poets had written in Latin. By the 1500's, however, many writ ers had begun to use their native language, such as Ita ian or English. In Paris, a group of seven poets called th Pléiade helped establish French as the standard language for French poetry. See **French literature** (The Pléiade).

English poets of the late 1500's produced many out standing works. One of these works was *The Faerie Queene*, a six-book epic by Edmund Spenser. The firs three books appeared in 1590, and the second three i 1596. Other major English poetry of the late 1500's included the sonnets of Michael Drayton, William Shak speare, Spenser, and Philip Sidney.

The two major groups of English poets during the 1600's were the *metaphysical poets* and the *Cavalier poets*. The metaphysical poets included Richard Crashaw, John Donne, George Herbert, and Andrew Marvell. These poets often created elaborate images called *conceits*. The roughened language and irregul meters used by the metaphysical poets have had eno mous influence on poets of the 1900's.

The Cavalier poets became known for highly polisl love poems. These poets included Thomas Carew, Ro ert Herrick, Ben Jonson, Richard Lovelace, and Sir Joh Suckling. Their verse has regular meters and flowing patterns of sound.

Dramatic poetry also flourished in England during 1500's and 1600's. Important English dramatic poets o

his period included Christopher Marlowe and Shake-peare. Marlowe wrote powerful tragedies, such as *'amburlaine the Great* (about 1587) and *The Tragical Hisory of Doctor Faustus* (about 1588). Shakespeare wrote t least 37 plays from about 1590 to 1613.

The last great English Renaissance poet was John Milon, who wrote lyrics and epics. By the time his epic nasterpiece, *Paradise Lost,* appeared in 1667, a new age ıf poetry—the *neoclassical period*—had begun.

Neoclassical poetry dominated English poetry from bout 1660 to 1800. It tried to recapture many of the litrary ideals of such classical Roman poets as Horace,)vid, and Virgil. These poets lived during the time of ıe Roman emperor Augustus, who reigned from 27 .C. to A.D. 14. As a result, neoclassical poetry is somemes called *Augustan poetry.* Neoclassical poets comosed structurally balanced verse that expressed emoons in refined, restrained ways. They used elegant ınguage and wrote with humor and wit.

The most widely used neoclassical verse form was ıe *heroic couplet,* two rhymed lines of iambic pentamter. Jean Racine and Molière, two French playwrights f the 1600's, used this form in their dramas.

The English poets John Dryden and Alexander Pope lso used the heroic couplet. Dryden was the leading nglish poet of the late 1600's. He wrote *occasional oems* (poems that celebrate particular events), dramas, nd satires. He also translated Greek and Roman clascs. Pope, the finest English poet of the early 1700's, lso wrote satires and translated classics.

Romantic poetry is said to have begun in 1798 with ıe publication of *Lyrical Ballads,* a collection of poems y the English poets William Wordsworth and Samuel aylor Coleridge. In the preface to the second edition of ıis work, published in 1800, Wordsworth defined pory as "the spontaneous overflow of powerful feelings." ıis notion contrasted markedly with the neoclassical eal of controlled, restrained poetry. Wordsworth arued that good poetry results only from the imaginative cpression of emotions that the poet has actually experiıced. The romantic style came to reflect Wordsworth's ews.

Most romantic poets used simple language and rote about common subjects, such as nature and the :tivities of daily life. Many romantic lyrics were written though the poet is speaking. Such lyrics enabled the ›et to express thoughts and feelings directly.

In addition to Wordsworth and Coleridge, the princiıl English romantic poets included William Blake, Lord ron, John Keats, and Percy Bysshe Shelley. Many ›ets of other countries also wrote in the romantic ›irit. They included Johann von Goethe of Germany, ctor Hugo of France, Giacomo Leopardi of Italy, and exander Pushkin of Russia.

Victorian poetry. Victoria reigned as queen of Great itain from 1837 to 1901. British poetry written during :s period is called *Victorian poetry.* Victorian poets ed many of the forms and some of the themes of the mantic poets. However, their works also reflected inlectual and social changes that occurred in England a result of rapid industrialization and a new theory of olution.

In 1859, the English biologist Charles Darwin pubhed his theory of evolution in *The Origin of Species.* In this book, Darwin stated that every species of life had developed from an earlier one. Darwin thus challenged long-standing religious beliefs that every species had been created separately by divine act. Many people came to doubt their traditional values. Victorian poetry reflects this loss of faith. Expanding industrialization brought new prosperity to the English middle and upper classes, while the working class suffered in wretched poverty. Many Victorian poets dealt with the contrast between the lives of the rich and the poor.

Matthew Arnold, Robert Browning, and Lord Tennyson were the most highly regarded poets of the Victorian Age. Other leading poets included Dante Gabriel Rossetti, Christina Rossetti, and Algernon Charles Swinburne.

Beginnings of modern poetry. During the second half of the 1800's, a literary movement called *symbolism* developed in France. This movement greatly influenced poetry of the 1900's. The symbolists believed that the true nature of things exists more in the mind than in appearances. Symbolist poets used images, symbols, and the musical quality in words to suggest a connection between the visible and invisible worlds.

Charles Baudelaire was the first major French symbolist poet. His collection *Flowers of Evil* (1857) was one of the first works of symbolist poetry. Baudelaire's followers included the French poets Stéphane Mallarmé, Arthur Rimbaud, and Paul Verlaine.

Poets of the 1900's were also influenced greatly by the American poets Walt Whitman and Emily Dickinson and the English poet Gerard Manley Hopkins. Although these three poets lived in the 1800's, their work had elements that became associated with modern poetry. Whitman used everyday dialect in his poems, many of which were written in free verse. His collection *Leaves of Grass,* first published in 1855, is one of poetry's landmark works. Dickinson wrote remarkably powerful and imaginative poetry that features concentrated language, familiar subjects, and original variations of traditional meters. Hopkins showed how sound patterns can unify a poem and how sound affects the imagination.

Poetry of the 1900's has ranged widely in style and form. Much of the poetry is free verse and moves with the varied rhythms of everyday speech. The *imagists,* a group of English and American poets who became important during the early 1900's, helped popularize the use of varied rhythms. They also emphasized sharp, clear images in their works. The imagists were led by the American-born poet Ezra Pound.

Two of the most influential poets of the 1900's were William Carlos Williams of the United States and the American-born T. S. Eliot. Williams wanted poetry to be more like spoken language. The rhythms of his verse were determined by the feelings and ideas of a poem rather than traditional poetic forms. Eliot, who became a British citizen, also departed from conventional techniques. His complicated long poem *The Waste Land* (1922) is one of the most important works of modern poetry. Its jagged style and odd combinations of words, ideas, and symbols set a new direction for poetry.

During the 1950's and 1960's, many poets used frankly autobiographical material in their works. American poets called *beats* condemned middle-class life and attacked what they believed to be social and political in-

justice. Two prominent beat poets were Allen Ginsberg and Lawrence Ferlinghetti. *Confessional poets* wrote about intimate personal experiences, such as sexuality and mental illness. These poets included Robert Lowell, Sylvia Plath, and Anne Sexton of the United States.

From the early 1900's through the 1960's, traditional poetic forms also thrived. Major poets who used conventional language and forms included the English-born W. H. Auden; Dylan Thomas of Wales; William Butler Yeats of Ireland; and Robert Frost, John Crowe Ransom, and Wallace Stevens of the United States.

The leading poets of the 1960's through the 1980's represented an incredible range of style, form, and content. They included Margaret Atwood of Canada and Robert Creeley, Jorie Graham, Donald Justice, Galway Kinnell, Denise Levertov, W. S. Merwin, Adrienne Rich, William Stafford, Robert Penn Warren, and Richard Wilbur of the United States. In other countries, they included Ted Hughes and Philip Larkin of the United Kingdom, Odysseus Elytis of Greece; Eugenio Montale of Italy; Octavio Paz of Mexico; Czesław Miłosz of Poland; and Yevgeny Yevtushenko of the Soviet Union.

In the 1980's and 1990's, American poetry was characterized by the increasing recognition of poets from traditionally underrepresented groups, such as women, Native Americans, and African Americans. These poets included Leslie Marmon Silko, Rita Dove, and Gary Soto.

Poincaré, *pwan ka RAY,* **Raymond,** *ray MAWN* (1860-1934), served four times as premier of France, and was president of France from 1913 to 1920. He was a strong leader and gained a reputation as a clever financier and an ardent nationalist.

Poincaré first became premier of France in 1912 and tried to strengthen French alliances. In 1922, after his term as president of France ended, he became premier again. The Treaty of Versailles, which ended military actions against Germany in World War I (1914-1918), required Germany to pay *reparations* (compensation for war damages) to France. In 1923, after the Reparations Commission declared Germany in default, Poincaré ordered French troops into the Ruhr to force Germany to

pay (see **Ruhr** [History]). Poincaré was defeated in the 1924 elections and resigned as premier.

Poincaré served as premier again from 1926 to 1928, during a financial and political crisis. His efforts to revive the economy won him the title "savior of the franc." He resigned in 1929, after a fourth premiership. Poincaré was born in Bar-le-Duc, France. John F. Sweets

Poinciana, *POYN see AN uh,* is the name of several species of tropical flowering trees. The most important species, the *royal poinciana,* is native to Madagascar but has been widely planted in warm climates because of its

© E. R. Degginger

Flowers of the royal poinciana grow in immense clusters on the tree's branches, shown here. Royal poincianas grow along many roads in southern Florida and the West Indies.

immense clusters of brilliant flowers. Each flower is from 3 to 4 inches (8 to 10 centimeters) across, with 5 widely spreading red petals. One of these petals is streaked and dotted with yellow. The tree produces purplish-brown seed pods that may be more than 2 feet (60 centimeters) long. The pods contain hard, oblong beans. In some countries, people burn the pods as fuel.

The royal poinciana has lacy, fernlike leaves, divided into many leaflets. The strong, gnarled trunk with its spreading branches may grow 40 feet (12 meters) high.

An unrelated species, the *dwarf poinciana,* is a shrub native to tropical America. The shrub has fernlike leaves and clusters of reddish-yellow blossoms that grow at the ends of long, slender stalks. Walter S. Judd

Scientific classification. Poincianas belong to the pea family, Fabaceae or Leguminosae. The scientific name for the royal poinciana is *Delonix regia.* The dwarf poinciana is *Caesalpinia pulcherrima.*

Poinsettia, *poyn SEHT ee uh* or *poyn SEHT uh,* is a popular house plant often used as a Christmas decoration. It has tiny yellow flowers surrounded by large, colored *bracts* (modified leaves). These bracts resemble flower petals and are commonly bright red. Some poinsettia bracts are pink, white, or other colors.

Poinsettias are native to Mexico. A wild poinsettia r y grow 2 to 15 feet (0.6 to 4.6 meters) tall. It begins to bloom when days become shorter in the fall. During long summer days, the plant remains a green shrub. I cold climates, people must keep poinsettias indoors potted plants. A potted poinsettia grows 1 to 4 feet (3 120 centimeters) tall.

The poinsettia was named for Joel R. Poinsett, who came the first United States ambassador to Mexico in 1825. He introduced the plant to the United States wh he returned home. Other common names for the poi settia include the Christmas flower, lobster flower, ar Mexican flame leaf. The plant's hollow stems contain milky sap that can irritate the skin and eyes.

Paul Ecke III

Scientific classification. The poinsettia belongs to the spurge family, Euphorbiaceae. Its scientific name is *Euphorb pulcherrima.*

See also **Flower** (picture: Poinsettias); **Leaf** (picture: Bright red bracts).

Pointer is a dog used to hunt quail and other game birds. The dog is called *pointer* because it stops as st as a statue when it smells a bird, and *points* by facing the direction of the bird, often with one of the front paws lifted and its tail held out stiffly behind. The poi er is classed as a sporting dog and as a field dog, alo with setters, spaniels, and retrievers. Setters, spaniels and retrievers usually have long hair, but the pointer a a short, smooth coat. The pointer stands from 23 to 2 inches (58 to 71 centimeters) high at the shoulder and weighs from 45 to 75 pounds (20 to 34 kilograms). Its coat is white with patches of lemon, *liver* (reddish-brown), black, or orange. The pointer has speed and keen sense of smell. It is popular in America and England for hunting and field trails.

Critically reviewed by the American Pointer Club

Pointillism. See **Seurat, Georges; Painting** (Postimpressionism).

Poison is a substance that causes injury or illness when introduced into the body. Poisons may be swallowed, inhaled, injected, or absorbed by the skin or body membranes. The study of poisons is called *toxicology.*

The most potent poisons are usually found only in laboratories. They cause few deaths because they seldom occur in everyday surroundings. Most deaths a caused by weaker poisons contained in common hou hold products. About 1 million to 2 million human be ings suffer from poisoning each year in the United States, and several thousand deaths result. Many poi sonings take place when people fail to pay attention labels and instructions on containers of chemical sub stances. Poisons found in farm and household produ cause most poisonings and deaths in the United Stat These products include insect sprays, rat poisons, cl ing and polishing compounds, and such fuels as gas line. Even detergents have caused fatal poisonings w swallowed. A person also may be poisoned by impr erly taking medications, by abusing such substances alcohol, or by taking mind-altering drugs, such as co caine and heroin.

To avoid poisonings, never eat untested foods, su as wild mushrooms or berries, or foods in unlabelec

containers. Keep all medicines and chemicals out of the reach of small children. Children are more sensitive to poison than adults, and a smaller amount may cause a child's death.

Poison control centers have been set up in many hospitals to give emergency information to doctors and the public. They furnish first-aid information and advise physicians and emergency personnel on the appropriate *antidote.* An antidote is a substance that relieves the harmful effects of poisons.

Poisons can be useful and even lifesaving. Useful medicines, such as *curare* and *ouabain,* were discovered because they were used first as poisons on arrows. Ouabain is similar to the drug *digitalis* (see **Digitalis**).

Fungi, plant, and animal poisoning. Poisons produced by living organisms are called *toxins.* Some fungi produce toxins that are dangerous to human beings when swallowed in infested food. For example, some mushrooms have a toxic effect when they are eaten.

Many plants, such as larkspur and poison ivy, produce toxins that can be dangerous for human beings and livestock. Plant roots, stems, leaves, seeds, and fruits may contain poison.

Many animals have poisonous bites or stings. These include bees, wasps, scorpions, snakes, spiders, octopuses, and snails. Most animals use their poison to defend themselves or to hunt prey. Some fish, such as stingrays, have poisonous spines. Some salamanders, frogs, and toads have poison in their skin. For more information, see the *World Book* articles on **Snakebite** and each of the above animals.

Kinds of poisons. Scientists classify poisons in many different ways. A common classification lists five kinds: (1) corrosive poisons, (2) irritant poisons, (3) systemic poisons, (4) poisonous gases, and (5) poisonous foods.

Corrosive poisons destroy living tissue that they touch. Hydrochloric acid, nitric acid, and *sodium hydroxide* (lye) are corrosive poisons. A person who swallows this type of poison may destroy the tissues in his or her mouth and throat.

Irritant poisons cause *inflammation* (swelling and soreness) of the mucous membranes. These membranes line many air passages of the body, such as the nose. Irritants also affect the stomach, intestines, and nerve centers. Arsenic, lead, and most of the metallic poisons are irritant poisons. Arsenic causes vomiting and may affect the heart, kidneys, and other organs.

Systemic poisons attack the nervous system and other important organs, such as the kidneys, liver, and heart. Strychnine, a common rat poison, causes convulsions and difficulty in swallowing. Hydrocyanic acid and overdoses of heroin and cocaine may cause death. Poison from the belladonna plant produces hot flashes, thirst, and *delirium* (disorder of the mind). Many sedatives, such as barbiturates, are systemic poisons when taken in large doses. In addition, bites from some snakes, insects, and spiders can cause systemic poisoning.

Poisonous gases make breathing difficult and can cause death. Some poisonous gases, such as carbon monoxide from automobiles and gas heaters, are especially dangerous because they are difficult to notice at first. A number of poisonous gases irritate the lungs, eyes, nose, or skin.

Food poisoning can come from eating certain chemicals or organisms and their toxins. Chemicals, such as insecticides, and plants and animals, such as hemlock and certain shellfish, can cause food poisoning.

Botulism, poisoning caused by a toxin produced by bacteria, can cause paralysis and death.

Critically reviewed by the American Red Cross and Frank Welsch

Related articles in *World Book* include:

Poison gas. See **Chemical-biological-radiological warfare; Gas mask; Fumigation.**

Poison ivy is a kind of harmful vine or shrub in the cashew family. It grows plentifully in parts of the United States and southern Canada. Poison ivy usually grows as a vine twining on tree trunks or straggling over the ground. But the plant often forms upright bushes if it has no support to climb upon. Plants related to poison ivy include *poison oak,* which grows throughout much of Pacific North America and in parts of the eastern United States, and *poison sumac,* which grows in the eastern United States. Poison oak and poison sumac both are shrubs.

The tissues of all these plants contain a poisonous oil somewhat like carbolic acid. This oil is extremely irritating to the skin. It may be brushed onto the clothing or skins of people coming in contact with the plants. Many people have been poisoned merely by taking off their shoes after walking through poison ivy. People also can get poisoned from other people, but only if the oil remains on their skin. The eruptions themselves are not a source of infection.

Appearance. The leaves of poison ivy are red in early spring. Later in spring, they change to shiny green. They turn red or orange in autumn. Each leaf is made up of three leaflets more or less notched at the edges. Two of the leaflets form a pair on opposite sides of the leafstalk, while the third stands by itself at the tip of the leafstalk. Small greenish flowers grow in bunches attached to the

WORLD BOOK illustration by Lorraine Epstein

Poison ivy has leaves that consist of three leaflets. They contain a poisonous oil that irritates the skin. The plant's white, berrylike fruit also is poisonous.

main stem close to where each leaf joins it. Later in the season, clusters of poisonous, berrylike drupes form. They are whitish, with a waxy look.

Control and treatment. Efforts have been made to destroy these plants by uprooting them or by spraying them with chemicals. But poison ivy and poison oak are so common that such methods have not been very effective in eliminating them. Contact with the plants should be avoided.

After the oil has touched the skin, it usually takes some time for it to penetrate and do its damage. Before this happens, it is wise to wash the skin thoroughly several times with plenty of soap and water. Care should be taken not to touch any part of the body, for even tiny amounts of the oil will cause irritation. If poisoning develops, the blisters and red, itching skin may be treated with dressings of calamine lotion, Epsom salts, or bicarbonate of soda. Jerry M. Baskin

Scientific classification. Poison ivy, poison oak, and poison sumac belong to the cashew family, Anacardiaceae. Poison ivy is classified as *Rhus radicans* or *Toxicondendron radicans.* Poison oak is *R. diversiloba* or *T. diversilobum* and poison sumac is *R. vernix* or *T. vernix.*

See also **Poison oak; Sumac; Virginia creeper**.

Poison oak is a plant related to poison ivy and poison sumac. It grows as a bush or vine. The leaves of poison oak usually consist of three leaflets. Each leaflet has several lobes and may resemble the leaf of the white oak tree. Small greenish or yellowish flowers and hairy, berrylike, light-colored fruits cluster at the point where the leafstalk joins the stem.

Two species of poison oak live in North America. *Eastern poison oak* grows from Long Island, New York, to northern Florida and west to West Virginia, Texas, and southern Kansas. *Western poison oak* grows from the Lower California peninsula in Mexico to British Columbia in Canada.

Poison oak has sap that can irritate the skin. All parts of the plants contain the sap. In case of contact with poison oak, wash the affected areas immediately and thoroughly with soap and water. If such symptoms as blisters or swelling are severe, see a physician.

Jerry M. Baskin

Scientific classification. Poison oak belongs to the cashew family, Anacardiaceae. The scientific name for eastern poison oak is *Toxicodendron pubescens.* Western poison oak is *T. di-versilobum.*

WORLD BOOK illustration by Bridgette James, Wildlife Art Ltd.

Western poison oak can grow as a bush. Its leaves usually consist of three leaflets. This kind of poison oak grows from the Lower California peninsula in Mexico to British Columbia in Canada.

See also **Leaf** (illustration: Leaf edges).

Poison sumac. See **Sumac**.

Poisonous plant is any plant that is injurious to human beings or to animals. There are many kinds of poi sonous plants. Some kinds are merely unwholesome, are only moderately poisonous. Others contain substances that are among the deadliest poisons.

About 700 kinds of poisonous plants grow in the United States and Canada. Many look, smell, or taste d agreeable, and so people and animals avoid them. But even familiar food plants may have poisonous parts. F example, the leaves of potato and rhubarb plants are poisonous, as are the pits of apricots, cherries, and peaches. People should never eat or even chew any p of a plant that they do not know is harmless. In case of possible poisoning, a physician or a poison control ce ter should be called immediately.

The deadliest plant poison occurs in the seeds of th rosary pea. Craftworkers in many parts of the world us these pretty red-and-black seeds in making bracelets, necklaces, and rosaries. A person can be killed by eati one rosary pea seed. Another powerful poison occurs the oleander plant. Some people have died from eatin meat roasted on an oleander stick. Many have been killed by eating poisonous mushrooms, which cannot easily be distinguished from edible species. Poisonou plants have also killed many farm animals.

Not all poisonous plants do their harm by being eat en. Some, such as poison ivy and manchineel, irritate the skin or eyes. Certain others, known as *allergens,* a harmful only to people who are sensitive, or allergic, t them. The pollen of ragweed is an allergen that cause hay fever and asthma. See **Allergy**.

Some families of flowering plants contain many ve poisonous species. For example, the spurge family, Eu

Some poisonous plants

Name	Poisonous plants
Aconite (Monkshood)	Flowers, leaves, roots
Azalea	Entire plant
Belladonna	Entire plant, especially berries
Castor bean (Castor-oil plant)	Seeds
Chinaberry	Berries
Daphne	Bark, berries
Death camas	Bulbs
Foxglove	Entire plant
Gelsemium (Jessamine)	Entire plant
Hyacinth	Bulbs
Jimson weed (Datura)	Entire plant
Mistletoe	Berries
Mountain laurel	Entire plant
Mushrooms, poisonous	Entire plant
Narcissus	Bulbs
Nightshade	Entire plant, especially u ripe berries
Oleander	Entire plant
Poison hemlock	Leaves, roots, seeds
Potato	Green parts, spoiled tub
Rhododendron	Entire plant
Rhubarb	Leaves
Tobacco	Leaves
Water hemlock (Cowbane, Snakeroot)	Roots, young leaves
Yew	Bark, needles, seeds

horbiaceae, includes the cassava, croton, and the cas-or-oil plant, all poisonous. The nightshade family, olanaceae, includes such wholesome vegetables as the omato, potato, and eggplant. But it also contains such leadly members as belladonna, henbane, jimson weed, ind several kinds of nightshades. Several exceedingly oisonous plants, including aconite, larkspur, and helle-ore, belong to the crowfoot family, Ranunculaceae.

People make use of many kinds of poisonous plants. ome are lovely garden flowers. Others are used in naking insecticides. Many of the most valuable drugs ised in medicine are poisons extracted from plants and jiven in controlled doses. They include aconite, at-opine, cocaine, digitalis, hyoscine, morphine, quinine, ind strychnine. Jerry M. Baskin

Poitier, *PWAH tee ay,* **Sidney** (1927-), is an American motion-picture actor. He became the first African American to rise to the top in the film industry as a leading man rather than as a singer, dancer, or comedian. Poitier has appeared in a number of movies that deal realistically with racial problems in the United States. These films include *No Way Out* (1950), *The Blackboard Jungle* (1955), *Edge of the City* (1957), *Guess Who's Coming to Dinner* (1967), and *In the Heat of the Night* (1967). Poitier won an Academy Award for his performance in *Lilies of the Field* (1963).

© Columbia Pictures

Sidney Poitier

Poitier was born in Miami and grew up in the Bahamas. About 1945, he began taking acting lessons at the American Negro Theater in New York City. He appeared on the Broadway stage in *Anna Lucasta* (1948) and *A Raisin in the Sun* (1959). His other films include *Cry, the Beloved Country* (1952), *Porgy and Bess* (1959), and *For Love of Ivy* (1968). Poitier also wrote two autobiographies, *This Life* (1980) and *The Measure of a Man* (2000). Louis Giannetti

Poitiers, *pwah TYAY,* **Battle of,** was fought in 1356, near the present French town of Poitiers. A famous English victory in the Hundred Years' War resulted from the Battle of Poitiers. The English forces were led by Edward, "the Black Prince" of England. King John II of France led the French troops. The English were greatly outnumbered, but the Black Prince fought skillfully. At the height of the battle the English horsemen suddenly appeared behind the French lines. The French fled, leaving King John II and his son Philip to be captured.

Two other famous battles took place at or near Poitiers. In 507, a Frankish king named Clovis defeated the Visigoths there. In 732, Charles Martel, another Frankish king, turned back Muslim invaders in fighting that began near Tours and ended near Poitiers. The 732 conflict, called the Battle of Poitiers or Battle of Tours, stopped the spread of Islam to Europe. Robert S. Hoyt

See also **Edward** (The Black Prince).

Poker is a card game in which players make bets on the cards they hold or hope to hold. There are two basic types of poker, *draw* and *stud*. In draw poker, each player is dealt five cards. Players may then discard unwanted cards and *draw* (receive) the equivalent number of new cards. Players bet both before and after the draw.

There are several forms of stud poker. In five-card stud, players are dealt one card facedown and one card faceup. Then players are dealt three additional cards faceup. Bets are placed after each round of cards is dealt. Seven-card stud games follow the same general rules except that players are each dealt seven cards. The best five-card hand out of the seven wins.

The following is the ranking of cards, from highest to lowest, for poker games in which the high hand wins:

Royal flush: A-K-Q-J-10 (all of one suit)

Straight flush: 2-3-4-5-6 (any five cards in sequence, all of one suit)

Four of a kind: 9-9-9-9-J (any four cards of the same value)

Full house: 8-8-8-J-J (any three of a kind plus a pair)

Flush: 4-7-9-J-K (any five cards of the same suit)

Straight: 7-8-9-10-J (any five cards in sequence from any suit)

Three of a kind: 6-6-6-4-Q (any three cards of the same value)

Two pairs: 7-7-10-10-5

One pair: J-J-7-9-A

Highest card: A-Q-9-8-4 beats A-Q-8-7-5

If two hands are of the same rank, the hand with the higher cards wins. Dwight Chuman

Pokeweed is a tall, branching perennial herb with greenish-white flowers and a red stem. It grows natively in waste places and along roadsides from Ontario to Florida, and west to Texas and Minnesota. It has been introduced into western North America and into other continents. Pokeweed grows 4 to 10 feet (1.2 to 3 meters) high. In fall, the berries ripen to a deep purple-black. The plant is known locally as *poke, scoke, pigeonberry, pokeberry, poke salet,* and *inkberry.*

The stems, leaves, seeds, and large fleshy roots of the pokeweed are poisonous. The plants must be cut off below ground level to kill them. The leafy sprouts are edible if cooked properly. The berries may be used as ink and food coloring. The roots and berries have been used to treat inflammation and skin diseases. Pokeweed is a source of several chemical compounds used in cancer research.

Donna M. Eggers Ware

Scientific classification. Pokeweed is in the pokeweed family, Phytolaccaceae. It is *Phytolacca americana.*

Poland is a land of beautiful countryside and rapidly growing cities. Rolling hills and rugged mountains rise in southern Poland, *left*. Since the mid-1900's, many Poles have moved to towns and cities, such as Warsaw, *right*. Today, most of Poland's people live in urban areas.

Poland

Poland is a large nation in central Europe. It borders on the Baltic Sea. Warsaw is its capital and largest city.

Poland is named for the Polanie, a Slavic tribe that lived more than a thousand years ago in what is now Poland. The name *Polanie* comes from a Slavic word that means *plain* or *field*. Flat plains and gently rolling hills cover most of the country.

At one time, the people of Poland ruled an empire that stretched across most of central Europe. But foreign powers conquered and divided Poland and brought an end to its existence as a separate nation. In 1918, however, after more than a hundred years of foreign rule, Poland became an independent republic.

Poland experienced great economic, political, and social changes during the 1900's. Before World War II (1939-1945), Poland was largely agricultural, and most of the people were poor farmers. After the war, Poland began to develop into an industrial nation. Many people moved to the cities to take jobs in factories.

In the mid-1940's, Poland became a Communist country. The Communist Party controlled the Polish government and placed many restrictions on the freedom of the people. The party maintained power continuously until 1989, when Poland held its freest parliamentary elections since the Communists took control. Non-Communists took office for the first time since the 1940's. Restrictions on the freedom of the Polish people began to be lifted.

Janusz Bugajski, the contributor of this article, is Director of East European Studies at the Center for Strategic and International Studies in Washington, D.C.

Government

National government. Poland is a republic. Its current constitution went into effect in 1997.

The National Assembly is Poland's parliament. It has two houses. The lower house, called the Sejm, has 460 members. The upper house, or Senate, has 100 members. Members of both houses serve four-year terms.

Facts in brief

Capital: Warsaw.
Official language: Polish.
Official name: Rzeczypospolita Polska (Republic of Poland).
Area: 124,808 mi² (323,250 km²). *Greatest distances*—east-west, 430 mi (692 km); north-south, 395 mi (636 km). *Coastline*—277 mi (446 km).
Elevation: *Highest*—Rysy peak, 8,199 ft (2,499 m) above sea level. *Lowest*—sea level.
Population: *Estimated 2002 population*—38,835,000; density, 311 per mi² (120 per km²); *distribution*, 62 percent urban, 38 percent rural. *1988 census*—37,878,641.
Chief products: *Agriculture*—barley, hogs, potatoes, rye, sugar beets, wheat. *Manufacturing*—chemicals, food products, iron and steel, machinery, ships, textiles. *Mining*—coal, copper, silver, sulfur.
National anthem: "Jeszcze Polska nie Zginęla" ("Poland Has Not Yet Perished").
Money: *Basic unit*—zloty. One hundred groszy equal one zloty.

he duties of the National Assembly include passing ws and supervising the other branches of the govern- ent.

The president is the head of state. The president's owers include the ability to declare a state of emer- ency, to veto legislation (which may be overturned by e Sejm), and to dissolve the National Assembly. The resident is elected to a term of five years.

The Sejm appoints a Council of Ministers, which car- es out the operations of the government. The Council f Ministers includes a prime minister and a number of ther ministers. The prime minister is the head of the overnment.

Local government. Poland is divided into 16 *voivod- hips* (regions). A leader called a *voivod,* appointed by e prime minister, heads each region. The regions are ivided into *powiats* (districts), which are made up of *minas* (communities). Each region, district, and commu- ity has an elected council.

Politics. Poland's most important political organiza- ons include the Democratic Left Alliance, the Freedom nion, the Polish Peasant Party, and Solidarity Electoral ction. The Freedom Union and Solidarity Electoral Ac- on favor a free enterprise economy. Solidarity Electoral ction is the political arm of Solidarity, which is an or- anization of trade unions. The Democratic Left Alliance a Communist party, and its members are in favor of ore government control of the economy. The mem- ers of the Polish Peasant Party want agricultural reform aid small landowners, and they think Poland should low its move to a free enterprise economy.

Courts. The Supreme Court is the highest court of oland. The Council of State appoints Supreme Court idges to five-year terms. The judicial system also in- ludes province courts and county courts.

Armed forces. About 240,000 men serve in Poland's rmy, navy, and air force. Men may be drafted at age 19 serve 18 months of active duty in the armed forces.

People

Almost all of the people of Poland are Poles. They are escended from Slavic tribes that settled on the Vistula nd Warta rivers several thousand years ago. Polish, the fficial language, is related to Czech, Slovak, and other lavic languages.

Minority groups make up only a small percentage of e population. The largest minority groups are Belaru- ians, Germans, and Ukrainians.

Way of life

Housing. In the cities, most Polish families live in sim- le two- or three-room apartments. In rural areas, small rick or wooden cottages provide housing.

Food. Bread, pork, sausages, potatoes, apples, and lairy products are favorite foods. Meaty stews, hearty eet or cabbage soup, and mushrooms are popular. The olish people also enjoy rich pastries and fish, especial- y on holidays.

Recreation. Camping and hiking are some of the opular recreational activities in Poland. Poles also enjoy occer and other sports.

Religion. The Poles adopted Christianity in A.D. 966. hroughout their history, they remained loyal to the Ro- nan Catholic Church, though people in neighboring countries practiced Protestant or Eastern Orthodox reli- gions. During the 1800's, when Poland did not exist as a separate nation, loyalty to the Roman Catholic Church helped hold the Polish people together.

In the late 1940's and early 1950's, the country's Com- munist leaders tried to destroy the influence of the Ro- man Catholic Church in Poland. They restricted religious practices and imprisoned many priests. Polish Catholics resisted, however. In 1956, after antigovernment riots took place, the government discontinued most of its policies against the Roman Catholic Church. Today, Poles have complete freedom of religion.

A large majority of the people of Poland are Roman Catholics. There are thousands of Roman Catholic churches in the country as well as thousands of reli- gious instruction centers. The Roman Catholic Church also operates the Academy of Catholic Theology in War- saw and the Catholic University of Lublin. Religious mi- nority groups in Poland include Protestants, Muslims, Jews, and members of various Eastern Orthodox Churches.

Education. Poles have a long tradition of respect for education. Polish scholars, such as the astronomer Nico- laus Copernicus, have made important contributions in many fields. The first Polish university, the University of Kraków (now Jagiellonian University), was founded in 1364. Poland established a government ministry of edu-

Poland's national flag, flown by the people, *left,* has red and white stripes.The state flag, used by the government, includes the coat of arms, *right.* An eagle has been used on the Polish coat of arms since the 1200's.

cation as early as 1773. Until the 1900's, however, education was reserved for only a small, privileged section of the population. Today, almost all adult Poles can read and write. For the country's literacy rate, see **Literacy** (table: Literacy rates).

Polish law requires children from age 7 to 15 to attend school. Most students attend free, government-operated schools. But an increasing number of students enroll in private schools.

After completing the elementary school program, students may attend vocational schools or four-year secondary schools. Secondary school graduates must then pass entrance examinations for entry into schools of higher education.

Poland has 12 universities. It also has many technical institutes and other specialized schools.

The arts. Poland has produced many outstanding artists, musicians, and writers. Cultural life in Poland flourished during the 1400's and 1500's. In the 1500's, the poets Mikołaj Rej and Jan Kochanowski were among the first writers to use the Polish language for their works.

Polish culture also flourished during the 1800's, when the Polish national identity was being threatened by the Germans and the Russians. The paintings of Jan Matejko portrayed scenes from Polish history. The composer Frédéric Chopin wrote many works based on Polish dances, such as the mazurka and the polonaise. Another composer and pianist, Ignace Jan Paderewski, became a leading Polish statesman. Outstanding Polish writers of the 1800's included the poet Adam Mickiewicz, the playwright Stanisław Wyspiański, and the novelist Henryk Sienkiewicz. Sienkiewicz won the Nobel Prize for litera-

ture in 1905 for his works, which include the novel *Quo Vadis?* Another Polish novelist, Władysław Reymont, won the Nobel Prize for literature in 1924 for *The Peasants* and other novels. Two Polish poets have won Nobel Prizes for literature. Czesław Miłosz received the award in 1980, and Wisława Szymborska in 1996.

Many Poles have won fame in the graphic arts, especially in poster design. Movies are also a popular art form in Poland.

Beginning in the late 1940's, Poland's Communist leaders restricted cultural activity that did not promote Communist goals. But a series of antigovernment protests from the 1950's to the 1980's resulted in increases in cultural freedom. Today, there are few, if any, restrictions on cultural activities. The government has encouraged the preservation of traditional folk arts and music.

The land

Land regions. Poland can be divided into seven land regions: (1) the Coastal Lowlands, (2) the Baltic Lakes Region, (3) the Central Plains, (4) the Polish Uplands, (5) the Carpathian Forelands, (6) the Sudeten Mountains, and (7) the Western Carpathian Mountains.

The Coastal Lowlands extend in a narrow strip along the Baltic coast of northwestern Poland. Sandy beaches line much of the generally smooth coastline. The coast forms natural harbors at Gdańsk, Gdynia, and Szczecin. These three ports are the only major cities located in the lowlands.

The Baltic Lakes Region covers most of northern Poland. This scenic, hilly area has thousands of small lakes. Forests and peat bogs (swamps made up of decayed plants) cover parts of the area. Most of the land is not good for farming, though some farmers raise potatoes and rye. Lumbering is the most important industry. The Baltic Lakes Region is thinly populated. It is a popular vacation spot, where many Poles enjoy camping, hiking, and fishing.

The Central Plains stretch across the entire width of Poland south of the Baltic Lakes Region. The low-lying plains make up Poland's major agricultural area, though other regions have richer soil. Farmers in the plains grow potatoes, rye, sugar beets, and other crops. This region has several of Poland's most important cities, including Poznań, Warsaw, and Wrocław.

The Polish Uplands consist of hills, low mountains, and plateaus that rise south of the plains region. The densely populated uplands contain most of Poland's mineral wealth and much of its richest farmland. One of the world's largest coal fields lies around the city of Katowice. Coal-mining and metal-processing industries

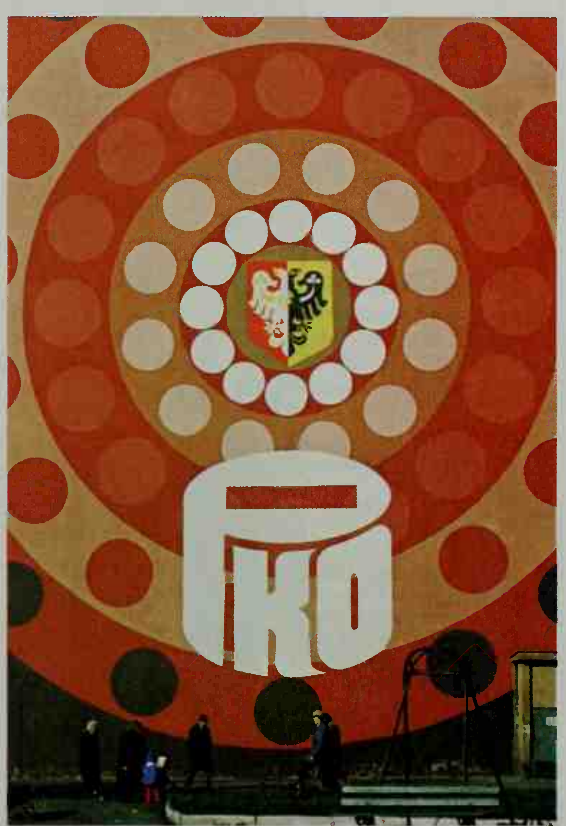
have made the Katowice area the most highly industrialized region in Poland. Copper, lead, and zinc are also found in the uplands. Fertile soil covers much of the area, especially in the east. Corn, potatoes, and wheat rank among the region's major crops.

The Carpathian Forelands lie within the branches of the Vistula and San rivers in southern Poland. Much of this region is densely populated. Crops thrive in the rich soil that covers parts of the gently rolling forelands. Iron and steel industries have developed around Kraków, the region's most important manufacturing center.



The Sudeten Mountains border southwestern Poland. Forests cover the rounded peaks of the Sudetens, most of which are located less than 5,000 feet (1,500 meters) above sea level. The valleys and foothills are used for crops and pastureland. Textile industries operate in a large number of the small cities and towns of the Sudeten Mountains.

The Western Carpathian Mountains form the southernmost region of Poland. These steep, scenic mountains rise up to 8,199 feet (2,499 meters) at Rysy peak, the highest point in Poland. Rural towns and villages are scattered throughout the region. Bears, wildcats, and other animals live in the thickly forested mountains, and the region has several national parks.

Rivers and canals form a network of navigable waterways in Poland. The longest river, the Vistula, flows 675 miles (1,086 kilometers) through Poland from the Western Carpathians to the Baltic Sea. Other important rivers include the Bug, the Oder, and the Warta.

Climate

The climate of Poland varies greatly from one part of the country to another. In general, the coast has milder weather than the inland regions, and the mountainous

Hervé Gloaguen, Woodfin Camp, Inc.

A huge poster in the city of Wroclaw serves as an advertisement for the National Bank of Poland. Many Polish artists have won widespread fame for their bold, colorful poster designs.

zones are cooler than the lowlands. Temperatures throughout the country average 26 °F (-3 °C) in January and 73 °F (23 °C) in July. The average annual *precipitation* (rain, snow, and other forms of moisture) totals 24 inches (61 centimeters).

Economy

Natural resources. Poland's most important natural resource is coal. One of the richest coal fields in the world lies in southern Poland. Poland also has deposits of copper, lead, salt, silver, sulfur, and zinc.

Farmland covers more than three-fifths of Poland. But much of the soil is of poor quality and must be fertilized. Forests cover about a fourth of the land.

Service industries are those economic activities that produce services, not goods. The leading employer among service industries in Poland is the community, social, and personal services group. It includes such economic activities as education, engineering, and health care. The second largest employer among Polish service industries is trade. Other service industries in-

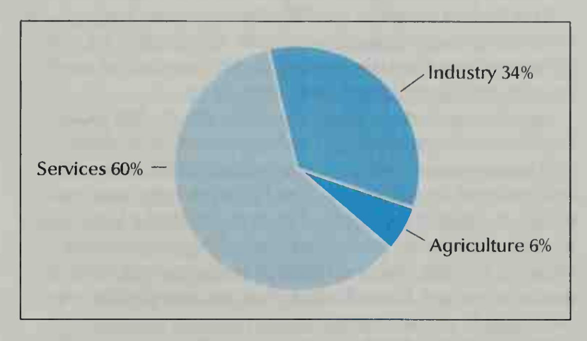
ude transportation and communication, government, nd finance and insurance.

Manufacturing and mining. The chief manufactured roducts of Poland include chemicals, food products, on and steel, machinery, ships, and textiles. Poland nks among the leading countries in the production of oal and silver.

Agriculture. Poland ranks among the world's leading roducers of potatoes and rye. Other important crops clude barley, sugar beets, and wheat. Farmers roughout Poland raise hogs. Cattle and sheep are ised mainly in the hilly regions of the south.

International trade. Poland's leading trading partners include the United Kingdom, France, Germany, aly, and Russia. Its chief exports include coal, food roducts, machinery, ships, and sulfur. Poland imports otton, food products, iron ore, machinery, natural gas, etroleum, wool, and other goods.

Transportation. Poland has an extensive system of oads, but railroads provide the chief means of transportation in Poland. The railroad network links most Polh cities and towns. The chief seaports in Poland are dańsk, Gdynia, and Szczecin. Polish Airlines (LOT), the ountry's only airline, operates both domestic and international flights. Poland's chief airport is at Warsaw.



Communication. Poland publishes about 55 daily ewspapers. The leading newspaper, which is pubshed in Warsaw, is *Gazeta Wyborcza*.

History

As early as 2000 B.C., the area that is now Poland was habited by the ancestors of Slavic tribes. During the .D. 800's, several Slavic tribes united under the Polanie, ne of the largest groups in the area.

The early Polish state. Members of the Piast family ecame Poland's first rulers. By the mid-900's, Prince lieszko I ruled over most of the land along the Vistula nd Oder rivers. His son, Bolesław I, conquered part of hat is now the Czech Republic and parts of what are ow Germany, Slovakia, and Ukraine. In 1025, Bolesław as crowned the first king of Poland. After his death later that year, Poland went through periods of warfare nd disunity. By the mid-1100's, the country had broken p into several sections, each ruled by a different noble.

Poland's gross domestic product

The gross domestic product (GDP) is the total value of goods and services produced within a country in a year. The GDP measures a nation's economic performance and can be used to compare the economic output and growth of countries. Poland's GDP was $135,623,000,000 in 1997.

Production and workers by economic activities

Retail trade is an important service industry in Poland and employs many people. The store shown here is part of a large shopping center built in Warsaw in the early 1990's.

economy, and encouraged cultural development.

The Polish empire. In 1386, Queen Jadwiga of Poland married Wladyslaw Jagiełło, the Grand Duke of Lithuania. Jagiełło ruled Poland and Lithuania, but each country remained largely self-governing.

Jagiellonian kings ruled Poland for nearly 200 years. Under their leadership, Poland expanded its territory and made important advances in its cultural, economic, and political development. The Polish empire reached its height during the 1500's, when it covered a large part of central and eastern Europe, including Belarus and Ukraine. In 1493, the first national parliament of Poland was established. Poland and Lithuania were united under a single parliament in 1569.

The decline of Poland. In spite of the advances of the Jagiellonian period, signs of strain developed in Poland after the mid-1500's. The monarchy began to lose power to the nobles, who dominated the parliament. After the death of the last Jagiellonian monarch in 1572, Polish kings were elected by the nobles. Some of the elected kings were foreigners, and these kings proved to be ineffective rulers.

Rivalries among the nobles weakened the Polish parliament, and costly wars ruined the economy. Poland lost much of its territory in Ukraine as a result of a rebellion that took place there in the mid-1600's. In 1655, Sweden won control over most of Poland's Baltic provinces. A series of wars with Turkey finally ended with a Polish victory at the Battle of Vienna in 1683.

The partitions. Poland's decline continued into the 1700's. In 1772, Austria, Prussia, and Russia took advantage of Poland's weakness and *partitioned* (divided) Polish territory among themselves. Austria seized land in southern Poland. Prussia took land located in western Poland. Russia took land in the east. As a result, Poland lost about a third of its territory and half its population.

After the first partition, the Polish government adopted a series of reform measures to stop the country's decay. In 1791, a new constitution restored the hereditary monarchy but also incorporated democratic procedures. However, the reforms came too late. In 1793, Prussia and Russia seized additional territory in eastern and western Poland. This second partition led to an uprising among Poles in 1794. Polish forces under Tadeusz Kościuszko fought Russian and Prussian troops but were defeated. Austria, Prussia, and Russia carried out the third partition of Poland in 1795, dividing what remained of the country among themselves. Poland no longer existed as a separate country.

After 1795, many Poles joined the French forces of Napoleon Bonaparte to fight against Austria and Prussia. In 1807, Napoleon gained control of Prussian Poland and made it into a Polish state called the Grand Duchy of Warsaw. But after Napoleon's final defeat in 1815, Poland was again divided among Austria, Prussia, and Russia. A small, self-governing Kingdom of Poland was established under Russian control.

The struggle against foreign rule. In 1830, Poles in the Kingdom of Poland rebelled against the Russians. But Russia crushed the revolt. Other unsuccessful revolts were launched against Austria and Prussia. After a second revolt in the Kingdom of Poland in 1863, Russia tried to destroy Polish culture by making Russian the official language there. After 1871, when Prussia formed the German Empire, Poles under Prussian control were forced to adopt the German language.

Poles under Austrian rule won some self-governmen[t] in the late 1800's. In the 1880's and 1890's, Polish politica[l] parties formed in all three parts of Poland. Leading politicians included Józef Piłsudski and Roman Dmowski.

World War I and independence. After the outbrea[k] of World War I in 1914, Piłsudski led Polish forces on the side of Austria against Russia. The Russians were driven out of most of Poland by 1915. In the following year Austria and Germany established a small Polish kingdom under their protection. In 1917, Dmowski formed the Polish National Committee in Paris to win Allied support for an independent Poland. After the Allied victory in 1918, an independent Polish republic was proclaimed. Piłsudski became the first chief of state.

Under the 1919 Treaty of Versailles, which officially ended military actions against Germany, Poland regained large amounts of territory from Germany. The port of Gdańsk was made the Free City of Danzig under supervision of the League of Nations. The return of land in Pomerania, a region along the Baltic coast, gave Poland access to the sea. In the east, Poland tried to reestablish the boundary it had with Russia before partition. This led to a war with Russia in 1919 and 1920. The 1921 Treaty of Riga represented a compromise. It established a border that gave Poland some of its prepartition land.

Rebuilding the Polish nation. The new Polish state faced many problems. Its leaders had to unify three regions that had been separate for more than 100 years. About a third of its population consisted of minority groups, some of whom resented Polish rule. In addition, the partitions and World War I had disrupted the country's economy. During the 1920's and 1930's, Poland slowly rebuilt its economy and developed uniform systems of government, transportation, and education.

The 1921 Constitution of Poland provided for a democratic government. But many political parties competed

1772 Austria, Prussia, and Russia partitioned Poland.

1793 Prussia and Russia partitioned Poland.

1795 The third partition of Poland ended its existence as a separate state.

1918 Poland proclaimed itself an independent republic.

1939 Germany and the U.S.S.R. invaded and partitioned Poland.

1945 A Communist-dominated government was formed, and Poland's present-day boundaries were established.

1989 Poland held its freest election since the Communists took control. Non-Communist candidates received great support i[n] the elections.

1990 Poland's Communist Party was dissolved, and the country created a democratic system of government.

1997 A new constitution went into effect.

1999 Poland became a member of the North Atlantic Treaty Organization (NATO), a military alliance of Western nations.

r power, and the government was unstable. In 1926, lsudski led a military overthrow of the government. He en took control. In 1935, Poland adopted a new constition that confirmed many of Piłsudski's unrestricted owers and limited the development of democracy. Piłdski died in 1935. But his successors continued the olicy of semi-authoritarian rule.

In the 1930's, Poland began to be threatened by the owing military strength of Germany and the Union of oviet Socialist Republics (U.S.S.R.). The U.S.S.R., also alled the Soviet Union, had been formed in 1922 under ussia's leadership, and it existed until 1991.

In 1939, German dictator Adolf Hitler demanded that anzig (Gdańsk in Polish) be given to Germany. He also emanded transportation rights across eastern Pomeraa. The Poles resisted Hitler's demands and formed an liance with Britain. Britain and France, which had gned an alliance pact with Poland in 1921, pledged to efend Poland if the country's independence was directthreatened.

World War II. In August 1939, Germany and the Sovi Union signed a treaty in which they secretly planned divide Poland between themselves. On September 1, ermany attacked Poland. Britain and France then deared war on Germany. The U.S.S.R. invaded Poland on eptember 17. The Poles fought bravely, but were deated within a month. Germany and the U.S.S.R. then dided Poland. In 1941, Germany attacked the U.S.S.R. and eized all of Poland.

Shortly after the fall of Poland, a Polish government-exile was formed in Paris. Later, it was moved to Lonon. Polish armed forces joined Allied forces in many ampaigns. In addition, an underground Home Army perated inside Poland against the Germans.

After the German attack against the U.S.S.R. in 1941, olish Communists formed an exile center in the U.S.S.R. oles under the command of the U.S.S.R. fought against ermany on the eastern front. The Communists also rmed their own small underground movement. In 942, they established the Polish Communist Party. Władysław Gomułka became the party leader in 1943.

In 1944, the Soviet Union's army invaded Poland and egan to drive out the Germans. Also in 1944, the Home rmy staged an uprising against the Germans in Waraw. But after two months of fighting, the Home Army ad to surrender. That same year, a Polish Committee of National Liberation was formed in Lublin. The U.S.S.R. recognized the committee, which consisted almost entirely of Communists, as the provisional government of Poland. At the 1945 Yalta Conference, the Allies agreed to recognize the committee after it was expanded to include representatives of the London government-in-exile and other non-Communist groups.

Poland suffered widespread death and destruction during the war. Much of Warsaw and other cities were destroyed. Millions of Poles, including most Polish Jews, were put into concentration camps when the U.S.S.R. and Germany occupied Poland. Between 1939 and 1945, over 6 million Poles died. About half were Jews.

Agreements reached at the end of the war shifted Poland's borders westward, and millions of Poles were resettled. The U.S.S.R. kept most of eastern Poland. In return, Poland received the German lands east of the Oder and Neisse rivers, including major industrial regions.

Communist rule was opposed by most Poles. But the Communists used police power and other methods to crush resistance. Communist-controlled elections in 1947 gave them a large majority in the new legislature. By 1948, Communist rule was firmly established.

In the late 1940's, the U.S.S.R. gained increasing influence over the Polish government. In 1949, a Soviet military officer, Konstantin Rokossovsky, was made Poland's defense minister. Polish Communists suspected of disloyalty to the Soviet Union were removed from power. They included Władysław Gomułka, who, as first secretary, held the most powerful post in Poland. He was removed from his post in 1948 and imprisoned in 1951.

In 1952, Poland adopted a constitution patterned after that of the U.S.S.R. The constitution established the country as a *people's republic.* In theory, the working people of Poland held all political power. However, the Communist Party actually controlled the government. Only a few other small parties were allowed to exist, and they supported the Communist Party policies.

The government took control of the economy. The country's Communist leaders established a system of government-owned industries. They developed new industrial regions around Kraków, Warsaw, and other cities. Many people moved from the rural areas to take jobs in the cities.

The Communists forced farmers to give up their land and join collective farms that were managed by the gov-

he first partition, in 1772, resulted in oland's losing about a third of its land to e neighboring countries of Austria, russia, and Russia.

In the second partition, in 1793, Russia took most of the regions of Lithuania and Ukraine in eastern Poland. Prussia took most of western Poland.

WORLD BOOK maps

In the third partition, in 1795, Austria, Prussia, and Russia occupied what remained of Poland. Poland ceased to exist as an independent nation.

ernment. However, many farmers resisted, and the collectivization program ended in the 1950's.

The government placed restrictions on religious practices. As part of an antireligion campaign, the Communists imprisoned Stefan Cardinal Wyszyński, who was the head of the Roman Catholic Church in Poland.

Antigovernment protests. During the 1950's, many Poles began to express discontent with government policies and resentment of domination by the U.S.S.R. In 1956, workers in Poznań and other cities staged antigovernment riots. Władysław Gomułka was then freed from prison and again became head of the Communist Party. He ended the forced take-over of farmland and eased the campaign against religion. Cardinal Wyszyński was released from prison, and defense minister Rokossovsky was dismissed.

In the 1960's, Polish intellectuals protested against government limits on freedom of expression, and new disputes erupted between the government and the Catholic Church. In 1970, strikes and riots broke out in Gdańsk and other cities. Thousands of Poles demanded better living conditions and economic and political reforms. After days of riots, Gomułka resigned, and Edward Gierek became the Communist Party leader.

Gierek's leadership brought better relations between the government and the Catholic Church. Although Poland remained a loyal ally of the Soviet Union, its government took steps during the 1970's to improve relations with non-Communist countries.

In 1978, Karol Cardinal Wojtyła, a Polish cardinal and the archbishop of Kraków, was elected pope of the Roman Catholic Church. He took the name of John Paul II. He became the first Polish pope in history and the first non-Italian pope since 1523. He called on Poland's government to allow greater freedom to its people.

Poland struggled with high prices and shortages of food and consumer goods. In 1976, Poles rioted after the government announced big increases in food prices. Government leaders then deferred the increases. Economic conditions worsened in the late 1970's.

During the summer of 1980, thousands of workers in Gdańsk and other cities went on strike. They demanded higher pay, free trade unions, and political reforms. Communist leaders promised to meet many of the demands. In September, the Central Committee forced Gierek to resign and elected Stanisław Kania to replace him. In November, the Polish government recognized Solidarity, an organization of free trade unions. This wa the first time a Communist country recognized a labor organization that was independent of the Communist Party. Lech Wałęsa headed Solidarity.

Economic problems, including food shortages, increased. In October 1981, the Central Committee made Kania resign and elected Wojciech Jaruzelski, an army general, head of the Communist Party.

Jaruzelski's government faced continuing economic problems and demands by the people for economic im provements and greater political freedom. In Decembe 1981, Jaruzelski imposed martial law. He suspended Sol idarity's activities and had Wałęsa and hundreds of union leaders held as prisoners. In October 1982, the government officially outlawed Solidarity. Wałęsa and some Solidarity members were released in late 1982. The remaining prisoners were released over the next several years. Jaruzelski's government formally ended martial law in July 1983. But many controls over the peo ple's freedom were retained.

Free elections. In 1989, the government reached an agreement with Solidarity that led to the legalization of the union and to changes in the structure of the govern ment. Under the agreement, an office of president with broad powers was created, and a new legislature was formed. An upper house, the Senate, was added to the Sejm, the lower house, to form the National Assembly.

The elections that were held in 1989 were the freest i Poland since the end of World War II. Non-Communist candidates were allowed to compete for all Senate seat and some seats in the Sejm. The remaining seats in the Sejm were reserved for members and allies of the Com munist Party.

Solidarity candidates won all the lower-house seats they contested and all but one of the upper-house seats After the elections, parliament elected Jaruzelski president and appointed Tadeusz Mazowiecki, a Solidarity leader, as prime minister. Mazowiecki became Poland's first non-Communist prime minister since World War II The new government began to end Communist control over the lives of the people.

Also in 1989, the government began a program to sel government-owned industries to private owners. Much progress was made in this program in the 1990's. In 1990, Poland's Communist Party was dissolved.

In 1918, Poland became an independent republic. Later, Austria, Germany, Lithuania, and Russia gave up large amounts of territory to Poland.

In 1939, at the beginning of World War II, Germany and the U.S.S.R. divided Poland almost in half. Poland again disappeared from the face of Europe.

WORLD BOOK map

In 1945, at the end of World War II, a new Poland was formed. Most of the lan was retaken from Germany. The U.S.S.R. kept most of the land it had taken in 1939

In June 1990, Solidarity split into several groups. One oup supported Mazowiecki, and another supported ałęsa. In November, Mazowiecki, Wałęsa, and Stanisw Tymiński ran in a presidential election. Mazowiecki iished third and then resigned as prime minister. ałęsa won a runoff election against Tymiński in Dember and became Poland's president. After the elecɪn, Wałęsa resigned as head of Solidarity.

Parliamentary elections were held in October 1991. iis time, all seats in the legislature were contested. The 89 system of reserving seats in the lower house for embers of specific parties was abolished. The Democatic Union, a party that formed out of Mazowiecki's anch of Solidarity, won the most seats in both the ejm and the Senate. But it was not able to form a stable palition because of the large number of parties that id won parliamentary seats.

By 1993, economic hardship brought on by the iange to a free-market economy discouraged many eople. In 1993 elections, the Democratic Left Alliance id the Polish Peasant Party won the most seats in parment. Both parties included many former Commusts. The parties formed a coalition government and ipported more economic reform. In 1995, Aleksander vaśniewski, a former Communist leader, was elected esident in a narrow victory over Wałęsa. Kwaśniewski med to continue the reforms and to make Poland a irt of Europe's economic and security organizations.

Recent developments. In 1997 elections, Solidarity on the most seats in parliament and defeated theforer Communists who had been in control. Solidarity rmed a new coalition government with the Freedom nion. Also in 1997, the country's new constitution went to effect. In 1999, Poland became a member of the orth Atlantic Treaty Organization (NATO), a military alınce of Western nations. In 2000, Kwaśniewski was reected president. In parliamentary elections in 2001, the Democratic Left Alliance won the most seats. The party formed a coalition government with the Peasant Party.

The hardy polar bear lives along the frozen shores and in the icy waters of the Arctic Ocean. Polar bears have a thick, white coat that blends in with the ice and snow. They swim strongly by paddling with their front legs and stretching their head forward.

Polar bear is a large, white bear of the North. Most polar bears live in regions where the mass of sea ice surrounding the North Pole breaks apart during the summer. They live chiefly along the northern coasts of Canada, Greenland, and Russia, and on islands of the Arctic Ocean. Polar bears also are found near the northern coast of Alaska. Polar bears hunt seals and other animals for food.

Body. A polar bear has a long body, neck, and head; short, furry ears; and sharp teeth. Adult male polar bears measure from 8 to 11 feet (2.4 to 3.4 meters) long. Some of them weigh more than 1,000 pounds (454 kilograms). Most adult female polar bears are about 6 feet (1.8 meters) long and weigh 400 to 500 pounds (181 to 227 kilograms).

Polar bears have dense, white fur. Their fur and thick layers of fat beneath their skin protect them from the bitter cold. Their white fur also serves as camouflage when hunting.

Polar bears have a keen sense of smell. They can smell food as much as 10 miles (16 kilometers) away and can sniff out seal dens that are covered by thick layers of snow and ice. Polar bears are also good climbers and excellent swimmers. On land, they can run for short bursts at speeds of up to 35 miles (56.3 kilometers) an hour.

Habits. Polar bears feed mainly on a small species of seal called the ringed seal. In the spring, polar bears hunt young seals by killing them at their dens. Later, seals are hunted at holes in the ice where they come up for air. After the ice breaks up, polar bears may surprise

Jerry Cooke, Animals Anima

A mother polar bear guards her cubs. At birth, the cubs weig only about $1\frac{1}{2}$ pounds (0.68 kilogram) and are completely helpless. Most cubs live with their mother for the first 2 years.

ıls resting on floating ice by swimming up and poun- g on them. Polar bears also eat sea birds, lemmings, ı, berries, and grasses.

Polar bears live in dens during the colder months. A egnant female will usually occupy a den from October April. She most often digs the den in a deep snow- nk on the side of a hill or valley. In late November or rly December, she gives birth to her young—usually n cubs. At birth, polar bears measure only about 10 hes (25.4 centimeters) long and weigh about 1 $\frac{1}{2}$ unds (0.68 kilogram). Most family groups of polar ars stay together for about two years. Wild polar ars may live up to 33 years and those in captivity may a bit longer.

Polar bears and people. Although polar bears hunt er animals, they rarely kill people. But people threat- the survival of polar bears. Hunters have killed many lar bears for their pelts. Today, there are only about 000 wild polar bears in the world. The United States, nada, and other nations have laws that protect polar ars from hunters. C. R. Harington

Scientific classification. Polar bears belong to the family Ur- ae. They are *Ursus maritimus.*

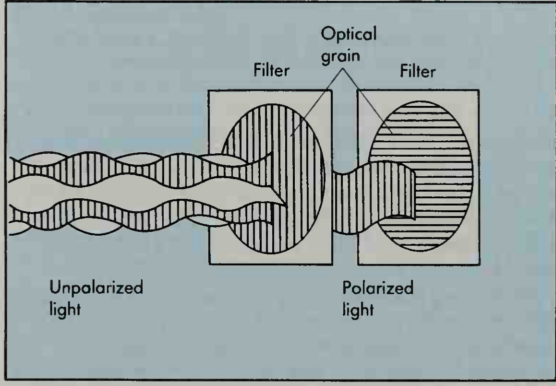
larization. See **Polarized light.**



larized light consists of light waves that have a nple, orderly arrangement. The waves of ordinary ht are arranged in a complex, disorderly manner. Or- nary light from the sun or a lamp is composed of dis- derly waves that vibrate in *all* directions perpendicu- to the light beam. But polarized light consists of derly waves that vibrate in only *one* direction. Because its orderly structure, polarized light can be used in ys in which ordinary light cannot. For example, the in- nal physical structure of many transparent materials be seen with the aid of polarized light. Light polariz- are powerful tools that are used in science, industry, d daily life.

How light is polarized. To understand polarization, nk of a light beam as a train of electromagnetic waves. e electromagnetic forces making up these waves vi- ate in a direction perpendicular to the path of the am. A rough example of these waves can be made by aching a rope to a wall and shaking the other end. A in of waves will move along the length of the rope. ch part of the rope will vibrate in all directions per- ndicular to its length. Waves that vibrate in this way called *transverse waves.* See **Waves** (Transverse ves; illustration).

Polarized light vibrates in a single direction perpen- ular to its path. Ordinary light can be polarized by ssing it through a special *light polarizing filter.* This fil- allows only the waves that vibrate in one perpendic- r direction to pass through. The structure of the light larizing filter prevents the passage of light waves that rate in other perpendicular directions. In scientific ms, the light polarizing filter allows the *components* rts) of the light waves that vibrate in one *vibration-di- tion* to pass through. The components of waves that rate in all other directions are held back. The light

How light is polarized

WORLD BOOK diagrams by Arthur Grebetz

Unpolarized light consists of waves that vibrate in all directions perpendicular to its path. A light polarizing filter allows only those waves that vibrate in a direction parallel to its optical grain to pass through, *top.* When the optical grain of a second filter is set at 90° to the grain of the first, the polarized light from the first filter is completely absorbed by the second, *bottom.*

that passes through the light polarizing filter is called *polarized light.*

All the vibrations that pass through a polarizing filter vibrate in one direction—a direction parallel to the opti- cal grain of the filter. The *optical grain* is the transmis- sion axis of the filter. Polarized light can pass completely through a second polarizing filter whose transmission axis is parallel to that of the first polarizing filter. But if the second polarizer is rotated like a wheel, it will grad- ually dim the light that comes through it. The second po- larizer will cut off the light entirely when its axis is "crossed" at 90° to the axis of the first polarizing filter. The dimming and cutting off occur because each polar- izing filter absorbs all components of the light that do not vibrate parallel to the filter's axis. As a result, the brightness of the light beam is gradually reduced as the transmission axis of the second polarizer cuts across the transmission axis of the first.

Many applications of polarized light are based on this phenomenon. For example, much of the light around us is already polarized. Mirrorlike reflections from shiny horizontal surfaces, such as pavement and water, con- sist largely of light that has been horizontally polarized

WORLD BOOK photo by Dan Miller

Without a polarizing filter, a photograph looks like a double exposure because the camera picks up reflections.

WORLD BOOK photo by Dan M

With a polarizing filter, a photograph is clear because the fi placed over the camera lens absorbs the reflections.

in the process of reflection. Polarized sunglasses, with their transmission axis set vertically, block the horizontally polarized light making up the bright reflections. Photographers use polarizing filters to cut down glare and reflections from shiny surfaces such as windows and water.

Polarizing materials. The most widely used light polarizers consist of thin plastic sheets. A typical plastic sheet contains millions of long, slender, carefully aligned chains of iodine molecules. Each of these chains acts like an individual polarizing filter. Sheet polarizers have greatly extended the uses of polarized light because of their low cost and convenient size. Edwin H. Land, inventor of the Polaroid Land camera, invented the first sheet polarizer in 1928, when he was 19 years old.

Some natural crystals, such as *tourmaline,* can polarize light. Tourmaline transmits the components that lie in one vibration-direction, and holds back others by absorbing them internally. Another natural polarizing crystal is *calcite,* or *Iceland spar.* It divides the light into two polarized beams that are at right angles to each other. *Nicol* prisms are cut from Iceland spar so that one of these beams is eliminated.

Uses of polarized light. Scientists have suggested that polarized glass be used for car headlights and windshields to prevent driving glare from the lights of approaching cars.

Scientists can study the structure of many transparent materials with the aid of crossed polarizing filters. Microscopes equipped with polarizers show many colorless crystals and biology specimens in brilliant color. A *polariscope,* an instrument equipped with polarizers, is used to find *strains* (weak spots) in glass objects such as eyeglasses and laboratory glassware. Chemists can tell the type and amount of sugar in a solution by using a *saccharimeter,* a type of polariscope. Special polarizing filters that produce circularly polarized light are used on radarscopes to trap unwanted reflections.

Pole. The earth is constantly *rotating* (spinning) on an imaginary line called an *axis.* The axis passes through t center of the earth and ends at either *pole.* The north end of the axis is the North Pole, 90 degrees north of t equator. The South Pole is the south end of the axis, 9 degrees south of the equator.

The term *pole* may be used to describe such a poin on any revolving sphere. For example, *celestial pole* refers to a point in the heavens around which the stars seem to revolve. A bright star located nearest to the ce lestial pole is called the *North Star,* or sometimes *polestar.*

In addition to the north and south geographic poles the earth has north and south magnetic poles, the farthest points on the earth in the directions of magnetic north and south. The north magnetic pole is currently cated near Ellef Ringnes Island in northern Canada, which is about 870 miles (1,400 kilometers) from the north geographic pole. The south magnetic pole is off the coast of Antarctica, which is about 1,710 miles (2,75 kilometers) from the south geographic pole.

In physics, the word *pole* means the point where magnetic lines of force appear to originate. Magnetic poles that are unlike attract one another, and like magnetic poles repel each other. Stephen S. Birdsall

See also **Earth** (Earth's size and shape); **Magnetism** (The magnetism of the earth); **North Pole; North Star; South Pole.**

Pole vault is an event in track and field competition i which athletes use a pole to propel their body over a crossbar set at a certain height. The equipment neede for pole-vaulting includes the pole, a crossbar, and tw upright standards to support the crossbar. The pole ca be made of any material. However, all good vaulters u poles made of fiberglass. The pole is from 12 to 17 $\frac{1}{2}$ fe (3.7 to 5.3 meters) in length. The fundamentals of pole-vaulting include (1) the grip, (2) the run, (3) the plant an take-off, (4) the swing, (5) the pull-up, and (6) clearing th bar.

The grip is important in pole-vaulting. The athlete ust position the hands properly and place them at the eal height on the pole. He or she places one hand 2 to feet (61 to 91 centimeters) below the other hand, and olds the pole parallel to the ground.

The run down the runway toward the crossbar is ade almost at top speed, but the vaulter controls the n carefully. Markers along the runway allow the ulter to gauge his or her stride and take-off position that the take-off is from the same foot and at the same ace in every vault. During the run, the vaulter keeps s or her eye fixed on the box that is set in the ground eneath the crossbar.

The plant and take-off. The vaulter *plants* (places) e end of the pole in the box. As the speed obtained own the runway is transformed into upward motion, e pole bends. As it straightens, it helps the vaulter rust upward.

The swing and pull-up. As the vaulter holds onto e rising pole and swings the body through the air, he she pulls the knees up toward the chest and then oots the feet up toward the bar. The swing and ll-up produce a handstand effect with the vaulter's est next to the crossbar.

Clearing the bar. While the vaulter is in the hand-and position, the feet start down on the other side of e crossbar. This position of the body is essential for aximum height. The vaulter then pushes the pole away it will not hit the crossbar and knock it down. As the ulter releases the pole, he or she turns the thumbs in-ard to help prevent the elbows from hitting the cross-r. Michael Takaha

For world championship figures in the pole vault, see e *tables* with the articles **Track and field** and **Olympic ames.**

olecat is a small mammal that belongs to the weasel mily. There are three species of polecats: (1) the Euro-ean polecat, found throughout Europe, (2) the steppe olecat, found in the plains of central Asia, and (3) the arbled polecat, found in the dry grasslands of southeastern Europe to western China. The North American skunks are often called polecats because their habits are similar to those of the European polecat.

Polecats prey mainly on mice, rats, and other rodents. They also feed on birds, eggs, rabbits, fish, reptiles, insects, amphibians, and fruit. Polecats are active mostly at night and rely on their sense of smell to locate food. They usually live in an underground burrow, which has a special section to store extra food.

Polecats live alone, except during the mating season or when the female is raising her young. Five to eight young are born about 40 days after mating. They leave their mother after three months. When frightened, polecats discharge a strong-smelling fluid from scent glands under the tail. A polecat also uses this fluid to mark its *territory*, the area it will defend against intrusion from other polecats.

A polecat has a long, slender body and short legs, which enable it to chase rodents in burrows. All three species have a "mask" of darker hair around their eyes. European polecats have dark outer fur, with lighter colored underfur showing through. Their fur is marketed under the name *fitch*. Male European polecats are 13 to 18 inches (33 to 46 centimeters) long, not including a tail of 4 to 7 inches (11 to 18 centimeters). As with all polecat species, females are smaller.

Steppe polecats are usually brown or yellowish, with a dark tail and legs. Males measure 14 to 22 inches (35 to 56 centimeters) long, not including a tail of 3 to 7 inches (8 to 18 centimeters). Marbled polecats have a reddish-brown back, with patches of white or yellow. Male marbled polecats are 11 to 15 inches (28 to 38 centimeters) long, with a tail that measures 6 to 9 inches (15 to 22 centimeters).

Scientific classification. Polecats belong to the family Mustelidae. The scientific name for the European polecat is *Mustela putorius*. The steppe polecat is *M. eversmanni*, and the marbled polecat is *Vormela peregusna*.

Patrol officer in squad car

Police

Police are government officers who enforce the law and maintain order. They work to prevent crime and to protect the lives and property of the people of a community. Policemen and policewomen serve their communities in many ways. They patrol streets to guard against crime and to assist people with various problems. Police officers direct traffic to keep it running smoothly and safely. The police are often called to settle quarrels, find lost people, and aid accident victims. During floods, fires, terrorist attacks, and other emergencies, they help provide assistance, transportation, and protection for victims.

The police form part of a nation's *criminal justice system,* which also includes courts and prisons. Police officers enforce *criminal law,* which covers murder, robbery, terrorism, and other crimes that threaten society. Police officers investigate such crimes and arrest suspected lawbreakers. They also testify in court trials.

Every nation in the world has a police system. In the United States, there are about 40,000 separate police agencies that operate under city, county, state, or fede al governments. In many countries, the national gover ment directs all police operations.

Police officers in the United States are often called *cops.* During the late 1800's, they were called *constab* The word cop may have come from the initials *c. o. p.,* which stood for *constable on patrol.* Some experts believe *cop* is short for *copper,* a word that referred to t copper badges worn by police officers.

George T. Felkenes, the contributor of this article, is Professor Emeritus of Criminal Justice at Claremont Graduate University and author of The Criminal Justice System.

Police activities

Patrol operations are the foundation of police work. Patrol officers are assigned *beats* (areas or routes) to cover on foot, in squad cars, or on motorcycles. In so cities, they patrol parks on horseback.

Patrol officers survey their beats repeatedly. Foot pa trol officers carry two-way pocket radios, and patrol c are equipped with larger two-way radios. Officers ma receive assignments over their radios to handle an au accident, investigate a reported crime, or settle a fami

argument. If necessary, they may call the police sta- on for assistance in handling an assignment. Patrol offi- ers are often assigned to control crowds at parades, irs, and other public events.

Police officers may arrest a person they see commit- ng a crime. They also may arrest a person if they have easonable cause to suspect that the person is commit- ng a crime or is about to commit one. But in some cas- s, police officers are required to get a court order alled a *warrant* before making an arrest.

Traffic operations. Traffic officers promote public afety on streets and highways. They direct traffic; pro- ect pedestrians; aid motorists; and enforce parking, peed, and other traffic laws. Traffic officers also investi- ate traffic accidents and enforce safety and license reg- lations for motor vehicles. Some police departments se helicopters to survey traffic.

Investigations of crimes are conducted by detec- ves, who are sometimes called *plainclothes officers* be- ause they do not wear uniforms. In some police depart- ients, the term *plainclothes officers* refers to members f the *vice squad.* The vice squad investigates cases that ivolve gambling, prostitution, or other illegal activities onsidered to be immoral.

Detectives work in various specialized fields that deal with such crimes as murder, robbery, or the illegal sale of drugs. In a murder case, detectives may start their investigation by searching for bloodstains, fingerprints, and weapons. They question any witnesses, suspects, or others who may have information about the crime.

Various technical units in a police department assist the detectives in an investigation. The *photography unit* takes pictures of the crime scene and the evidence. The *crime laboratory* collects and examines bloodstains,bullets, hair samples, fingerprints, weapons, and other evidence. Experts in the laboratory may perform chemical tests to identify any unknown substance connected with the crime. The detectives in charge of an investigation supervise the technical units involved. Later, the reports of the detectives and the technical units are used in court.

Criminal intelligence. Some police officers are assigned to gather *intelligence* (information) about the activities of suspected criminals. The women and men who work in the criminal intelligence division of a police department are sometimes called *undercover agents.* They gather information on such criminal operations as large-scale gambling, the illegal sale of drugs, and terrorist activity. The reports of intelligence officers are used in planning ways to fight criminal activities.

Juvenile work. Officers in the juvenile division of a police department handle cases involving youths accused of breaking the law. In most states of the United States, anyone under the age of 18 is considered a juvenile. Juvenile officers often refer young people to social agencies rather than bring criminal charges against them in a court. These officers try to help the young people and their parents with personal problems. They also investigate crimes that involve neglect or abuse of young children. The officers may testify in court to protect the rights of the youngsters. Also, juvenile officers often work with young people in community programs.

Records and communications. The records bureau of a police department keeps files on all reported crimes, investigations, and arrests, and on various police activities. Many police departments use computers to process and store these records.

The communications center is another important unit of a police department. Its *central dispatch office* receives calls for help or reports of crimes and sends officers to the scene. Many larger police agencies use computers in this operation. When a report of a crime or a call for help comes into the central dispatch office, the information is typed on the *terminal* of a computer. A terminal is an electronic keyboard that can both receive and send information. A dispatch officer reviews the problem and sends the information to one or more available patrol cars. The patrol officers receive the assignment over terminals in their cars.

Other activities. Large police agencies have various specialized units, including *search-and-rescue teams, hostage negotiating teams, bomb squads,* and *special weapons units.* Most members of such units work at other assignments until their special skills are needed. Some medium-sized and large police departments also have *data processing and research offices.*

Search-and-rescue teams try to find persons lost in forests, mountains, caves, or other out-of-the-way

places. Members of these teams are trained in rock climbing, mountain survival, and other skills. They often use helicopters and airplanes in rescue missions.

Hostage-negotiating teams handle cases in which criminals hold people captive. During some crimes, including bank robberies and airplane hijackings, the criminals may take innocent people as hostages. They threaten to injure or kill the hostages if certain demands are not met. Members of the hostage-negotiating team try to persuade the criminals to release the hostages without harm. Team members are skilled in psychology and personal relations.

Bomb squads respond to reports of bomb threats. They search the building or other place where a bomb supposedly has been planted. If they find a bomb, they try to prevent it from exploding or move it to a place where it cannot damage property or injure people.

Special weapons units handle dangerous situations involving armed criminals. Members of these units are skilled in the use of high-powered rifles and other weapons. They know how to surround and capture criminals with the least possible danger to others. Special weapons units are often called *S.W.A.T.* teams. Those letters stand for *S*pecial *W*eapons and *T*actics or *S*pecial *W*eapons *A*ttack *T*eam.

Data processing and research offices perform a variety of services. These offices may be staffed by police officers or by private citizens. Staff members compile crime statistics to help identify high-crime areas. They also prepare reports on personnel needs. In addition, they research new investigation techniques.

Computer crime specialists fight crimes committed with computers. Such crimes include embezzlement by bank employees and others with access to their employers' computer systems. Computer crime experts also may work to prevent fraud and other criminal activities on the global computer network known as the Internet.

Police in the United States

In the United States, police agencies operate under the city, county, state, and federal governments. Each agency is responsible only to its own division of government. Private police agencies are licensed by the states to provide certain types of police services.

City police. The size of a city police force depends on the size and needs of the community. New York City has the largest city police department in the United States—about 29,000 police officers. A small town may have a police force of only one or two officers.

City police are mainly responsible for enforcing the law in their own city. In some states, city police may exercise police powers in other communities only under special circumstances. In other states, city police may exercise police powers throughout the state. A few communities have combined their city and county police forces into a single *metropolitan police* force.

Some city police departments have specialized forces with certain limited powers. Such forces include airport police, housing police, park police, and transit police.

In most cities, the mayor appoints the head of the police department. This official may have the title of *chief, commissioner, director,* or *superintendent.* Other ranking police officers include *inspectors, lieutenant colonels, majors, captains, lieutenants,* and *sergeants.*

County police. The powers of a county police forc extend throughout the county. In some states, howeve these powers are restricted in towns and cities that ha their own force. A *sheriff,* elected by the people, is the chief law enforcement officer in most counties. In som states, the sheriff's department provides police service on a contract basis to cities and towns within the coun

The duties and powers of the sheriff's department vary from county to county. In some counties, the sher takes charge of prisoners in the county jails, attends se sions of the county court, and carries out court rulings in matters of *civil law.* Civil law covers such matters as business disputes and the transfer of property. In othe counties, the sheriff's department may also conduct fu scale police operations and provide training and techn cal services to city police.

State police. Every state but Hawaii has either a stat police force or a state highway patrol force. The powe of these forces vary from state to state. A commissione or superintendent chosen by the governor heads both types of agencies. Hawaii has only county police force:

State police enforce state laws. They also may coord nate police activities within the state and provide techr cal services and training programs to city and county police departments. State police officers are sometime called *troopers* because they were originally organize along military lines and often rode horses. Most state highway patrol forces have the primary duty of enforcing highway and motor vehicle regulations. Some also conduct full-scale police operations.

Federal law enforcement agencies include the Federal Bureau of Investigation (FBI). The FBI is the chi investigating branch of the U.S. Department of Justice. investigates federal crimes and handles cases involvin stolen money or property that has been taken across state borders. The FBI also operates the National Crim Information Center (NCIC) in Washington, D.C. The NC is a computerized information system that stores records on wanted persons and stolen property. Police de partments in every state are linked to the NCIC throug local terminals and may obtain information at any time

Nine other major federal law enforcement agencies also have full police powers. They are the Bureau of Al cohol, Tobacco, and Firearms; the Drug Enforcement Administration; the Immigration and Naturalization Se ice; the Internal Revenue Service; the Postal Inspectio Service; the U.S. Coast Guard; the U.S. Customs Servic the U.S. Marshals Service; and the U.S. Secret Service.

The Department of Justice also includes the Bureau Justice Statistics and the National Institute of Justice. These offices do not enforce laws, but they support po lice programs that aim to prevent and control crime. They do this mainly through research and analysis of various aspects of crime and the criminal justice syste

Private police agencies are licensed by the states perform limited types of police work. *Industrial securi police* guard factories and warehouses. *Campus polic* protect the people and property of colleges and unive sities. *Private investigative agencies* provide detective services to individuals and businesses.

Police around the world

In many countries, the national government directs the police system and maintains a national police forc

In Canada. Canada has national, provincial, and city olice forces. The Royal Canadian Mounted Police CMP) enforces federal laws throughout Canada. It rves as a provincial police force in all provinces ex- pt Ontario and Quebec, which have their own forces. ie RCMP is the only police force in the Yukon Territory id the Northwest Territories. The RCMP provides po- e services on a contract basis to about 175 cities.

Members of the RCMP are traditionally called iounties," though they now ride horses only in special eremonies. For their daily assignments, they travel in rs, snowmobiles, helicopters, and other vehicles. See oyal Canadian Mounted Police.

In other countries. In the United Kingdom, the po- e system is organized into about 50 large forces that e connected with local governments. These forces operate under the direction of the national government. The London Metropolitan Police serve Greater London except for an area that is called the City of London, which has its own force. The headquarters of the Metropolitan Police is called New Scotland Yard. The name *Scotland Yard* is often used to refer to the Criminal Investigation Department of the Metropolitan Police (see **Scotland Yard**).

Royal Canadian Mounted Police

ie Royal Canadian Mounted Police enforces federal laws oughout Canada. This officer is checking the driver's license a motorist she has stopped for a traffic violation.

In Australia, each of the six states and two mainland territories has a police force. Australia also has a national police force, the Commonwealth Police Force.

In France, the national law enforcement agency is the Sûreté Nationale. The Sûreté Nationale forms part of the Ministry of the Interior. Police officers called *gendarmes* serve as military police and provide police services in rural areas.

In Germany, the police are organized under the individual states. The states also maintain stand-by police who assist the state police when necessary.

In Russia, the Ministry of Internal Affairs (MVD) is in charge of providing general police services. It also provides border guards and investigates activities considered a threat to the security of the national government.

In China, a national police force called the People's Police is directed locally by provincial public security bureaus. These bureaus function under the Ministry of Public Security, an agency of the national government.

Interpol is an international organization of police forces from almost all countries. Its official name is the *Inter*national Criminal *Pol*ice Organization. Members of Interpol exchange information about international criminals and cooperate in fighting such international crimes as counterfeiting, smuggling, and illegal buying and selling of weapons. The headquarters of Interpol are in the city of Lyon in France.

History

In many ancient societies, the military forces served as police. In ancient Rome, for example, the military

Photoworld, FPG

Bobbies stand guard outside a royal wedding in London in 1923. British police were nicknamed *bobbies* after Sir Robert Peel, who founded the first modern type of police force in 1829.

legions of the rulers enforced the law. Augustus, who became emperor in 27 B.C., formed a nonmilitary police force called the *vigiles.* The vigiles were responsible for keeping the peace and fighting fires in Rome.

Early law enforcement in England. During the A.D. 800's, England developed a system of law enforcement based on citizen responsibility. The people of a community were divided into *tithings* (groups of 10 families), and each tithing was responsible for the conduct of its members. Males more than 16 years old stood watch duty. When a serious crime occurred, all able-bodied men joined in a *hue and cry* (chase of the suspect). Each *shire* (county) was headed by a *reeve* (chief). The word *sheriff* is a shortened form of *shire reeve.*

In 1750, Henry Fielding, a London *magistrate* (judge) and author, organized a group of law enforcement officers called the Bow Street Runners. These officers ran to the scene of a crime to capture the criminal and begin an investigation.

Sir Robert Peel, a British statesman, founded the London Metropolitan Police in 1829. The force was established along military lines, and its officers were carefully selected and trained. The public called the officers *bobbies,* after Sir Robert, and they still have that nickname. Peel is regarded as the father of modern police organizations.

Law and order in America. The American colonists established the English watch system in the towns and villages of New England. In many colonial areas, sheriffs and constables were responsible for keeping the peace.

Later, on the Western frontier, sheriffs and marshals enforced the law. But citizens sometimes formed groups of self-appointed law officers called *vigilantes* to capture and punish outlaws (see **Vigilante**). The Texas Rangers, band of mounted riflemen organized in the early 1800's were the first form of state police. They fought Indians, patrolled the Mexican border, and tracked down cattle rustlers and other outlaws. In 1905, Pennsylvania established the first state police force.

In 1845, New York City combined its separate day an night watches into a single city police force modeled a ter the London Metropolitan Police. Other U.S. cities formed similar police forces during the following year

Many early city police departments were poorly organized. Officers were underpaid and got little training In many communities, city leaders gained control of th police. They used the police in conducting their politic campaigns and for other personal purposes.

During the early 1900's, August Vollmer, the police chief of Berkeley, California, gained fame as a police re former. Vollmer brought about many changes in the po lice system. He urged reorganization of police departments, college education for police officers, and the us of scientific methods in police work.

Today, most medium-sized and large police departments hire officers through the civil service process (se **Civil service**). In this way, officers are not subject to po litical influence.

In the United States since the mid-1900's, riots ha broken out from time to time in a number of cities. In some of these uprisings, especially in the 1960's and 1970's, African Americans rioted in anger at their poor living conditions and few job opportunities. In other ca es, the rioters were college students who opposed var ous policies of the government or of their schools. In trying to control the rioters, the police were sometime charged with using unnecessary force. In later years, a number of riots were triggered by incidents in which the police were believed to have used excessive force dealing with individual members of minority groups. A a result of these events, hostility toward police officers sometimes has became widespread, especially among minorities. These groups have accused the police of treating them unfairly and giving them poor protection in their neighborhoods.

In an effort to improve their relations with citizens a to reduce crime, some police departments have devel oped or expanded community relations and crime pre vention programs. Police officers meet with neighborhood residents and civic organizations to discuss problems and explain police services. Neighborhood police teams have been established to bring the police into closer contact with neighborhood residents. Thes teams of police officers patrol specific neighborhoods and investigate all crimes there. In some areas, special juvenile gang units focus on preventing gang member ship, identifying gang members, and stopping illegal gang activities.

The police also encourage citizens to help fight crim In some communities, citizen volunteers organize patrols to guard housing projects and homes. Other com munities organize Neighborhood Watch programs in which residents report any suspicious activities in thei neighborhood to the police. Many police departments have employed more nonpolice personnel to handle such police duties as traffic control and dispatching. Th use of these employees has enabled the departments

sign more police officers to the fight against crime.

Since 1970, the number of women entering police ork has increased substantially. Also, police depart- ents now assign female officers to patrol duty and ime investigation. Formerly, female police officers rved chiefly as office workers, as juvenile officers, and guards in women's prisons. Police agencies also have ade more of an effort to hire more members of minor- groups as police officers.

Investigations of several city police departments since 70 have revealed cases of police corruption. Some of- ers have been found guilty of taking bribes and com- itting other crimes. As a result of these investigations, lice leaders have stressed the need to maintain high andards in hiring recruits, to provide the best possible ining for officers, and to promote professional in- grity throughout the police department.

Careers

Police work offers many opportunities to help people d to serve a community. However, it can be danger- s and sometimes requires working irregular hours.

The requirements for applicants for positions with po- e agencies vary among the cities and states. The mini- um age requirement for police work varies from 18 to . Some police agencies have a maximum entry-level e of 35. Candidates must pass a thorough physical ex- nination, be honest and even-tempered, and have od judgment and a sense of responsibility. Most po- e agencies require that candidates obtain a high hool education, and many require some college train- g. Applicants must pass a written examination. Some lice agencies require officers to live and work in the me community.

Recruits attend police academies connected with the ty, county, or state police agencies. Training periods ry from 6 weeks to a year. Recruits study such subjects law, psychology, sociology, traffic control, weapons, d rules of evidence. Many police agencies also re- ire recruits to spend a period with a field training offi- r in a squad car before going on duty alone.

Numerous police agencies have continuing education ograms to keep officers informed of changes in the w and new techniques in police work. Some agencies fer the benefit of paying the cost of a college educa- n for officers who wish to acquire this schooling.

Police dog is the common but incorrect name for the German shepherd dog. This name is not correct because many other breeds of dogs, such as the Airedale terrier and Doberman pinscher, receive special training to help the police. Such dogs receive special training in tracking down criminals, in guard duty, and in other types of work. See also **German shepherd dog.**

Police state is any nation or other political unit in which the government allows its law enforcement agencies to maintain order through terror. In such a state, the police are not subject to laws or other restraints that would ordinarily limit their actions in a constitutional democracy. The police can spy on anyone without regard for privacy. They can also arrest, imprison, execute, or exile people for any reason.

In ancient times, the Greek city-state of Sparta had the most developed form of police state. During the 1900's, fascist and Communist countries often used police state tactics. Alexander J. Groth

See also **Secret police.**

Polio. See **Poliomyelitis.**

Poliomyelitis, *POH lee oh MY uh LY tihs,* also called *polio* or *infantile paralysis,* is a serious infection caused by a virus. In the past, epidemics of polio were common and were greatly feared because the disease left many patients paralyzed for life. In the 1950's, however, a vaccine against the disease was introduced. Since then, polio has been nearly eliminated in developed countries.

Kinds of poliomyelitis. A polio virus may attack the nerve cells of the brain and spinal cord, causing paralysis. However, infection by a polio virus does not always result in severe illness. Some patients show only mild symptoms, such as fever, headache, sore throat, and vomiting. Symptoms may disappear after about a day.

Severe polio attacks begin with the same symptoms as the mild attacks. The symptoms, however, do not di appear. Stiffness of the neck and back develops. The muscles become weak, and movement is difficult. Pain may occur in the back and legs, especially when these parts are stretched or straightened. If paralysis develo the person may not be able to stand or walk.

Most people who develop polio do not become pe manently paralyzed. Paralysis can occur in many degrees and combinations. *Spinal poliomyelitis* is probal the most common form of polio. It occurs when polio viruses attack the nerve cells that control the muscles the legs, arms, trunk, diaphragm, abdomen, and pelvis *Bulbar paralysis* is the most serious form of the diseas It results from damage to the nerve cells of the brain stem. Some of these nerves control the muscles for swallowing and for moving the eyes, tongue, face, anc neck. The nerves that control breathing and the circula tion of body fluids may also be affected.

Some polio patients suffer new symptoms about 30 years or more after the initial attack. These symptoms clude fatigue, muscle weakness, pain in the joints, and difficulty in breathing. Physicians are not sure what ca es this condition, called *post-polio syndrome.*

Cause of poliomyelitis. There are three viruses tha cause polio. They are called types I, II, and III.

Polio viruses can grow only in living cells. They get into the body through the nose and mouth and are ca ried to the intestines. Then they travel along the nerve fibers or are carried by the blood to the central nervo system. There, they enter a nerve cell and multiply so rapidly that they damage or kill the cell. Paralysis resul when many cells are destroyed. Scientists do not kno why epidemics occur. People who become infected b the virus do not always get polio. The virus has been found in apparently healthy people, especially during epidemics.

Prevention of poliomyelitis. There are two polio vaccines, and both protect against all three types of po lio viruses. The first vaccine, developed by the Americ researcher Jonas E. Salk, is given by means of injectior It was declared safe and effective in 1955. The other po lio vaccine was developed by Albert B. Sabin, another American researcher. It was approved for use in the United States in 1961. The Sabin vaccine is an *oral vaccine*—that is, it can be taken by mouth.

Children should be vaccinated against polio early in life. A vaccine is typically given in four doses—at 2 months of age, 4 months, 15 months, and 4 to 6 years age. The United States Centers for Disease Control an Prevention recommends two doses of injectable vacci followed by two doses of the oral form. When used fo all four doses, the oral form can, in extremely rare cas cause paralytic polio. However, the agency also consid ers four doses of either vaccine alone acceptable.

Treatment of poliomyelitis. No drug has yet been found that can kill the polio virus or control its spread the body. But the degree of recovery often depends o immediate medical attention and good nursing care.

Complete rest in bed is perhaps the most importan treatment. Doctors believe that fatigue may make the disease more severe. They use simple treatments, suc as hot, moist bandages, to relieve pain. After the fever

March of Dimes Birth Defects Foundation

Polio was one of the most feared diseases until an effective vaccine was found in 1955. This photo from the 1950's shows a polio patient learning to walk with crutches and leg braces.

es down, physical therapists may gently move the patnt's limbs to prevent deformities and painful tighteni of the muscles. Later, more intensive exercises help sengthen and retrain the muscles. Even extensively palyzed patients can often develop enough movement tarry on many activities. Less severely paralyzed peop usually resume most of their previous activities. Sne may need splints, braces, or crutches.

When breathing muscles are paralyzed, doctors may u a mechanical device such as a respirator to help the pient breathe. About two-thirds of such patients recove heir natural breathing. Marianne Schuelein

Plish Corridor was a narrow strip of territory taken fm Germany and granted to Poland after Germany's deat in World War I (1914-1918). The Treaty of Verslles, which officially ended the war with Germany, estlished the corridor in 1919 to give Poland direct accs to the Baltic Sea. The area of the corridor was once pt of a Polish region called Pomerelia.

Prussia gained the territory in 1772. The region came uler German control when Prussia became a German se in 1871. The largely agricultural region included tl towns Bydgoszcz, Grudziadz, and Toruń and the seapt Gdynia.

The corridor separated the East Prussia area of Germny from the rest of Germany. About half the people in tl region spoke German, and Germany and Poland cne to dispute ownership of the territory. In 1939, Germy regained control of the corridor. The corridor and h of East Prussia became part of Poland in 1945, after Vrld War II ended. Christoph M. Kimmich

WORLD BOOK map

Lation of the Polish Corridor

Pish lowland sheepdog is a breed of dog develod in Poland to herd sheep. It stands 17 to 20 inches (o 51 centimeters) tall at the shoulders and weighs fn 35 to 50 pounds (16 to 23 kilograms). The dog originated in northeastern Poland, possibly as early as the A.D. 1200's.

This breed has a strong, muscular body with a broad neck and large legs. Its hair grows long and thick, especially on its forehead, cheeks, and chin. The dog's coloring varies from individual to individual. Common color patterns include white with black, gray, or sandy patches; and gray with white or chocolate brown patches.

Polish lowland sheepdogs nearly became extinct during World War II (1939-1945). But today, people throughout the world own these dogs as pets and as herding dogs. Polish lowland sheepdogs can make loyal, intelligent companions.

Critically reviewed by the American Polish Lowland Sheepdog Club

Politburo, *puh LIHT BYUR oh,* or *PAHL iht BYOOR oh,* was the political bureau of the Central Committee that controlled the Communist Party of the Soviet Union from 1919 to 1991. V. I. Lenin, the country's first leader, set up the Politburo. Before 1990, the Politburo included the most powerful members of the party, and all important decisions in the Soviet government needed the Politburo's approval. But in 1990, the Politburo's power was greatly reduced when its role was limited to the development of party policy.

In August 1991, several Communist officials failed in an attempt to overthrow Soviet president Mikhail Gorbachev and take control of the government. After the attempt, the Soviet parliament suspended all Communist Party activities, including those of the Politburo. In December 1991, the Soviet Union broke up into a number of independent states. The name *Politburo* also is used for similar groups in other Communist countries.

Stuart D. Goldman

See also **Union of Soviet Socialist Republics** (Government); **China** (The Communist Party).

Political action committee is a group set up by a labor union, corporation, or other organization to contribute money to candidates for federal and state offices in the United States. Political action committees, often called *PAC's,* are formed largely because U.S. law forbids certain organizations to make contributions directly to candidates. PAC's get their money from individuals, in most cases from members of the group that formed the PAC. The first PAC's were established in the 1940's.

Federal law and some state laws limit the money a PAC may contribute to each candidate in an election. But the contributions may be repeated for each election, whether it is a primary or a general election. A PAC may also donate unlimited amounts to a political party.

Many people think PAC's have too much influence in American politics. They say that to raise campaign funds, officeholders may give more attention to issues that concern PAC's than to those that concern ordinary citizens. Also, PAC's donate mostly to candidates seeking reelection. Many people therefore believe PAC's reduce the competitiveness of elections by making it harder for challengers to win. Defenders of PAC's say they help citizens exercise their right to support political candidates and to communicate their concerns to public officials.

Bruce I. Oppenheimer

AP/Wide W

At a national political convention, delegates nominate their party's candidates for president and vice president. This crowd of delegates, lobbyists, and supporters celebrates the nomination of Texas Governor George W. Bush at the Republican Party convention in Philadelphia in 2000.

Political convention is a gathering at which major political parties in the United States formally nominate their candidates for president and vice president. At one time, the conventions actually selected, as well as formally nominated, the party's candidates. Today, however, the presidential nominees of the major parties are normally determined before the convention takes place. Nonetheless, the conventions of the Democratic and Republican parties—the two major political parties—play an important role in the U.S. presidential election process. The conventions allow the party to unify around its nominees. Equally important, the conventions provide wide public exposure for the party's candidates and goals. A successful convention can dramatically boost the public's support for the party and its candidates.

The Democratic and Republican national conventions are four-day events that take place every four years. The two conventions are held at separate times during the summer of each presidential election year. They are typically held in separate cities, and in different cities from year to year.

Huge crowds gather at each convention. The people in attendance include thousands of party delegates, who nominate a candidate they hope can win the presidential election the following November. An even larger number of magazine, newspaper, radio, and television reporters come to the convention. They provide coverage of the gathering for millions of voters throughout the nation. Many other people attend conventions, including *lobbyists* (representatives of interest groups), people who contribute money to the party or its candidates, and alternate delegates.

The first national political conventions in the United States assembled in the early 1830's. The presidential candidate was both selected and nominated at the convention until the mid-1900's. Today, the candidate is normally selected before the convention in a series of state elections and other contests. These contests determine the number of supporters each candidate will have at the convention as delegates. The candidate with the most delegates is formally nominated at the conventio The delegates then nominate a vice presidential candi date, who normally has been hand-picked by the pres dential candidate.

Other business is also handled at the convention. Fo example, the party adopts a *platform*—a statement of i goals and principles in the presidential campaign. The platform is designed to win votes for the presidential and vice presidential nominees, and for party candidates who are running for other political offices in the same election year.

Political conventions are lively events. Delegates su port their choice for president and vice president by waving banners and cheering wildly. Parades, parties, and other celebrations promote the political party an its nominees. On the last day of the convention, the presidential and vice presidential nominees give speeches that launch the party's election campaign. Th speeches are broadcast on TV throughout the countr

Preconvention activities

The process of nominating a presidential candidate begins months before the convention. The most impo tant step in the process is the selection of convention delegates. At the convention, each delegate votes for presidential candidate. The candidate who gets a maj ty of the delegate votes wins the party's nomination.

Delegate selection takes place in elections and ot er state contests that occur during the late winter and spring of each presidential election year. Washington D.C., Puerto Rico, and the Virgin Islands and other U.S territories also send delegates to the conventions.

The national committee of each party decides how many delegates each state may send to the conventio The number is based on the party's strength in the sta in recent elections. Thousands of delegates attend ea

›nvention, but exact numbers vary from year to year.
The method of choosing people to run as delegate ındidates is different in different states. In many states, ese candidates are chosen by the state party organiza- ›n, by the presidential campaign organizations, or by ass meetings of supporters of a presidential candi- ıte.

There are two main methods of choosing which dele- ıte candidates will attend the convention as delegates. ıey are (1) the *primary election system* and (2) the *cau- ıs-convention system.* Some states allow each party to ıoose which of the two systems it will use.

Most states require both parties to use the primary ection system. As a result, primary elections deter- ine more than two-thirds of all convention delegates.

Some states hold a *delegate primary,* in which voters ect the delegates. In most delegate primaries, the ımes of the delegate candidate and the presidential ındidate whom the delegate supports are printed to- ›ther on the ballot. In this way, voters know which del- ןate candidate supports which presidential candidate.

Other states hold a *candidate primary,* in which only e names of the presidential candidates appear on the ıllot. The number of votes each candidate receives in e primary determines the number of delegates he or ıe is allowed to send to the national convention.

The caucus-convention system was once the main ethod of selecting delegates to national conventions. ›day, less than one-third of all delegates are chosen in is way. The caucus-convention process begins with cal meetings called *caucuses.* At each meeting, dele- ıtes are chosen to attend a convention that covers a rger region, such as a county. This convention, in turn, lects delegates to a state convention, where the state's ıtional convention delegates are then chosen.

The caucus-convention process may begin with either two types of caucuses—*party caucuses* or *participa- ıry caucuses.* In a party caucus, the delegates sent to e regional convention are chosen by local party offi- ıls. In a participatory caucus, anyone who attends the ucus can take part in choosing the delegates.

Most states do not require individual delegates to ıte for the candidates the delegates have pledged to pport. But delegates rarely change their vote unless eir candidate drops out of the race.

Certain primaries and caucuses are more influential an others in determining who the presidential nomi- ıe will be. The early contests provide the first indica- ıns of which candidates may have a chance to win the ›mination. Candidates who do not win support in the rly contests are unlikely to raise campaign funds, ther campaign workers, or attract media attention. ıese candidates often drop out of the presidential race rly. The Iowa caucuses and the New Hampshire pri- ıry are examples of important early delegate contests.

The large states account for the most delegate votes each party's convention. As a result, the candidates re- ıining after early contests try especially hard to win tes in big states, such as California and Texas.

Organizing the convention is done by the party's tional committee. The committee chooses a perma- nt chairperson for the convention. It also designates a rson to kick off the convention with a rousing speech lled the *keynote address.* Members of Congress or other important party members usually are chosen for these positions. The committee also picks a convention site.

Much of the convention's official business is carried out by special committees. Most of the committees consist of delegates and other party members, including some elected government officials.

The special committees meet in the months before the convention. One committee prepares a report that establishes procedures for the convention, and another makes sure the state delegate contests have conformed to party rules. Yet another committee drafts a party platform.

Convention activities

The main purpose of a national convention is to nominate candidates for President and Vice President. But the convention also serves other purposes. Today, one of its most important functions is to present the party's platform and candidates to the nation's voters. To reach the voters, the party encourages television, newspaper, and other reporters to cover key events at the convention.

Introducing the campaign. Much of a national convention of the Democratic or Republican parties is devoted to speeches. These speeches include the keynote address. This speech, made by an important party member, sets out themes for the presidential campaign. It is also intended to inspire party members for the hard work needed to win the November election.

The presidential candidates who will not receive the party's nomination often deliver speeches. In most cases, they use their speeches to announce their support for the person who will become the nominee.

Also at the convention, the special convention committees present their reports for adoption by the convention delegates. Most reports are drafted before the convention and do not change once it begins. But some reports are adopted only after debate. General party reaction to the reports can influence the presidential race. For example, the report that presents the party's platform must appeal to a wide range of voters—as well as to party members. Disagreement on the platform at the convention may reveal a lack of party unity and thus make the party and its nominees less attractive to the nation's voters.

Making nominations. The presidential nomination is one of the highlights of the convention. Delegates officially recommend the nomination of candidates in *nominating speeches,* in which the speaker praises the accomplishments of the candidate. Each speech may build to a climax that triggers a massive demonstration in the convention hall. Delegates and other supporters of the candidate parade, wave banners, throw confetti, and cheer.

The *roll call* begins after all nominating speeches have been made. In the roll call, each state and territory casts a ballot that indicates how many of its delegate votes it is awarding to each candidate. The candidate who gets a majority of the votes of all the delegates at the convention formally becomes the party's nominee.

If no candidate receives a majority, more ballots would be cast until enough delegates switch their votes to give one candidate a majority. However, a second ballot has not been required at any Democratic or Republi-

can national convention since the early 1950's.

To nominate a candidate for Vice President, the party uses the same procedure that it used for the presidential nomination. The likely nominee for President normally chooses the vice presidential nominee before the convention begins. The delegates then approve the choice at the convention.

The nominees for Vice President and President make *acceptance speeches* near the end of the convention. These speeches are viewed on television by millions of people. The speeches outline the issues that will be emphasized during the campaign and are designed to win the confidence of voters. With their speeches, the nominees also try to rally the enthusiasm of party members who may have supported other candidates during the nominating campaign.

Other convention activities. Numerous other activities also take place at a national convention. For example, state party leaders attend the convention to discuss issues affecting the party in their state. Also, many of the party's candidates for election to Congress or to state or local offices campaign at the convention. Lobbyists attend the convention to try to influence delegates and party leaders or to use news coverage of the convention to further their causes.

Attracting publicity. National news coverage of the presidential candidate and the party has become a major goal of the organizers of political conventions. Both major parties rely on newspaper articles, television stories, and other press coverage to generate public support for their nominees.

All national conventions of the Democratic and Republican parties have been televised since 1952. The parties often schedule convention events to occur at peak TV viewing hours.

Measuring convention success. A convention's success was once measured chiefly by how well the convention promoted party unity. The convention was judged successful if it ended with party members from the various states supporting a single presidential candidate.

Today, however, the success of a convention is more often measured in terms of how much the convention contributes to the public image of the nominee. The party compares opinion polls taken before and after the convention to determine how the convention has affected the nominee's public approval rating. Because of media coverage of the convention, the nominee's rating almost always rises. But the extent of this rise can vary a great deal from convention to convention. A large upward "bounce" is the sign of a successful convention.

The history of national conventions

The writers of the Constitution of the United States did not outline a procedure for nominating a President. Until the early 1830's, a party's supporters in Congress or in state legislatures usually nominated the party's candidate for President.

The Anti-Masonic Party held the first national nominating convention in September 1831. The first convention that closely resembled today's gatherings was that of the Democratic-Republican Party in 1832. Soon, the convention became the established procedure in the United States for nominating presidential candidates.

The changing role of conventions. Until the mid-1950's, almost all presidential nominees were not only formally nominated at the convention, but they also fought there for the support required to win the nomination. Usually, strong candidates assembled some support before the convention. Then, at the convention, they competed with one another to win a majority of the delegates' votes. Party leaders often had significant influence in maneuvering the votes of the delegates. At many conventions, multiple ballots were needed to reach a majority. In 1924, the Democrats took 103 ballots to nominate John W. Davis—the largest number of ballots ever needed at a Democratic or Republican presidential convention.

By the mid-1950's, however, delegate majorities had begun to form before the convention. The last time a major party had to go to a second ballot was in 1952, when the Democrats needed three ballots to nominate Adlai E. Stevenson.

Various factors contributed to this change. For example, the ability of party bosses to influence the nomination had diminished because of new laws on delegate selection in the early 1900's. This legislation included several state laws that required the parties to select their convention delegates in primary elections.

As a result of these and other changes, candidates increasingly turned to campaigning among voters for support. The spread of TV after 1945 helped these candidates achieve national recognition and aided the formation of earlier and earlier nominating majorities.

Further reforms of the convention system took place soon after the 1968 Democratic convention. Many people viewing the convention, in which Hubert H. Humphrey won the nomination, disliked the political maneuvering they saw on the convention floor. Consequently, the Democrats appointed a commission to reform their rules for selecting convention delegates.

One result of the reforms was greater representation of minority groups and women among the delegates. The reforms also resulted in many states adopting laws that required the use of primary elections by both Republicans and Democrats. Although primaries had appeared in the early 1900's, they did not become the main method of delegate selection until after 1968.

Other types of conventions

State and local party conventions may be held to select party leaders, adopt local and state party platforms, or endorse nonpresidential candidates in primary elections. In addition, the constitutions of most states provide for a constitutional convention, often called a *con con.* The purpose of such a convention is to rewrite or revise the state constitution. The people of the state elect the con-con delegates. In most states, the people must approve the new or revised constitution before it can take effect. Byron E. Shafer

A olitical party works to gain or maintain control of a government. One way political parties su ort themselves is by raising money at fund-raising dinners, such as the one shown above.

Political party

P itical party is an organized group of people who c trol or seek to control a government. In democratic c ntries, political parties compete against one another in lections to keep or gain control of a government. In th United States and Canada, political parties are active o he national, state or provincial, and local levels.

olitical parties are absolutely necessary to demo- cr ic government. Most modern democracies are *rep- re ntative* democracies. That is, the people elect repre- se atives to act as their agents in making and enforcing la . In a representative democracy, some means is n ded for nominating candidates for public office and fo electing issues for public debate. Political parties p orm these functions. At election time, the people v into office the candidates of their choice. Political p ies are voluntary organizations and want as many m bers as possible. Some of these parties have rules a membership dues. Others have practically no rules a require no dues.

lost dictatorships allow only one political party—the p y that controls the government. That party also ti ly controls who may run for election.

Party functions

democratic countries, political parties perform sev- e important tasks. (1) They select candidates to run for p lic office. (2) They help organize the government. (3) T provide opposition to the party in power. (4) They ra funds to conduct election campaigns. Other func- ti of parties in democratic countries include inform- in voters about public affairs and about problems that n d government action. In one-party nations, the chief fu tions of political parties are to select candidates for office and organize the government.

Selecting candidates. In one-party nations, the candidates the party selects to run for office automatically win election because they have no opposition. In China, for example, the Communist Party—the only party allowed—chooses the candidates for office.

In nations that have two or more parties, each party selects candidates for the various public offices. The voters then decide which candidates among the parties win office. Party leaders try to select candidates who have voter appeal and experience for the office.

During the early history of the United States, party leaders selected candidates for office in meetings called *caucuses.* But the caucus system became unpopular because it gave other party members little voice in the selection of candidates. In addition, one person or a small group of persons sometimes gained control of a caucus and used it for private gain. See **Caucus.**

By about 1840, the *convention system* for nominating candidates was in general use. Under this system, party members chose delegates to represent them at nominating conventions. But party bosses and *political machines* (organizations within a party) gained control of many conventions. Many delegates voted the way they were told or paid to vote. Today, conventions are held in only a few states to make some nominations for state and local offices and to discuss party affairs. The two major U.S. political parties—the Democratic and Republican parties—still hold a national convention every four years to officially nominate candidates for President and Vice President. See **Political convention.**

During the early 1900's, many states began to replace the convention system with primary elections to select candidates for office. The aim was to reduce party control in the selection of candidates. Today, all states hold either *open* or *closed* primary elections for state offices. In an open primary, each voter receives the ballots of all parties holding primaries. In the voting booth, the voter selects which ballot to use. In a closed primary, voters receive only the ballot of the party to which they belong. In recent years, the Republican and Democratic parties

arles O. Jones, the contributor of this article, is Glenn B. an leone Orr Hawkins Professor of Political Science at the U ersity of Wisconsin-Madison.

have relied on primary elections—and, in some states, caucuses—to select their presidential candidates. The parties then formally nominate the candidates at their national conventions. See **Primary election.**

Organizing the government is a major function of political parties. But how the parties do this depends on the government's established structure and on how the powers of government are divided.

Unitary and federal systems. In countries that have a *unitary* system of government, such as France, Italy, and the United Kingdom, the central government has most governmental powers, including control over local governments. In countries that have a *federal* system of government, such as Canada and the United States, the powers of government are divided between the central government and the state or provincial governments (see **Government** [Systems of government]). The political parties in countries with a unitary system concentrate on gaining control of and organizing the central government. The parties are thus basically national in their activities and are so organized. The political parties in countries with a federal system try to gain power to organize both the central government and the state or provincial governments. The parties are thus both national and state in their activities and organization.

The presidential system. In the United States, the Constitution provides for the separation of powers among the executive, legislative, and judicial branches. The President, therefore, is not a member of Congress, nor are the Cabinet members. The President is elected by the people through the Electoral College and may be of a different political party than the party that controls Congress. Often, the President is forced to rely on leaders from both parties to get programs passed. Under the presidential system, Congress may refuse to pass legislation the President wants. On the other hand, the President may *veto* (reject) legislation passed by Congress—and Congress seldom overrides a veto.

The President serves a four-year term. The President has to deal with a House of Representatives whose total membership is elected every two years and with a Senate in which a third of the members face election every two years. These staggered elections make for shifting alliances and may increase or decrease support for th President's policies. The *bicameral* division of Congre into two independent bodies—the House of Represer tives and the Senate—also complicates the President's role. Traditionally, each body jealously guards its pow ers against executive interference.

The parliamentary system. In such parliamentary d mocracies as the United Kingdom, the head of the go ernment —the prime minister—faces fewer problems organizing the government. The prime minister must a member of Parliament and usually also is leader of t majority party in the House of Commons. The prime minister usually chooses a Cabinet from leaders of th majority party who are members of Parliament.

In the United Kingdom, the prime minister and Cab net thus have both executive and legislative authority. They are members of the legislature and responsible it. If the prime minister's program fails to win parliam tary support, the opposition party may demand an ele tion. This election is called for by the government but must occur within five years of the previous election. The people will vote either to keep the present gover ment in power or to give the opposition party the op portunity to form a new government.

Organizing the U.S. Congress. The Democratic and Republican parties organize their members in Congr according to the established structure of the House o Representatives and the Senate. At the beginning of each new session of Congress, both parties in the House and the Senate hold meetings to elect various ficers and committee members. In the House, each p nominates a candidate for Speaker, the body's presid officer. But most representatives vote for their party's candidate, and so the majority party actually chooses Speaker (see **Speaker**). In the Senate, the Vice Presid of the United States presides. The majority party elec president *pro tempore* (temporary) to preside in the a sence of the Vice President.

Each party in the House and Senate also elects a *fl leader* and a *whip.* The floor leaders direct their party activities during debates on proposed legislation. Th whips help the floor leaders by letting them know ho party members feel about bills coming up for vote. T

Important political parties of the United States

This chart shows the time spans of some of the important political parties of the United States. A question mark means the date is disputed by political historians. For charts showing when each of the two major parties was in and out of office, see the articles on Democratic Party and Republican Party.

Republican Party (1854-)
Democratic Party (1830?-)
National Republican Party (1825-1834)
Democratic-Republican Party (1792?-1825?)
Federalist Party (1787?-1816?)
Greenback Party (1874-1
Anti-Federalist Party (1787?-1792?)
Whig Party (1832-1860)

1788 1796 1804 1812 1820 1828 1836 1844 1852 1860 1868 1876

/hips—with the help of assistant whips—also try to as- ıre as much party discipline as possible by persuading ıembers to vote along party lines.

The majority party in each house has the most seats n House and Senate committees. In addition, the com- ıittee heads belong to the majority party. Congression- committees and subcommittees have great influence ı speeding or slowing the passage of legislation. They re often called "little legislatures." See **Congress of the** **nited States; House of Representatives; Senate.**

Providing opposition. In a democratic nation, the ırty or parties out of power have the duty of criticizing ıe policies of the party in power and offering alterna- ve programs. In France, Italy, and other countries that ave many parties, the opposition parties may represent ırious points of view—from those favoring a monarchy those preferring Communism. In most two-party na- ons, the party out of power usually provides unified pposition. But in the U.S. Congress, this is not always ue. Some members of the party that does not control e presidency may support the President's program gainst the wishes of their party leaders.

Raising funds for election campaigns is an important :tivity of political parties in democratic nations. Cam- ıigns are expensive, but parties must wage them to in elections. United States parties spend much more oney on election campaigns than do parties in other ıtions, partly because most U.S. campaigns last longer ıd employ television and other costly means of com- unication. It can cost millions of dollars to finance a ımpaign for a U.S. Senate seat in a large state, and any millions more to finance a presidential campaign. ıe cost of nominating and electing all U.S. public offi- als in a presidential-election year is over $1 billion.

Most campaign expenditures are for television and ra- o advertising, campaign consultants, polls, printing ıarges, telephone bills, campaign buttons, posters, and ılaries. Some campaign funds come from the small ontributions of thousands of party members and sup- orters. But most of the money comes from large dona- ons by wealthy people and institutional groups called *olitical action committees (PAC's).*

In the United States, several federal and state laws regulate campaign spending and contributions. But the laws have been difficult to enforce and have been generally ineffective in controlling expenditures because so many groups are involved in waging campaigns and raising funds. See **Election campaign; Hatch Political Activities Act.**

Other functions. In democracies, each party uses newspapers, radio, television, and other means to tell the people about its program. In so doing, a party hopes to win—or stay in—office. The party in power tries to justify its program. The minority party, on the other hand, points out what it considers weaknesses in the majority party's program and offers voters an alternative one. In publicizing their views, political parties thus help keep the voters informed on important issues.

Political parties also simplify complicated issues for the voters by reducing the issues to choices between candidates for office. In order to win votes, political candidates also look for problems that have not received public attention and that affect many people. In this way, political parties help force the government to act on neglected problems.

Party systems

The number of political parties that win a significant share of votes in major elections determines the kind of *party system* that a country has. A country may thus have a one-party, two-party, or multiparty system.

One-party systems are often associated with dictatorships. Most dictatorships allow only one party—the party that controls the government. Some dictatorships permit other parties, but only as long as they create no threat to the government.

In China, the Communist Party forms the government. No other party may exist. Party membership is considered a privilege and is granted only after a person meets certain standards. Only about 4 percent of the Chinese people belong to the party. The party performs many more functions than political parties in democracies. For this reason, it has elaborate organization for recruiting members and leaders, developing policy, indoctrinating the people, and maintaining discipline. See **Communism** (Communism in practice).

92 1900 1908 1916 1924 1932 1940 1948 1956 1964 1972 1980 1988 1996 2004

Most one-party dictatorships have elections. The elections are held chiefly to generate enthusiasm for the party. In China, for example, the candidates of the Communist Party tell the nation's people how wonderful Communism is. Party leaders explain what the party has done, what it plans to do, and what it expects of the people.

Two-party systems are most common in English-speaking nations. These two-party countries include the United Kingdom, with its Conservative and Labour parties; and the United States, with its Democratic and Republican parties. Although these nations also have other parties, one of the two major parties in each country usually controls the government.

Similar voting patterns also exist in most two-party countries. Generally, industrial areas of a nation support the more liberal party, and rural areas vote for the more conservative party.

Although a nation may have a two-party system, one party may control politics in certain areas of the country. The party has this control because most voters in such areas always vote for its candidates. In the United Kingdom, for example, certain *constituencies* (voting districts) always support the Conservative Party. Some of the country's other constituencies always support the Labour Party. In national elections, each party considers certain constituencies "safe." If party leaders want to be sure that a candidate will win a seat in Parliament, they have the candidate run in a safe constituency. In the United Kingdom, candidates for national office do not have to be a resident of the constituency they hope to represent.

In many states of the United States, both the Democratic Party and the Republican Party have considerable strength. In other states, one of those two parties has traditionally controlled politics. From the American Civil War (1861-1865) until the 1960's, for example, Democrats strongly controlled most of the Southern States. During that same period, the Republicans controlled—though less strongly—some of the New England and Midwestern states. Since the 1960's, however, the Republicans have won increasing support in the South and West, and the Democrats have made gains in New England and in the Midwest.

Large industrial and commercial cities in the United States, such as Chicago and New York City, generally vote for the Democratic Party. Rural areas, on the other hand, usually support candidates from the Republican Party.

Multiparty systems are found in many nations that have parliaments. Countries with multiparty systems include Belgium, Denmark, France, Italy, Japan, and Sri Lanka.

Most multiparty nations have four or five major parties. In addition, a nation may also have many minor parties. In most cases, each party seeks a particular economic or social goal. Multiparty systems vary from country to country. But most systems consist of one or two *left-wing* parties, which hold liberal or radical views; one or two *center* parties, which have moderate views; and one or two *right-wing* parties, which support conservative views.

In multiparty nations, one party rarely wins enough seats in the legislature to form a government. Consequently, two or more parties join forces and form a *coalition government* to direct the nation's affairs. But often, the coalition parties fail to agree on policies and programs, and so the government falls. The multiparty system thus tends to produce a less stable government than does the two-party system.

Party membership in the United States

Political parties in the United States have no strict requirements for membership. People are considered members of the party to which they consider themselves to belong. Therefore, neither the Republican Party nor the Democratic Party maintains accurate membership lists.

Some of the best evidence regarding party affiliation comes from voting surveys and public opinion polls. Such surveys and polls show that the majority of American voters who identify with a political party consider themselves Democrats. But party identification has never meant straight party voting. In the 1980 and 1984 presidential elections, for example, Republican Ronald Reagan received the votes of many people who normally thought of themselves as Democrats. These same people may have voted for Democratic candidates at the state and local levels. Such ticket-splitting is much more common in the United States than in other major countries.

Party organization in the United States

The Democratic and Republican parties are complicated organizations. Both parties are organized at the national, state, and local level. At each level, each party has three basic units. These units are the mass meeting, the committee, and specific leaders. The relationship between the three units varies at the three levels of government. It also varies from one state or community to another.

National conventions and committees. In theory, the national convention of each major political party has final authority in party matters. Actually, however, the convention has little power. Each party's national convention meets only once every four years, when it nominates the party's candidates for president and vice president. The national convention also goes through the formality of electing the national committee, which acts for the party between conventions. In reality, each state party chooses its representatives on the committee. To learn about the organization and activities of the national conventions and how the delegates to the conventions are chosen, see the *World Book* article on **Political convention**.

The national committee of both major parties consists of party representatives from the states, the District of Columbia, and the territories. The Republicans elect a committeeman and committeewoman from each area, and include each area's party chairperson. The Democrats have a much larger committee. Its representatives are apportioned by a complicated formula that is designed to include many special groups and to reflect party strength. Men and women must be equally represented on the committee.

Both the Democratic and Republican national committees have their headquarters in Washington, D.C. They meet only once, twice, or three times a year. One of the

ıain tasks of each committee is to organize its party's ext national convention. It chooses the city where the onvention will meet and makes arrangements for a moothly run convention. But most of the work of the arty's national organization is done by the committee's ational chairman and staff.

Each party's presidential candidate selects the na- onal chairman at the end of the national convention. he national committee then formally elects that person. he chairman acts for the national committee in manag- ıg party affairs. He or she may assist the President in *atronage* matters by recommending appointees for ederal jobs. During presidential elections, the chairman irects the party's fund-raising and other activities in the ational campaign.

The national chairman also organizes the party's na- onal headquarters and is the chief decision maker vithin the national organization. But the headquarters as a sizeable staff that does the detailed work. It has ampaign, fund-raising, public relations, and research ivisions.

State committees. Both the Democratic and Repub- can parties have a state committee in each state. In ıost states, the committee members are chosen in arty primaries or at conventions. The state committees rganize and manage campaigns for state offices and as- ist in local campaigns. They also raise money, make ar- angements for primary elections, and organize the state onventions.

The leader of the state committee is the official head f the state party. The committee formally elects the eader. But the governor, a U.S. senator from the state, r a group of powerful local officials actually hand-pick ıe leader. In most states, these officials are also power- ıl enough to lead the party and control the state com- ıittee. In some states, however, the committee leader ffectively directs the party and controls or even hooses key state party officers.

Local organizations. Each of the two major parties as a county committee in most counties of the United tates. Committee members are chosen by county con- entions or in primaries. The county committee elects ıe county leader, who maintains communication with ıe state party organization and, in most states, is a dele- ate to the state committee. Some county leaders retain atronage power, which they use to sway the votes of elegates at state and national conventions.

Below the county committees are the city, ward, and recinct organizations, whose leaders have the closest ontact with the voters. City and ward committeemen nd committeewomen are selected in local conventions r primaries. In some states, precinct committeemen nd committeewomen or captains are also chosen in rimaries. In others, the county committee selects them.

The United States has more than 146,300 election pre- incts. In most of them, either one or both major parties ave a precinct captain, committeeman, or committee- voman. This official prepares the party *poll book,* which sts the names of the voters in the precinct and which arty—if any—they belong to. Precinct captains and their ssistants try to make sure that all members of their arty are registered to vote.

In the past, precinct captains or committeemen and ommitteewomen frequently won votes by assisting voters and would-be voters. For example, they helped immigrants become citizens, bailed out prisoners under arrest, found jobs for unemployed persons, and sometimes gave out charity. But in many cities, local party leaders and bosses have lost the great influence they once had. Government welfare programs and rapid economic growth have made many voters less dependent on their help.

Development of parties in the United States

Early history. American leaders met in Philadelphia in 1787 to draw up the Constitution. This document makes no mention of political parties. In fact, George Washington, who presided over the Constitutional Convention, and many other early political leaders opposed their development. Nevertheless, common economic, political, and social interests brought people together to form political organizations. A group called the Federalists supported strong national government. Their opponents were called the Anti-Federalists. These political organizations began to take shape before Washington became President in 1789. Soon after, the two groups developed into the first American political parties, the Federalist Party and the Democratic-Republican Party. The Federalists, led by Alexander Hamilton, wanted a strong central government (see **Federalist Party**). The Democratic-Republicans, led by Thomas Jefferson, supported a weak central government (see **Democratic-Republican Party**).

After the 1816 presidential election, the Federalist Party broke up as a national organization, and the Democratic-Republican Party split into several groups. One of the Democratic-Republican groups came under the leadership of Andrew Jackson. By about 1830, Jackson and his followers were known as Democrats.

The Democratic Party is the oldest existing political party in the United States. Some historians believe it began in the 1790's as Jefferson's Democratic-Republican Party. Most historians trace its origin to the campaign organization that formed after the 1824 presidential election to win the presidency for Jackson in 1828.

From 1828 to 1860, the Democratic Party won all but two presidential elections—those of 1840 and 1848—even though its members often disagreed on several issues. They fought, for example, over banking policies, the slavery issue, and tariff rates. Democrats also met bitter opposition from outside the party. About 1832, several groups that opposed Jackson combined to form the Whig Party. But the Whigs never united sufficiently to propose a program with as much popular appeal as that of the Democrats. See **Whig Party**.

During the 1850's, the Democrats split over whether to oppose or support the extension of slavery. In 1860, the party even had two nominees for President—John C. Breckinridge and Stephen A. Douglas. Both lost to the Republican candidate, Abraham Lincoln.

From 1860 to 1932, only two Democrats won the presidency—Grover Cleveland in 1884 and 1892 and Woodrow Wilson in 1912 and 1916. The Republican Party had gained so much strength during the Civil War that the Democrats had great difficulty winning control of the government. In addition, the Republicans repeatedly charged the Democrats with having caused the war and having been disloyal to the Union.

The situation changed after 1929. Just as the Republicans had blamed the Democrats for the Civil War, so the Democrats blamed the Republicans for the stock market crash of 1929 and the Great Depression of the 1930's. The Democrats won the presidency in 1932 and continued to win every election from 1932 through 1948.

In the last half of the 1900's, however, neither the Democrats nor the Republicans dominated the presidential elections to any great extent. The Democrats won 5 out of the 12 elections during that period—in 1960, 1964, 1976, 1992, and 1996. But in the first election of the 2000's, the Democratic candidate lost. For more information, see **Democratic Party.**

The Republican Party started as a series of antislavery political meetings in the Midwest in 1854. At that time, the Whig Party was breaking up. Many Whigs—as well as Northern Democrats—opposed the extension of slavery. The Republican Party represented this viewpoint and thus gained followers rapidly. The party's first presidential candidate, John C. Frémont, ran in the 1856 election. He was not elected president, but he carried 11 Northern states.

From 1860, when Lincoln was elected, through 1928, when Herbert Hoover was elected, the Republican Party won 14 of the nation's 18 presidential elections. The policies of the Republican Party appealed to many groups, including farmers, industrialists, and merchants.

In 1912, President William Howard Taft was the leader of a divided Republican Party. Progressive Republicans wanted Theodore Roosevelt, who had been president from 1901 to 1909, to run again. But conservative Republicans renominated Taft at the party's 1912 national convention. Roosevelt then withdrew from the party and formed the Progressive, or "Bull Moose," Party. This split helped the Democratic candidate, Woodrow Wilson, win the election. The Republicans lost to Wilson again in 1916. They regained the presidency in 1920, and won in 1924 and 1928. But their popularity declined after the stock market crash of 1929.

During World War II (1939-1945), the Republicans began to show signs of recovery. In 1952, World War II military leader Dwight D. Eisenhower brought the Republicans their first presidential victory in 24 years. Eisenhower won reelection in 1956.

The Republicans lost to the Democrats in the 1960 and 1964 presidential elections but regained the presidency in 1968 and held it in 1972. They lost to the Democrats in 1976, but then were victorious in the next three elections—1980, 1984, and 1988. They were defeated in 1992 and 1996. In the first presidential election of the 2000's, the Republican candidate was the winner. For more information, see **Republican Party.**

Third parties. There have been many third parties in the United States. None of them ever won the presidency. But many of their proposals gained such widespread public support that the two major parties were forced to adopt them. These proposals included the convention system of nominating presidential candidates and the direct election of U.S. senators.

Third parties in the United States can be divided into five types, according to their origins and goals. The first type consists of groups that broke away from the two major parties. For example, the Liberal Republicans in 1872 and the Roosevelt Progressives in 1912 broke away from the Republican Party. Third parties that were formed by groups leaving the Democratic Party incluc the Gold Democrats, who left the party in 1896; the Di iecrats, who left in 1948; and the American Independe Party, which split from the Democratic Party in 1968.

The second type of third party consists of organizations formed chiefly to help a specific group of peopl For example, debt-ridden farmers established the Greenback Party in the 1870's and formed the Populist Party in the 1890's.

The third type is made up of left wing protest group They include the Socialist Party, which was founded ir 1901, and the American Communist Party, which was ganized in 1919.

The fourth type consists of parties that have only on goal. These single-issue parties include the nation's ol est existing third party—the Prohibition Party, which w founded in 1869. The Prohibition Party seeks to preven the manufacture and sale of alcoholic beverages in the United States.

The fifth type of third party consists of groups that have broad programs and attempt to gain national fav Examples of this type of third party include the Progre sive parties of 1924, 1948, and 1952; the Libertarian Par which was founded in 1971; and the Reform Party, esta lished in 1995.

Political parties in Canada

Canada has a combined parliamentary and federal system of government. Thus, the organization of its po litical parties resembles that of both the United Kingdc and the United States. Canada—like the United Kingdom—has a prime minister, who usually belongs to an is the leader of the majority party in the House of Com mons. But the political parties in Canada—like those in the United States—are both national and provincial (state) in their activities and organization.

Oldest parties. The two oldest parties in Canada ar the Conservative Party and the Liberal Party. Historicall they have also been the strongest parties. Both parties trace their origins to before 1867, when the British Nor America Act established the Dominion of Canada. In 1942, the Conservatives changed the name of their par to the Progressive Conservative Party. But most Canadi ans still call it the Conservative Party.

In 1867, John A. Macdonald, leader of the Conservative Party, became the first prime minister of Canada. H held office until 1873, when Alexander Mackenzie, hea of the Liberal Party, became prime minister. The Conse vatives regained control of the government in 1878 an held it until 1896. Between 1896 and 1935, one of the tw parties—or a Conservative-Liberal coalition—controlle the government. But since 1935, the Liberals have beer the dominant party in Canada.

Traditionally, the Liberals have favored the expansio of social programs and provincial rights. Conservatives have supported tighter controls on government spending.

Other parties in Canada have never won enough public support to control the federal government. The Liberals and the Conservatives have tried to make their programs broad enough to appeal to other parties.

The Progressive Party was the first Canadian party ot er than the Liberals and Conservatives to win more

t n 20 percent of the vote in a general election. In 1921, i;ained 64 seats in the House of Commons. But by 130, this farmer-supported party was no longer an ef-f tive organization.

n the 1930's, during the Great Depression, two oups of dissatisfied Canadians founded new parties— t: left-wing Co-operative Commonwealth Federation (:F) and the right-wing Social Credit Party. The CCF \'s formed in Alberta in 1932. It supported the estab-l ıment of a planned economy in Canada. The CCF con-t lled the government of Saskatchewan from 1944 to ;4. The party achieved its greatest national strength in 15, with 28 members in the House of Commons.

n 1961, the CCF joined with the Canadian Labour ıngress to form the New Democratic Party (NDP). The DP has considerable influence in British Columbia, lanitoba, Ontario, Saskatchewan, and the Yukon Terri-ty. It governed Saskatchewan during the early 1960's d from 1971 to 1982. It regained control there in 1991. e party held power in Manitoba from 1969 to 1977, m 1981 to 1988, and beginning again in 1999. It head- British Columbia's government from 1972 to 1975 d from 1991 to 2001. The NDP won control of the kon Territory's government in 1985 and controlled ıtario's from 1990 to 1995. The party made its largest ins at the national level in 1963, 1968, 1972, 1979, 1980, d 1988. After 1988, its strength in the House of Com-ıns declined.

The Social Credit Party, established in Alberta in 1935, pports the free enterprise system. This party con-lled the government of Alberta from 1935 to 1971. It verned British Columbia from 1952 to 1972 and from 75 to 1991. In 1962, the party won 30 seats in the use of Commons. But since then, its strength at the tional level has fallen sharply.

Another party, the Reform Party, was established in anitoba in 1987. By the early 1990's, it had gained ıch support across Canada—especially in the West.

In the 1990's, the Reform Party was one of two new rties that sharply increased their number of seats in House of Commons. The other party was the Bloc ıébécois. Founded in 1990 and based in Quebec, it pports sovereignty for Quebec. In the national elec-ns of 1993, the two new parties' gains nearly eliminat- the Conservatives from the House of Commons. The nservatives, however, later regained some of their t strength in the House.

In 2000, members of the Reform Party voted to dis-lve their party and join the newly created Canadian form Conservative Alliance. The new party, common-called the Canadian Alliance, favors such reforms as ducing the national debt and establishing a single-rate come tax. It strongly supports the free-enterprise sys-n. Charles O. Jones

Political prisoner is a person who is imprisoned, detained, or in certain other ways deprived of liberty because he or she opposes the government. There is little agreement on the precise legal definition of the term. For example, some organizations working to free political prisoners specify that such people are prisoners who are persecuted, more than prosecuted, by a government for their political beliefs. Other groups state

that a political prisoner is any person who is detained for posing a threat to government security. Amnesty International, a human-rights organization, seeks to release only those political prisoners who have not committed violent acts.

Treaties between nations protect political prisoners under certain circumstances. Some treaties exempt individuals from *extradition* (being sent to another country for trial) if they are charged with a political offense. Other pacts state that a country will grant political *asylum* (shelter and protection) to certain individuals who seek it. Nations also make agreements with one another to respect human rights within their own borders.

Besides Amnesty International, organizations working to free political prisoners include the International Committee of the Red Cross and the International Commission of Jurists. Surya Prakash Sinha

Political rights. See Citizenship.

Political science is the systematic study of political life. Political scientists seek answers to such questions as "What reasons justify the actions of government?" and "Whose interests are served by governments?" They study various forms of government as well as political parties, pressure groups, elections, international relations, and public administration. All these are activities of individuals and groups and involve basic human relationships. Political science deals with such fundamental values as equality, freedom, justice, and power.

Political science is closely related to economics, history, law, philosophy, and sociology. Economics deals with the control of all material resources, including goods and services, which affects the political power structure within a nation and among groups of nations. History provides much of the raw material with which the political scientist works. Law, especially public law, supplies a framework of formal ideas for the political scientist. Philosophy relates political science to the other sciences. Sociology provides understanding of the social developments that affect political life.

The study of political science has increased greatly with the growth and spread of democracy during modern times. In every democratic country, political science is essential in the processes of government. The political scientist studies these processes and the operations of government agencies and departments. The work of political scientists provides a factual basis for criticism and reform—probably the most important elements of democratic government. Many political scientists participate in government programs as advisers. They also act as consultants to legislators and other public officials. In addition, political scientists develop useful materials for the education of young people. Without that kind of training for future citizens, a democratic society could not prosper.

Fields of political science

In the United States, political science is generally divided into six main fields: (1) political theory and philosophy, (2) comparative government, (3) international relations, (4) American government and politics, (5) public administration, and (6) political behavior.

Political theory and philosophy are usually dealt with historically. Most political scientists believe that the history of political thought forms the basis of all political studies. They consider the reading of great books on political theory and philosophy to be essential for a broad education in politics. The writers of these works include Plato, Aristotle, Cicero, Saint Augustine, Saint Thomas Aquinas, Niccolò Machiavelli, Thomas Hobbes, Jean-Jacques Rousseau, John Locke, Montesquieu, Immanuel Kant, Georg Wilhelm Friedrich Hegel, and Karl Marx.

The classic political and philosophical works help political scientists explore and understand many issues of *empirical politics* (politics based on experience). With this understanding, political scientists can establish generalizations based on verified facts. These generalizations concern such subjects as how power is won or lost and the problems of representative government.

Comparative government. An understanding of political reality may be achieved by comparing the political institutions and practices of two or more countries. Some scholars in comparative government specialize by studying the countries of a particular area of the world.

International relations include diplomacy, international law, and international organization. Since 1945, much emphasis has been placed on the study of the United Nations. Vital forces in the modern world, including imperialism and nationalism, are also important subjects of international relations. In addition, this field of political science deals with defense policies and with problems connected with peace and war. The effects of economic pressures on international relations are studied as well.

American government and politics is a field of political science only in the United States. In Canada, the study of Canadian government and politics would take its place. Political scientists generally give special attention to their own country's government.

The U.S. government has a federal system. Study of the American government deals with national, state, and local government and politics.

American political scientists have made notable progress in arriving at realistic understandings of Congress, the presidency, and the Supreme Court. They have also studied federal government agencies, large corporations, interest groups, the mass media, and other centers of economic and social power. Political scientists have gained important insight into how these groups influence national decision making.

Public administration is actually part of comparative government and of American government and politics. It is separated from those fields because of the range and complications of modern administrative activities. Public administration deals with such tasks of public officials as accounting, budgets, and personnel management. Public officials often work closely with political scientists who are experts in administration. These experts study the departments of the federal, state, and local governments. They analyze how the organization and internal politics of these departments aid or hinder putting political decisions and programs into effect.

Political behavior is the field that explores the way people respond to certain political conditions or influences. For example, the political scientist may take note of how many voters favor a candidate who looks good on television. Behavioral studies are a recent trend in political science. They have been influenced by develop-

ments in such behavioral sciences as anthropology, psychology, and sociology. Political scientists have developed ways to study certain key behavior patterns in politics. Studies have been made in communications, propaganda, voting behavior, and other activities.

The development of political science

The ancient Greek philosopher Aristotle and his teacher, Plato, believed that the main task of political science was to work out a model political order. This political order would establish maximum justice and, at the same time, remain completely stable. Plato was primarily a philosopher of ideas. He derived his insight chiefly from *abstract speculation* (thinking about nonconcrete things). Aristotle, on the other hand, insisted on *empirical studies* (investigation based on experience) in constructing his political theories. See **Aristotle; Plato.**

Scholasticism was a major philosophical movement during the late Middle Ages. Its followers, often called *scholastics,* worked to fit the Greek tradition of political science into the religious framework of Christianity. Their main concern was to harmonize the power of government with ethics and moral laws.

The greatest scholastic was Saint Thomas Aquinas. He ranked all other political subjects below law. In one of his most important works, *Summa Theologica,* Aquinas elaborated Aristotle's theories and adapted them to Christian purposes. Aquinas emphasized certain rights and duties of individuals in the processes of government. He also stressed that government should rule in accordance with those rights and duties. By stating that government was limited by law, Aquinas helped lay the foundation of modern constitutionalism. See **Aquinas, Saint Thomas; Scholasticism.**

Secularism. The theories of the medieval philosophers were challenged in the 1500's and early 1600's. Niccolò Machiavelli, a famous Florentine politician, pushed aside Christian idealism in favor of realistic power politics. Machiavelli's ideas were generalized by Thomas Hobbes, an English philosopher. In Hobbes's view, a person's entire life is a "ceaseless search for power." This approach became known as *secularism* because it separated politics from religion. Three writers who put those ideas into legalistic form were Jean Bodin, a French jurist; Johannes Althusius, a German political scientist; and Hugo Grotius, a Dutch lawyer who founded the science of international law.

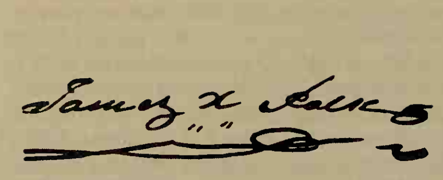
Constitutionalism is a political system in which the powers of government are in fact limited by law or tradition. Constitutionalism developed during the mid-1600's as a reaction to *absolutism*—that is, absolute rule by one person. The reaction was especially strong in England, where it was climaxed by the Glorious Revolution of 1688 (see **England** [The Restoration]).

Several English writers influenced the basic theories of Western constitutionalism, including Richard Hooker, John Milton, and James Harrington. John Locke, perhaps the most influential political writer of the time, emphasized basic human rights and believed that people should revolt against governments that violated those rights. His book *Two Treatises of Government* (1690) greatly influenced political thought in the American colonies. Locke's ideas helped shape the Declaration of Independence and the U.S. Constitution.

Liberalism developed as a political philosophy largely from the theories of Locke. Liberalism represents a willingness to change ideas, proposals, and policies to meet current problems. Locke's theories were given a broader base by Montesquieu, one of a group of French writers called the *philosophes.* Liberal theories were reinforced by the radical *individualism* of Jean-Jacques Rousseau and the *utilitarian* theories of David Hume, a Scotsman, and Jeremy Bentham, an Englishman. Individualists believe that freedom of the individual is as important as the welfare of any community. Utilitarians believe that the goal of politics is "the greatest happiness of the greatest number." John Stuart Mill, an English philosopher and economist, summarized most of the liberal ideas that had developed up to his time.

Three great German philosophers contributed liberal ideas that were somewhat different from classic liberalism. They were Immanuel Kant, Johann Gottlieb Fichte, and Georg Wilhelm Friedrich Hegel. The liberalism of Fichte and Hegel included ideas of socialism and nationalism. Kant's liberalism included a theory of universal peace through world organization. Kant explained his theory in *On Eternal Peace* (1795). See **Liberalism.**

Democracy and socialism. Some of Rousseau's writings carried his political theories beyond radical individualism. In *The Social Contract* (1762), Rousseau became the theorist of democracy. His emphasis on the *collective*—the general will, as Rousseau described it—gave rise to socialism. Eventually, the theories about democracy became divided. Liberal, constitutional, democratic ideas were followed in the United States. Socialist democratic ideas became predominant in Europe.



Socialism was further developed by Karl Marx, a German philosopher and economist. He first expressed his socialist ideas in the *Communist Manifesto* (1848), which he wrote with his colleague Friedrich Engels. Communism in the Soviet Union was based on Marxist doctrines as interpreted and modified by V. I. Lenin, who led the Russian Revolution in 1917. Marxism-Leninism differs greatly from the Marxist doctrines followed by democratic socialists in many countries of Western Europe. See **Communism; Democracy; Socialism.**

Contemporary ideas. Since about 1900, most political scientists have sought increasingly to strengthen the empirical basis of their work. They have been returning to Aristotle's view of basing political theories and methods on experience. As a result, much progress has been made in descriptive and analytical work, and in *quantitative studies* (studies that collect data in numerical form), such as opinion polls. Today, political scientists make practical improvement and political reform their major concerns. Many current political studies consider most nations of the world. Such global interests find expression in the International Political Science Association. About 40 national political science associations work together in this organization. Robert L. Cord

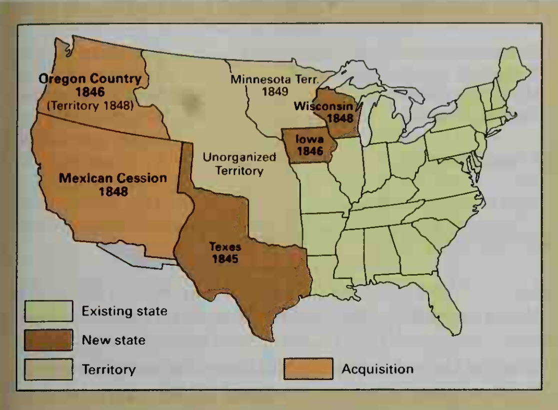
Vice president
1845-1849

Polk, James Knox (1795-1849), was president when the United States added the greatest amount of new territory to the country. During his presidency, the American flag was raised over most of the area now forming nine Western States, and Texas became a member of the Union. Polk successfully directed the Mexican War, which won much of this territory. He carried out every item of his political program. Of all other American presidents, only George Washington had such a clear record of success.

Polk's era was the "Fabulous 40's." The country seethed with excitement, energy, and prosperity. Covered wagons were crowding the Oregon Trail, heading west across the prairies and mountains to the Pacific Coast. The telegraph, a new wonder, carried news of Polk's nomination. The discovery of gold in California started one of the greatest movements of people in American history. On their way west, the "Forty-Niners" sang such songs as "Be Kind to the Loved Ones at Home" and Stephen Foster's "Oh! Susanna." Such writers as Ralph Waldo Emerson, Henry David Thoreau, Nathaniel Hawthorne, Henry Wadsworth Longfellow, James Russell Lowell, John Greenleaf Whittier, and Edgar Allan Poe produced the "Golden Age of American letters."

The national scene had its unpleasant side, too. Reformers called attention to the hardships of children working in factories and to the poverty of immigrants. Slavery rested uneasily in the thoughts of many Americans. A lack of concern by Polk for these social problems made reformers dislike him. They regarded him as a tool of the slaveowners. Their unfriendly writings outlived Polk's reputation for success. This explains why, for a time, history held Polk in low regard.

Although Polk was a close friend and follower of the great statesman Andrew Jackson, he lacked Jackson's personal attraction. Polk was a cold, silent, narrow, and ungenerous person. He did not seek a second term, and few people regretted it.



The nomination of Polk by the Democratic Party in 1844 surprised the nation. But Polk defeated the Whig candidate, the famous Henry Clay, because he understood the desire of Americans to see the United States become more powerful. Like most Americans of his day, Polk believed it was the "manifest destiny" of the United States to expand across North America. In this sense, he appears to deserve the tribute of George Bancroft, the great historian who served as his secretary of the Navy. Bancroft called Polk "prudent, farsighted ... one of the very foremost of our public men, and one of the very best and most honest and most successful presidents the country ever had."

Early life

Childhood. James Knox Polk, the son of Samuel Polk and Jane Knox Polk, was born on Nov. 2, 1795, on a farm near Pineville, North Carolina. The Polks had emigrated from Ireland to America. The family name was originally *Pollock* or *Pollok*. In time it became *Polk,* after being repeatedly mispronounced *Poll'k*.

In 1806, Samuel Polk moved his large family to the fertile Duck River Valley in central Tennessee. He combined farming and surveying with land speculation and became one of the wealthiest men of his region.

James, the oldest of 10 children, was a small and sickly boy. His parents spared him many of the chores done by most farm boys. But James learned to help his father survey and manage the large farms. He later worked briefly as a clerk in a general store.

Western acquisitions during Polk's presidency extended the U.S. border to the Pacific Ocean. Three states—Texas, Iowa, and Wisconsin—joined the Union during the period.

The U.S. flag had 30 stars when Polk left office. Stars were added for Florida, which became a state just before he took office, and for Texas, Iowa, and Wisconsin.

The world of President Polk

"Manifest destiny" was a phrase used to justify the territorial expansion of the United States during the 1840's. The phrase expressed the belief that the United States should rule all of North America because of the nation's growing population and its economic and political superiority.
Edgar Allan Poe won popularity with his volume of poetry, *The Raven and Other Poems,* published in 1845.
Clipper ships were launched for the first time during the mid-1840's. Many of these swift, graceful vessels sailed from the east coast of the United States, around the tip of South America, and on to China to pick up loads of tea.
A potato famine in Ireland caused about 1 $\frac{1}{4}$ million Irish to immigrate to the United States in the mid-1800's.
American composer Stephen Foster wrote many songs for minstrel shows, which first became popular in the 1840's. His best-known tunes included "Oh! Susanna" and "Swanee River."
Mormons led by Brigham Young founded the State of Deseret (now Utah) in the Great Salt Lake valley in 1847.
Liberia became the first black republic in Africa in 1847.
The discovery of gold in California in 1848 triggered the nation's first great gold rush.
The Communist Manifesto was issued by Karl Marx and Friedrich Engels in 1848.
The first Woman's Rights Convention was held in Seneca Falls, New York, in 1848 under the leadership of Lucretia Mott and Elizabeth Cady Stanton. Delegates discussed women's rights in such areas as divorce, property control, and voting.

WORLD BOOK map

Education. Polk studied for a year in the Zion Church in Maury, then entered the Murfreesboro Academy. In 1815, he entered the sophomore class of the University of North Carolina. He graduated at the top of his class in 1818.

After graduation, Polk returned home and entered the law office of Felix Grundy, one of the foremost lawyers and politicians in Tennessee. Grundy introduced him to Andrew Jackson. After a year of study, Polk was admitted to the bar in 1820. He began to practice in Columbia and soon had all the cases he could handle.

Political and public activities

Lawyer and legislator. Politics proved more attractive than law. Polk's short height and his speeches on behalf of the Democratic Party won him the nickname of "Napoleon of the Stump." In 1821, while still practicing law, he became chief clerk of the Tennessee Senate. He was elected to the Tennessee House of Representatives in 1823. There he worked to improve the state school system and to reduce taxes. More important to his future, he decided to support Andrew Jackson's presidential ambitions. "Old Hickory" took a keen interest in Polk's political career. The two men became so close that Polk received the nickname of "Young Hickory."

Polk's family. In nearby Murfreesboro, Polk met and courted Sarah Childress (Sept. 4, 1803-Aug. 14, 1891). She was the daughter of a well-to-do country merchant. She had been brought up in a strict religious environment and attended the Salem Female Academy, founded by the Moravian Church. She and Polk married in a large country wedding on New Year's Day in 1824. Mrs. Polk encouraged her husband's political career, and she proved to be his closest political adviser throughout his career. Mrs. Polk was devoted to Jackson, whom she called "Uncle Andrew." In turn, Jackson called her "Sally." The Polks had no children.

Congressman. In 1825, Polk was elected to the first of seven consecutive terms in the United States House of Representatives. He was one of its youngest members and quickly established himself as a loyal Democratic Party man. He attracted attention by his bitter opposition to the policies of President John Quincy Adams, who had defeated Jackson in 1824.

In 1835, during Jackson's presidency, Polk became speaker of the House. He worked hard, and in 14 years as a congressman was absent only once. During his three years as speaker, Polk claimed that he had "to decide more questions of parliamentary law and order" than all his predecessors combined.

Governor. In 1839, Jackson persuaded Polk to run for governor of Tennessee. Jackson felt that only Polk could unite the state Democratic Party, which had been torn by internal strife and by Whig victories of the previous four years. Polk won the election. In his inaugural address, he announced that he supported states' rights and slavery and opposed the centralization of powers in Washington.

Important dates in Polk's life

1795	(Nov. 2) Born near Pineville, North Carolina.
1806	Moved to Tennessee.
1824	(Jan. 1) Married Sarah Childress.
1825	Elected to the U.S. House of Representatives.
1835	Elected speaker of the House.
1839	Elected governor of Tennessee.
1844	Elected president of the United States.
1849	(June 15) Died in Nashville, Tennessee.

Detail of an oil portrait; James K. Polk Memorial Association

Sarah Childress Polk was a deeply religious, well-educated woman. She assisted her husband throughout his career and became his closest political adviser.

Polk shunned the social life of the state capital. He complained that he "could not lose half a day just to go and dine." He lost his bid for reelection in the Whig landslide of 1841. He ran again in 1843, but lost.

Meanwhile, Polk's interests had shifted back to the national scene. He felt he had Jackson's support for the vice presidency. He probably toyed with the idea of the presidency, but neither he nor anyone else took his chances for that office seriously in 1843.

Election of 1844. A combination of circumstances now played into Polk's hand. Former President Martin Van Buren was again the leading candidate for the Democratic nomination. The annexation of Texas was the chief political issue of the day. Van Buren opposed immediate annexation because it might lead to war with Mexico. This position cost Van Buren the support of the West and of the South, which sought to expand slave territory. Polk cleverly argued that Texas and Oregon had always belonged to the United States by right. He called for "the immediate reannexation of Texas" and for the "reoccupation" of the disputed Oregon Territory.

At the Democratic presidential convention of 1844, Van Buren failed to win the two-thirds vote then required for nomination. The delegates could not agree on Van Buren or his chief rival, Lewis Cass of Michigan, a former U.S. minister to France. On the eighth ballot, the historian George Bancroft, a delegate from Massachusetts, proposed Polk as a compromise candidate. On the next roll call, the convention unanimously accepted Polk, who became the first "dark horse," or little-known, presidential candidate. The delegates selected Senator Silas Wright of New York for vice president. But Wright, an admirer of Van Buren, rejected the nomination. This was the first time a man actually nominated for vice president refused to run. The Democrats then nominated George M. Dallas, a Pennsylvania lawyer.

Polk was not well known nationally, and many people

asked, "Who is James K. Polk?" This question became a Whig campaign slogan. The Democrats countered with their slogan of "Fifty-Four Forty or Fight!" They meant that the United States should have the entire Oregon Territory, north to the latitude of 54° 40', even if the country had to go to war with the United Kingdom for it.

The Whigs nominated former Senator Henry Clay of Kentucky for president and chose Senator Theodore Frelinghuysen of New Jersey for vice president. Polk, a relative unknown, was opposing a man who twice had run for the presidency and lost. Clay tried to keep the Texas issue out of the campaign because he feared he would lose the Northern antislavery vote if he supported annexation. Polk took a forthright position for annexation. He won the election by about 40,000 votes.

Polk's administration (1845-1849)

A cold, steady rain swept the unpaved streets of Washington during Polk's inauguration. The new president confided to Bancroft, whom he had appointed secretary of the Navy, that "there are four great measures which are to be measures of my Administration." Polk's four goals were to: (1) reduce the tariff, (2) reestablish an independent treasury, (3) settle the Oregon boundary dispute with the United Kingdom, and (4) acquire California. He was to achieve all these objectives.

Life in the White House changed greatly during Polk's administration. The Polks held informal evening receptions twice a month in the Executive Mansion, where gaslights for the first time replaced oil lamps and candles.

As first lady, Mrs. Polk continued to take an active interest in political affairs. A keen editor, she looked over and approved her husband's writings. She read newspapers and clipped items for her husband to see.

Because of Mrs. Polk's strict religious beliefs, she and the president refused to attend the theater or the horse races. Mrs. Polk banned dancing, card-playing, and alcoholic drinks from the White House. She also refused to permit visitors in the White House on the Sabbath. Polk even declined to accept the credentials of the Austrian minister who called on him at the White House on a Sunday. The Polks attended the First Presbyterian Church regularly, although Polk himself joined no church until shortly before he died.

Tariff reduction. Polk had long favored a tariff for revenue only, with "protection being incident and not the object." Robert J. Walker, Polk's secretary of the treasury, drafted a tariff law, and Congress passed it in 1846. The Walker Tariff included some protective features. But it admitted tea and coffee duty-free and also generally lowered rates. This law was the first tariff to be drafted by the executive branch of the government and

the first to be based on the value, rather than on the quantity, of imports.

An independent treasury. Less than a week after passing the tariff bill, Congress set up an independent treasury to hold and disburse federal funds. Subtreasuries were established in several major cities. President Van Buren had persuaded Congress to create such federal depositories, independent of private business and state banks. But the Whigs had repealed the law in 1841. The Independent Treasury Act of 1846 formed the basis of the nation's fiscal system until Congress passed a law that established the Federal Reserve System in 1913 (see **Federal Reserve System**).

"Oregon fever" swept the country in the early 1840's. Beginning in 1843, thousands of pioneers journeyed along the Oregon Trail and settled along the banks of the Willamette and Columbia rivers in the Oregon Territory. The British, who were strongly established north of the Columbia, claimed the entire territory. The dispute between the United States and the United Kingdom had been "settled" in 1818 by an agreement for joint occupation. Now many members of Congress demanded an end to that agreement. They clamored for American possession of the territory, all the way north to the latitude of 54° 40'.

During the 1844 presidential campaign, Polk maintained that title to the Oregon Territory was "clear and unquestionable" because of American settlements there. As president, he modified his position. He did not want to fight the United Kingdom over the disputed territory, particularly because war with Mexico appeared near. But he confided in his diary that "the only way to treat John Bull is to look him straight in the eye." First, Polk renewed an earlier offer to compromise on the 49th parallel. The United Kingdom rejected the offer, but later made the same proposal, which became the basis of the Oregon Treaty of 1846. See **Oregon Territory**.

New York Public Library

The Mexican War achieved Polk's goal of acquiring California for the United States. This picture shows the victorious entrance into Mexico City of American General Winfield Scott.

The Mexican War achieved the fourth of Polk's goals, the acquisition of California. Earlier he had offered to buy California from Mexico. But Mexico had no intention of selling, particularly because it was then engaged in a dispute with the United States over Texas, a former Mexican possession.

The United States had annexed Texas, but Mexico refused to give up its claims or agree to a boundary for the new state. Polk then ordered American troops to occupy disputed territory south of the Nueces River. American General Zachary Taylor advanced to the bank of the Rio Grande. On April 25, 1846, Mexican troops crossed the river near Matamoros and battled American cavalry. Many historians believe that Mexico had a valid claim to the land where the battle took place. But on May 11, Polk asked Congress to declare war, saying that "Mexico has passed the boundary of the United States, has invaded our territory, and shed American blood on American soil."

The Mexican War ended in an American victory. Under the peace treaty signed in 1848, Mexico gave up all claims to Texas and also ceded land forming all or part of present-day Arizona, California, Colorado, Nevada, New Mexico, Utah, and Wyoming. The United States paid Mexico $15 million for the land and also took responsibility for paying $3 million in damage claims made by American citizens against Mexico.

"The Polk Doctrine." A few months after the Mexican War, Polk reaffirmed and extended the Monroe Doctrine in a special message to Congress (see **Monroe Doctrine**). The president said that the doctrine was "our settled policy, that no further European colony or dominion shall, with our consent, be planted or established on any part of the North American Continent." Polk extended the doctrine to cover European interference in the relations among American countries.

Retirement. When Polk had accepted the nomination for president in 1844, he declared he would "enter upon the discharge of the high and solemn duties of the office with the settled purpose of not being a candidate for reelection." He was the first president not to seek reelection. Polk left the nation not only his record of political accomplishment and territory acquired, but also a diary that is an invaluable record of his presidency.

After his successor, Zachary Taylor, was inaugurated, the white-haired Polk returned to his home in Nashville, Tennessee, worn out by four years of hard work. He became ill with cholera and died on June 15, 1849. Polk was buried in the city cemetery and later reburied on the grounds of his estate, "Polk Place." Mrs. Polk lived at Polk Place until her death in 1891 and was buried beside her husband. In 1893, the Polks' remains were moved to a tomb on the grounds of the Tennessee Capitol in Nashville. Sam W. Polk, *pohk,* **Leonidas,** *lee AHN ih duhs* (1806-1864), an Episcopal bishop, was a Confederate general in the American Civil War. He commanded the defense of the Mississippi River in 1861. Polk fought in the battles at Belmont, Missouri; Shiloh, Tennessee; Perryville, Kentucky; and Murfreesboro, Tennessee. He led a corps at Chickamauga, Georgia, and served in the Atlanta campaign. Polk was killed in action at Pine Mountain, Georgia.

Polk was born on April 10, 1806, in Raleigh, North Carolina. He graduated from the United States Military Academy. In 1827, he left the army to study for the ministry. In 1841, he became the first Protestant Episcopal bishop of Louisiana. Polk helped found the University of the South in Sewanee, Tennessee. Steven E. Woodworth

Poll. See **Election; Public opinion poll.**

Poll tax is a tax levied equally on all the citizens of a community. The amount of the tax is the same for a poor person as it is for a rich one. The term *poll tax* comes from the old English word *poll,* which means *head.* Many people refer to it as a *head tax.* A poll tax is sometimes called a *capitation* tax, from the Latin word *caput,* meaning *head.* Some people object to poll taxes because they feel taxes should be based only on income and property. However, many economists favor poll taxes because they believe that such taxes do not lessen a person's incentive to earn more money.

The United States has never levied a national poll tax. But in the past, laws in several states required that a citizen who did not pay the poll tax could not vote. Amendment 24 to the United States Constitution, ratified in 1964, made it illegal for a state to use payment of taxes as a voting requirement in national elections. In 1966, the Supreme Court of the United States declared poll taxes unconstitutional if they are used as a requirement for voting in state and local elections. The court held that such taxes violated the equal protection of the law guaranteed by Amendment 14 to the United States Constitution. Vito Tanzi

Pollaiuolo, *POH ly WOH loh,* **Antonio del** (about 1432-1498), was an Italian sculptor and painter. The ways in which he portrayed the human body in his sculpture and painting greatly influenced the work of the Renaissance artists Andrea del Verrocchio, Leonardo da Vinci, and Michelangelo.

Pollaiuolo was born in Florence. About 1460, he completed three large paintings of the deeds of Hercules. These paintings have not survived, but two small versions show figures struggling furiously. He reworked the subject of *Hercules and Antaeus* in a small bronze group that is so powerful in its expressive use of anatomy that viewers feel they are participating in the action. Pollaiuolo lived in Rome from about 1483 until his death, designing and casting the bronze tombs of Popes Sixtus IV and Innocent VIII. Roger Ward

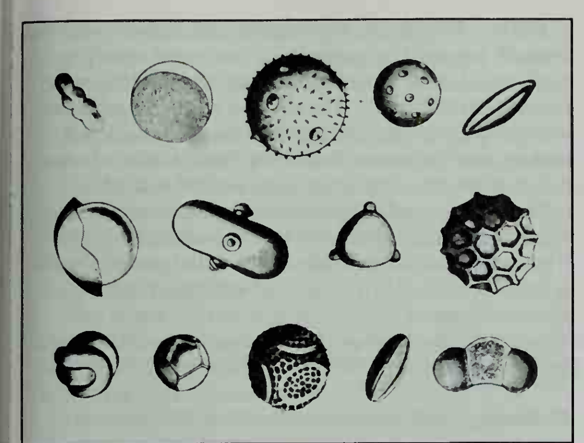
Pollen consists of tiny grains that are produced in the male organs of flowering and cone-bearing plants. Seeds develop after pollen is transferred from the male part of a plant to the female part. This transfer of pollen is called pollination.

Most pollination is carried out by birds, insects, and the wind. Most flowers pollinated by birds and insects have colorful blossoms and an odor that attracts the animals. When birds and insects come into contact with a flower, pollen clings to their bodies, and they then carry the grains to other flowers. The wind blows pollen from one flower or cone to another. Most flowers pollinated by the wind have neither bright colors nor a fragrant odor.



A flowering plant produces pollen in its *stamens,* the male parts of a flower. After pollination, seed development occurs in the female part, called the *pistil.* A cone-bearing plant produces pollen in its *male pollen cones.* Pollination occurs when the wind carries pollen from the male pollen cones to the *female seed cones.*

Many people are allergic to pollen. Large amounts of pollen in the air cause them to develop hay fever. This allergy results in headaches, red and itching eyes, a runny nose, and sneezing. Ragweed pollen is the most common cause of hay fever in the United States.

Fossilized pollen grains are often preserved in sediments from lakes and bogs. By studying these grains, scientists can learn much about the plant life and climate of earlier ages.

Pollen grains

Pollen grains vary in shape, size, and surface features. These variations make the grains of each species of

Brooklyn Botanic Garden

Pollen grains are so small that they look like tiny specks to the unaided eye. But they have definite shapes and surface patterns depending on the kind of plant that produced them.

plant different. Most pollen grains are round or oblong and range from 15 micrometers to more than 200 micrometers wide. (About 25,000 micrometers equal 1 inch.) Every pollen grain has an outer shell, which may be smooth or wrinkled, or covered with spines or knobs. This shell prevents the inner cells from becoming dry.

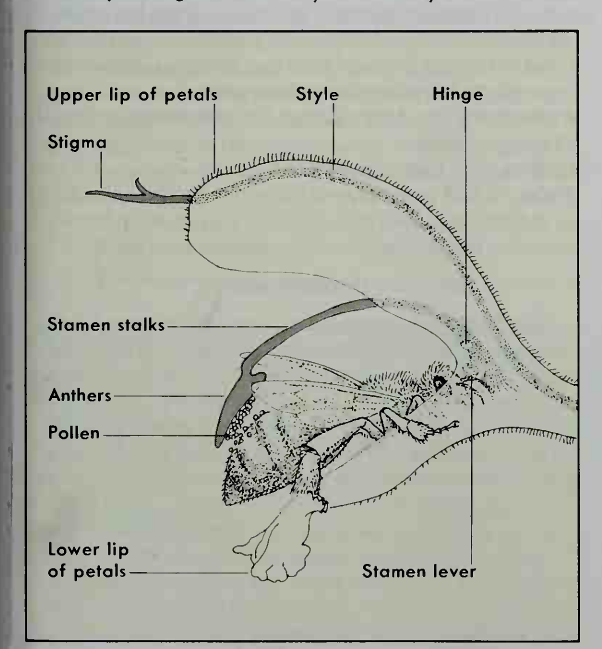
Such plants as corn, wheat, and pine trees, which are pollinated by wind, produce huge amounts of pollen. A corn plant can produce more than 18 million grains. But some plants that are pollinated by birds and insects produce only a few thousand grains.

Most pollen grains live only several days or weeks after being released. However, the cells of date palm pollen live for as long as a year.

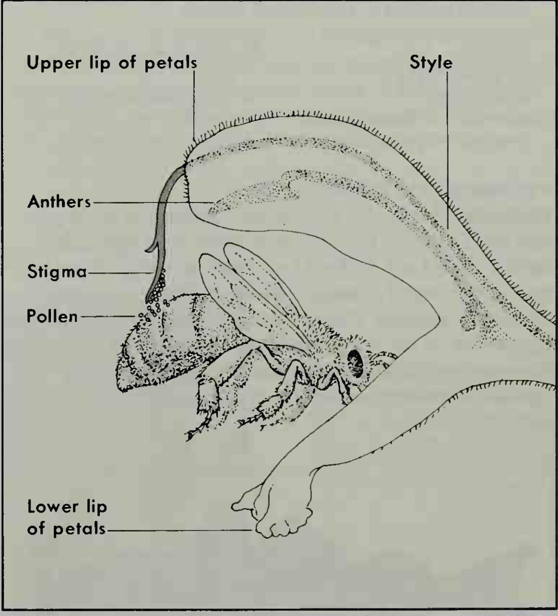
Methods of pollination

There are two methods of pollination, *cross-pollination* and *self-pollination.* Cross-pollination is the transfer of pollen from the stamens of one flower to the pistil of a flower of another plant. Self-pollination occurs when pollen is transferred from the stamens of one flower to the pistil of the same flower, or to another flower on the same plant.

Cross-pollination is the most common method. For seeds to develop, cross-pollination must occur between flowers of the same or closely related species.



Honey bees carry out more cross-pollination than any other kind of insect. They make honey from nectar and use pollen for food. Honey bees collect pollen in small cavities on their hind legs and carry it back to the hive. However, some pollen clings to their bodies and is carried to other flowers. Other insects that carry pollen include ants, beetles, butterflies, and moths.



Among birds, hummingbirds are the most important pollinators. They insert their long, thin beak into flowers and drink the nectar. Pollen sticks to the beak and is carried to the pistils of other flowers.

The wind pollinates many plants, including birches, corn, grasses, cattails, oaks, and ragweeds. It may carry pollen grains 100 miles (160 kilometers) or farther.

Botanists have used artificial cross-pollination to create new varieties of corn, cotton, wheat, and other plants. They use special brushes to transfer pollen from one plant to another.

Self-pollination. Many plants, including beans, cotton, oats, peas, and wheat, normally pollinate them-

WORLD BOOK diagrams by Marion Pahl

Pollination of the European sage is a complicated operation. When a bee enters a young flower, *left,* the insect's head hits the stamen lever. This hinged lever causes the anthers to swing downward, depositing pollen on the bee's back. If the bee goes later to an older flower, *right,* pollination will occur. In the older flower, the stigma droops down to receive pollen. As the bee enters the flower, the pollen is brushed off its back and sticks to the stigma.

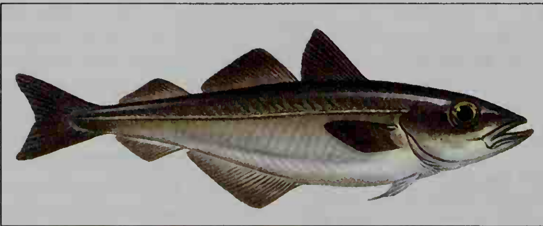
selves. Certain cross-pollinating plants, such as pansies and some violets, can also self-pollinate.

The growth process and the structure of some flowers prevent self-pollination. In plants called crane's-bills and spiderworts, for example, the stamens ripen earlier than the pistils. Therefore, the pollen is shed from the stamens before the pistils of the same plant become ripe. Willow trees and other species have *imperfect flowers*. In such species, each plant bears flowers with either stamens or pistils, but not both.

Fertilization

All flowering and cone-bearing plants produce seeds through *fertilization*. In fertilization, which occurs after pollination, a male sperm cell unites with a female egg cell.

In flowering plants, the egg cells develop in the *ovary*, the base of the pistil. The sperm cells are produced by the pollen grains. After pollination, a pollen grain swells as it absorbs water, sugar, and other materials from the *stigma*, the top of the pistil. The pollen then *germinates*—that is, it grows a tube downward to the *ovary*, where one or more *ovules* are located. The ovules are the structures that contain the egg cells. After the pollen tube reaches an ovule, it releases two sperm. One sperm fertilizes an egg cell. The second sperm fertilizes two female structures called the *polar nuclei*. The union of the second sperm with the polar nuclei produces the *endosperm*, the food-storage tissue of the new seed. Only flowering plants form seeds through such *double fertilization*.



In cone-bearing plants, the sperm and egg cells develop in the male cones and female cones. After pollination, one of the two sperm fertilizes an egg. The other sperm disintegrates. Richard C. Keating

Pollock, *PAHL uhk,* also spelled *pollack,* is an important food fish that belongs to the family of fish called codfish (see **Cod**). Pollocks account for a significant portion of the world's annual fish catch. There are three species of pollock. The *walleye pollock,* also called *Alaska pollock,* is the most important commercial species. It lives in the northern Pacific Ocean. The other two species of pollock are found in the northern Atlantic Ocean.

WORLD BOOK illustration by Colin Newman, Bernard Thornton Artists

Pollock is a popular food fish.

Pollock differ from other codfish since their lower jaw extends beyond the upper jaw. The Atlantic species grow to 3 ½ feet (1 meter) long and can weigh up to 66 pounds (30 kilograms). The walleye pollock is smaller, weighing up to 11 pounds (5 kilograms). Pollock live mainly near the ocean floor. They feed chiefly on small fish and they also eat other small aquatic animals.

The walleye pollock is sold fresh or frozen. It is also *filleted* (deboned) and made into fish sticks. In addition, it is used to prepare a fish mixture called *surimi,* which is used in making fish cakes and artificial crab meat.

Vidar G. Wespestad

Scientific classification. Pollock are members of the codfish family, Gadidae. The scientific name for the walleye pollock is *Theragra chalcogramma.*

Pollock, *PAHL uhk,* **Jackson** (1912-1956), was an American artist who had an important influence on modern painting as an important figure in the abstract expressionist movement. He devised a painting technique in which he dripped paint onto his huge canvases. The drippings formed sweeping, rhythmic patterns of line that seem to weave across the surface.

Pollock painted with his canvas on the floor. He said, "I feel nearer, more a part of the painting, since this way I can walk around it, work from the four sides, and literally be *in* the painting." The attitude that the working artist is *in* the painting is generally considered characteristic of abstract expressionism.

Pollock was born in Cody, Wyoming. From 1929 to 1931, he studied with Thomas Hart Benton at the Art Students League in New York City. He worked in the Federal Art Project from 1938 to 1942. Pollock painted in an expressionistic symbolic style before moving to pure abstraction in the late 1940's. In his last works, he returned to certain figurative references from his earlier works. He combined them with the loose forms developed in his technique of pouring, dripping, and working with sticks rather than with brushes. Dore Ashton

Pollution. See **Air pollution; Environmental pollution; Water pollution.**

Pollux. See **Castor and Pollux.**

Polo is a ball game played on horseback on an outdoor or indoor field. Two teams of four players each try to drive the ball through their opponents' goal posts.

Outdoor polo

The field and equipment. A regulation polo field is 300 yards (274 meters) long and 200 yards (183 meters) wide. The field is only 160 yards (146 meters) wide if the sidelines are boarded. The sideboards are 11 inches (28 centimeters) high. The goal posts are made of light material so that they will break easily if a horse runs into them. The posts are spaced 24 feet (7.3 meters) apart at opposite ends of the field.

Polo players use plastic or wooden balls that are 3 to 3 ½ inches (7.6 to 8.9 centimeters) in diameter. The balls weigh 3 ½ to 4 ½ ounces (99 to 128 grams). The players carry cane or rattan mallets from 48 to 54 inches (122 to 137 centimeters) long. At one end of the mallet is a horizontal piece of hardwood, and at the other end, a lightweight strap made of *web* (a strong cloth material). The strap fastens to the thumb. A player's equipment usually consists of boots, white breeches, knee guards, whip, spurs, mallet, helmet, and a jersey.

The horses. Polo horses, or *polo ponies,* are not of any special breed or size. Thoroughbreds and three-quarter thoroughbreds are generally considered the most acceptable.

It takes six months to a year to train a polo pony. It must be able to stop quickly, and to turn, twist, and resume stride with little loss of speed. Most difficult of all, the horse must have the courage to bump into another horse upon the command of its rider. The horse's equipment consists of saddle, bridle, bit, and leg boots or bandages.

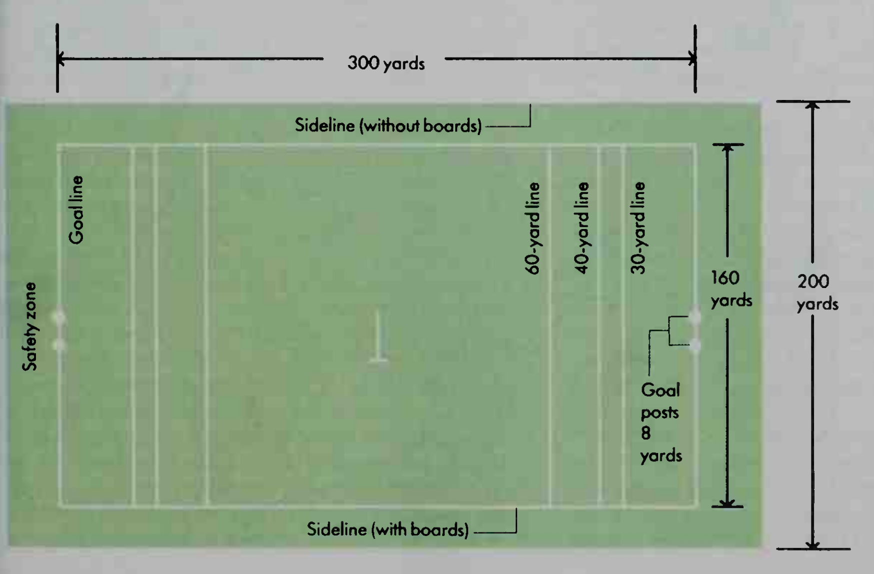
The game. At the start, each team is stationed in the center of the field to defend its respective goal. The first two riders play *forward* (offensively) while the third and fourth play *back* (defensively).

Tournament rules dictate whether there are four or six *chukkers* (periods). Each chukker is 7 minutes long. Four-minute intervals are allowed between chukkers for the players to change horses. The half-time intermission is ten minutes.

Games are played on the *handicap basis,* except for the U.S. Open tournament. Polo players have handicaps ranging from −2 to 10. The best players have the highest handicaps. The handicaps of each team's members are added to make sure the team's total handicap does not exceed the limit set for the tournament. If it does exceed the limit, the team cannot play in the tournament. On the handicap basis, the total team handicaps may count in the scoring. For example, if team *A* has a handicap of 20 and team *B* of 17, the game starts with a score of 3-0 in favor of team *B*.

Leo de Wys

A polo match is a contest between two teams of expert horsemen. Each team attempts to score goals by hitting a ball through its opponent's goal posts with long-handled mallets.



Other kinds of polo

Arena polo is played on indoor fields of sand, clay, or dirt. Each team has three players. The rules are similar for both outdoor and arena polo except for the size of the field, the type of ball used, and the length of the game. The size of the field depends on the size of the arena. Major indoor arenas are 100 yards (91 meters) long and 50 yards (46 meters) wide. They have goals 10 feet (3 meters) wide and 15 feet (4.6 meters) high marked on opposite ends of the field. The game has four $7\frac{1}{2}$-minute periods. The ball is inflated and is from $12\frac{1}{2}$ to 15 inches (32 to 38 centimeters) in circumference.

Indoor-outdoor polo has won increased popularity in recent years. It is played outdoors, but the players use the same rules that they do in arena polo. The field is 100 yards (91 meters) long and 50 yards (46 meters) wide, and is enclosed by a board fence 4 to $4\frac{1}{2}$ feet (1.2 to 1.4 meters) high. The indoor-outdoor version of polo is popular wherever there is warm weather and a dry climate. Fewer horses are needed for this type of polo than for outdoor polo.

History

Polo may have originated in Persia, now Iran, about 4,000 years ago. The modern game had its beginning in 1862 at Punjab, India, when a group of British officers copied the sport from some tribal horsemen. The game was introduced in England in 1869.

An outdoor polo field is 300 yards (274 meters) long and 200 yards (183 meters) wide. However, if the sidelines are boarded, then the field is only 160 yards (146 meters) wide.

WORLD BOOK diagram

In Egypt, India, and England, polo was played as an outdoor sport. But the first polo game in America was played indoors at Dickel's Riding Academy in New York City in 1876. Polo remained an indoor sport in the United States until 1880, when it became equally popular as an outdoor game. Teams from England and the United States played the first international polo series at Newport, R.I., in 1886. Tommy Hitchcock, Jr., and Cecil Smith are generally considered the greatest United States polo players of all time.

Critically reviewed by the United States Polo Association

See also **Water polo**.

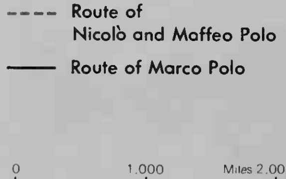
Polo, Marco (1254-1324?), an Italian trader and traveler, became famous for his travels in central Asia and China. He wrote a book that gave Europeans some of their earliest information about China, which was then called *Cathay.*

Early life. Marco Polo was born in Venice. His father, Nicolò Polo, was a merchant. Nicolò and his brother, Maffeo Polo, had left on a trading mission shortly before Marco's birth. Marco's mother died when he was a young boy, and an aunt and uncle raised him. They trained him to be a merchant. Besides reading, writing, and arithmetic, Marco learned about using foreign money, judging products, and handling cargo ships.

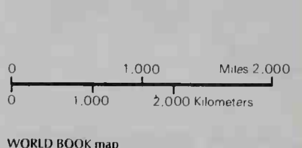
Nicolò and Maffeo Polo returned to Venice in 1269. The brothers had traveled to eastern Asia and had met the Mongol ruler Kublai Khan in China. The Khan had invited them to visit China again, and so they prepared for another expedition—one that would include Marco.

Journey to China. In 1271, Marco Polo—then 17 years old—and his father and uncle sailed from Venice to Acre (now Akko), a port in Palestine. From there, they rode camels to the Persian port of Hormuz, which is now in Iran. The Polos wanted to sail to China from Hormuz, but the ships available there did not seem seaworthy. The travelers continued by camel across the deserts and mountains of Asia. More than three years after leaving Venice, they reached Kublai Khan's summer palace in Shangdu (also spelled Shang-tu), near what is now Kalgan. The Khan gave the Polos a hearty welcome.

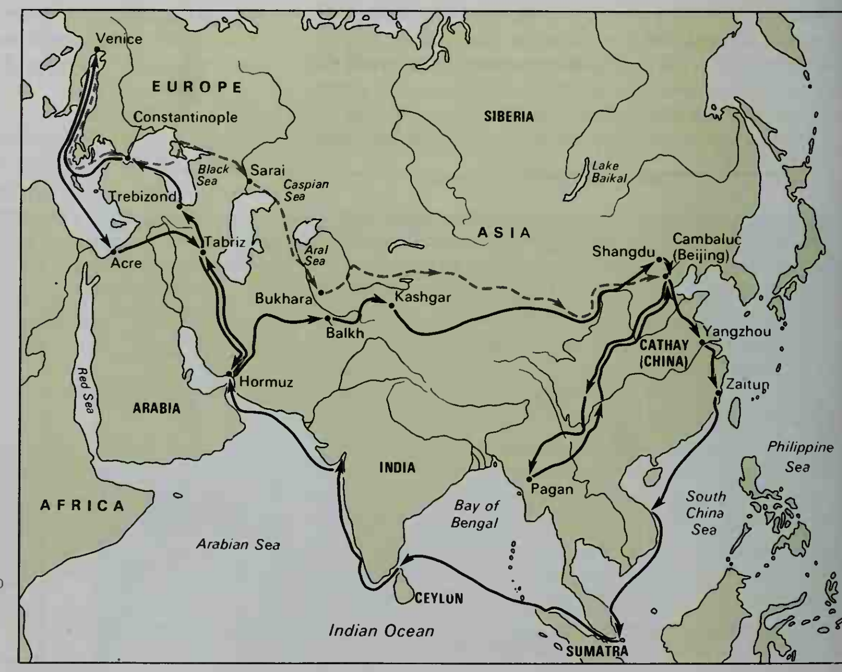
Kublai Khan valued the experience and knowledge of his guests. Marco knew four languages, and the Khan sent him on many official tours of the kingdom. These tours took Marco to China's southern and eastern provinces and as far south as Burma. Marco served as a government official in the Chinese city of Yangzhou (also spelled Yang-chou) for three years.



As time passed, the Polos began to worry about returning home safely. Kublai Khan did not want the Polos to leave China, but they believed that if Kublai Khan were to die before they left China, his enemies might capture them. Finally, in 1292, their chance came. The Khan's great-nephew, the Mongol ruler of Persia, had sent representatives to China to bring him back a bride. The representatives asked the Polos to accompany them on their return to Persia. Kublai Khan reluctantly agreed. That same year, the Polos and a fleet of 14 junks sailed from Zaitun (now Quanzhou, also spelled Ch'üan-chou), a port in southern China.



The fleet sailed to what is now Singapore. From there, it traveled north of Sumatra and then around the southern tip of India. The Polos crossed the Arabian Sea to Hormuz. There, they left the wedding party and traveled overland to the Turkish port of Trebizond (now Trabzon). They sailed to Constantinople and from there to Venice, arriving in 1295. Their journey to China and back probably totaled nearly 15,000 miles (24,100 kilometers). The men had been gone for 24 years.



Later life. The Polos returned from China with many riches. Kublai Khan had given them ivory, jade, jewels, porcelain, silk, and other treasures. When they arrived

The travels of Marco Polo

Marco Polo's father and uncle traveled from Venice to Asia in the mid-1200's. Their route is shown on the map as a dashed line. The Polos, this time accompanied by Marco, set out again for Cathay in 1271 and reached Shangdu in 1274. Marco Polo's travels took him as far as Pagan in what is now Burma. The three Polos stayed in Cathay until 1292 and returned to Venice in 1295. Marco's route is shown as a solid line on the map.

WORLD BOOK map

in Venice, the city was at war with Genoa, its long-time rival. In 1296, the Genoese captured and jailed Marco Polo. Historians do not know the details of his capture. In prison, Polo decided to write about his travels. Aided by his notes, he dictated the story to a popular writer, Rustichello of Pisa. Rustichello translated it into Old French, the literary language of Italy at the time. The book was completed in 1298.

In his book, called *Description of the World,* Polo told about Kublai Khan's prosperous, advanced empire. He described the Khan's postal system, which consisted of a vast network of courier stations. Riders on horseback relayed messages from one station to another.

Polo commented on many Chinese customs, such as the mining and use of coal as fuel. Coal had not yet been used in Europe. Polo called coal *black stones.* He also marveled at the Chinese use of paper money, which bore the seal of the emperor. At that time, Europeans traded with heavy coins made of copper, gold, or lead.

Printing had not yet been invented in Europe, and so scholars copied Polo's book by hand. *Description of the World* was widely read in Europe and may have influenced many explorers. It affected Christopher Columbus's estimate of the distance between Spain and Asia.

Description of the World stimulated European interest in Asia and helped bring to Europe such Chinese inventions as papermaking and printing. Genoa and Venice made peace in 1299. Polo was freed and returned to trading in Venice. John Parker

Macdonald, Fiona. *Marco Polo.* Watts, 1998. Younger Readers.

Polonium, *puh LOH nee uhm,* is a rare, radioactive metallic element. The French physicists Marie and Pierre Curie discovered it in 1898. They named the element in honor of Poland, the country of Marie Curie's birth. Polonium occurs naturally in the uranium ore pitchblende. But most polonium is made artificially by bombarding bismuth, a brittle metal, with neutrons. Scientists use polonium chiefly for nuclear research.

Polonium has the chemical symbol Po. Its atomic number is 84. It melts at 254 °C and boils at 962 °C. Polonium has 27 known isotopes—more than any other element. All of them are radioactive. Its most stable isotope has a mass number of 209 and a half-life of 103 years. During radioactive decay, polonium changes into lead by giving off alpha particles. Raymond E. Davis

Polyandry. See Polygamy.

Polychlorinated biphenyl (PCB), *PAHL ee KLAWR uh NAY tihd by FEHN uhl,* is any of a group of synthetic compounds formed by substituting atoms of chlorine (chemical symbol, Cl) for atoms of hydrogen (H) in a compound called *biphenyl* ($C_6H_5C_6H_5$). A PCB molecule may have from 1 to 10 chlorine atoms.

PCB's once were widely used in the United States in manufactured products. In 1979, however, the United States government prohibited the production of PCB's because of concerns about the effects of PCB's on people. Scientific studies had shown that high concentrations of PCB's may cause birth defects, cancer, liver damage, and nerve disorders. Manufacturers used PCB's in such products as paints and adhesives and in fluids for lubricating industrial machinery. PCB's also were used as insulators in transformers, capacitors, and other electrical equipment. H. Stephen Stoker

Polyester is any of a certain group of widely used plastics materials. One of the main polyesters, *polyethylene terepthalate* (PET), can be spun into fiber, *extruded* (pushed through an opening) to make film, or combined with other materials and molded into plastic parts. PET is a *thermoplastic*—that is, it softens and melts at high temperatures. Polycarbonates are a major group of thermoplastic polyesters (see **Plastics** [Types of plastics]).

Polyesters are synthetic *polymers.* A polymer is a long, chainlike molecule. The "links" are repeating patterns of simple groups of atoms called *monomers.* In most polyesters, the monomers connect to each other by ester groups, units made of one carbon atom and two oxygen atoms.

PET fiber is one of the most widely produced synthetic fibers. It appears in such products as tire cords and clothing. It is strong and flexible, and it resists wrinkling and mildew. Much PET fiber is sold under the name *Dacron,* a registered trademark of the DuPont Company. Uses of PET film include magnetic tapes and shrink wrap. PET is also used to make plastic soft drink bottles, which, like PET film, are clear and tough, and resist water and chemicals.

Other important polyesters are the *unsaturated polyesters.* The monomers in these materials contain *unsaturated acids,* which are hydrocarbon acids with two carbon atoms joined by a double bond (see **Hydrogenation**). Manufacturers use these polymers to make *thermosetting plastics,* which do not soften when heated. Polyester "thermosets" can be combined with *fiberglass* (glass threads) to make a strong rigid material used for automobile body parts, boats, and bowling balls.

Polyester thermoplastics are easy to recycle. The thermosetting materials are difficult to recycle, but can be ground into powders and used as fillers.

Researchers discovered the chemistry of polyesters in the 1930's. In the 1940's, the aircraft industry began to use unsaturated polyesters. In the 1950's, PET fiber became a major product. Marvis E. Hartman

Polyethylene, *PAHL ee EHTH uh leen,* is a major *synthetic polymer,* an essential ingredient of plastics. Polyethylene plastic products include milk jugs, oil bottles, and plastic bags. About a third of all synthetic polymers produced in the United States are polyethylenes.

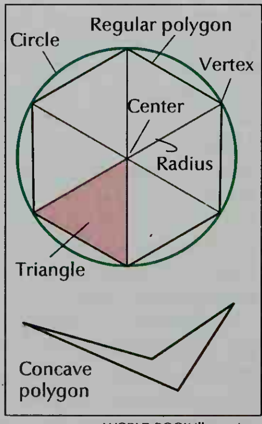
There are three main types of polyethylene: high density polyethylene (HDPE), low density polyethylene (LDPE), and linear low density polyethylene (LLDPE). HDPE is the toughest and most rigid type. Manufacturers form it into such products as bottles and jugs. LDPE and LLDPE are relatively soft and flexible. Manufacturers produce them as thin films. One use of LDPE is as bread bags. Garbage bags are made of LLDPE, which is stronger than LDPE.

A polymer is a long, chainlike molecule. The "links" are repeating patterns of simple groups of atoms called *monomers.* Polyethylene is made from *ethylene* monomers, each consisting of two carbon atoms and four hydrogen atoms. The chemical formula of polyethylene is

$(C_2H_4)_n$, where *n* is the number of monomers.

Manufacturers make polyethylene by mixing a solution of ethylene gas with a *catalyst,* a substance that speeds a chemical reaction without being used up by the reaction. Many polyethylene plastics contain special ingredients, such as colorings and a substance that prevents film from sticking to itself. Polyethylene melts at 230 to 300 °F (110 to 150 °C). It can be melted and reformed again and again, so it is easy to recycle. Imperial Chemical Industries (ICI) of the United Kingdom first produced polyethylene in 1939. Marvis E. Hartman

See also **Plastics** (Diagram: How plastic resins are made); **Polymer.**



Polygamy, *puh LIHG uh mee,* can refer either to a system in which a man is married to more than one woman at the same time, or, less commonly, in which a woman is married to more than one man at the same time. The word *polygamy* comes from two Greek words meaning *many marriages.* Polygyny is a more specific term for the practice of marrying more than one wife. *Polyandry* refers to marrying more than one husband.

Polygyny is much more common than polyandry. Many peoples have practiced polygyny, and some still do, especially in Asia and Africa. The Muslim religion permits marriage between a man and as many as four wives, and the Hindu religion sets no limit on the number of women who may be married to one man. When more than one woman is married to the same man, each wife usually has her own house. The time the husband spends with each wife is usually strictly prescribed. Polygyny was once customary in China and Turkey, but those countries now have laws against it. In the United States, Mormons practiced polygyny until their church made it illegal in 1890. The U.S. Congress had passed a law forbidding polygyny in 1862. But some U.S. families still practice polygyny in the United States, especially in the West. Many of them consider themselves to be following the original Mormon customs.

Polyandry was permitted among the Todas of India and the Inuit (formerly called Eskimos) of the Arctic. Some groups in Tibet still practice it. Jennie Keith

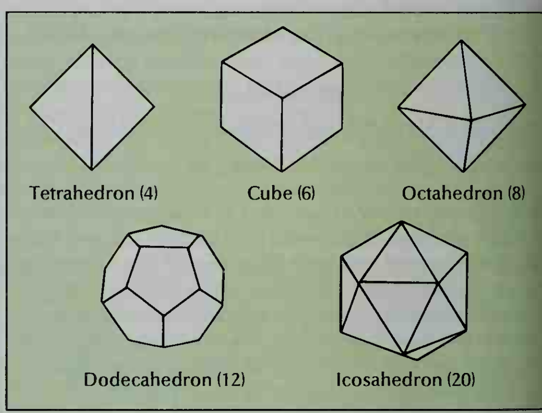
See also **Marriage; Mormons** (Church doctrines).

Polygon, *PAHL ee gahn,* is a closed plane figure composed of a certain number of straight line segments called sides. For example, a polygon that has three sides is a triangle. A polygon with five sides is a pentagon; with eight sides, an octagon. But there are no special names for polygons with a large number of sides, such as ones with 128 or 3,472 sides.

WORLD BOOK illustrations

The end points of a polygon's sides are called *vertexes* or *vertices.* Two sides—and only two sides—meet at each vertex. Those neighboring sides are known as *adjacent sides.* Where these sides meet, they form an angle inside the polygon. Two sides that are not adjacent do not meet at any point.

A polygon is called *equilateral* if all its sides are equal in length. It is *equiangular* if all its angles are equal. A polygon that is both equilateral and equiangular is a *regular polygon.* A regular polygon is a type of *convex polygon.* A polygon is convex if no side, when extended, enters the polygon. A polygon is *concave* if any side, when extended, enters the polygon.



The diagram in this article may help you understand the following three facts about regular polygons: (1) You can draw a circle around a regular polygon so that all of the polygon's vertexes lie on the circle. (2) The center of that circle defines the center of the polygon. (3) Drawing a straight line segment—called a *radius*—from the center of the polygon to each vertex will divide the polygon into identical triangles, one for each side of the polygon.

Deborah Loewenberg Ball and Hyman Bass

See also **Octagon; Pentagon; Triangle.**

Polygraph. See **Lie detector.**

Polyhedron, *PAHL ee HEE druhn,* is a solid figure bounded by four or more flat surfaces called *faces.* Each face of a polyhedron is a polygon. The sides of the polygons form the edges of the polyhedron. The points at which the edges meet are called *vertices.* Examples of polyhedrons include cubes and pyramids. A polyhedron is *convex* if it lies entirely on one side of each of the planes determined by the faces.

WORLD BOOK illustrations

The five regular polyhedrons, with their number of identical faces, are shown here.

A *regular polyhedron,* or *Platonic solid,* is a convex polyhedron in which each face is a *regular polygon* and is identical to all the other faces. A regular polygon has equal sides and equal angles. The five regular polyhedrons are tetrahedrons (4 faces), cubes (6 faces), octahedrons (8 faces), dodecahedrons (12 faces), and icosahedrons (20 faces). John K. Beem

Polymer, *PAHL ih muhr,* is a large molecule formed by the chemical linking of many smaller molecules into a long chain. The small molecular building units are called *monomers.* Monomers are joined into chains by a process of repeated linking known as *polymerization.* A polymer may consist of thousands of monomers. Some polymers occur naturally. Others are synthetic.

Many common and useful substances are polymers. For example, starch and wool are naturally occurring

olymers. Starch is formed by plants from a simple sug-r called *glucose,* and wool is a variety of protein. Nylon nd *polyethylene,* a tough plastic material, are examples f synthetic polymers. Rubber, another polymer, occurs aturally and is also made synthetically.

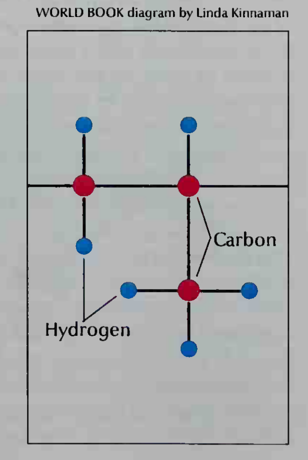
A chain molecule has a definite length, but, like a iece of string, it can assume a variety of shapes. This ombination of molecular length and flexibility gives olymers many useful and unique properties. For exam-le, rubber and numerous other polymers can be retched to several times their normal length without reaking. The chains simply straighten into more ex-nded shapes. Because of the large size of the mole-ules, polymers do not dissolve easily. They also have igh *viscosity* (resistance to flowing). Marvis E. Hartman

See also **Monomer; Viscosity.**

olymorphism, *PAHL ee MAWR fihz uhm,* is the oc-urrence of three or more distinct types of adults in a pecies. For example, there are three types of adult hon-y bees—queen, worker, and drone. Polymorphism is ommon among insects, jellyfish, bacteria, molds, and rotozoans. Breeds and varieties of domesticated ani-als and plants, as well as sexual differences, are not ex-mples of polymorphism. Lawrence C. Wit

olynesia. See **Pacific Islands.**

olyphony. See **Counterpoint.**

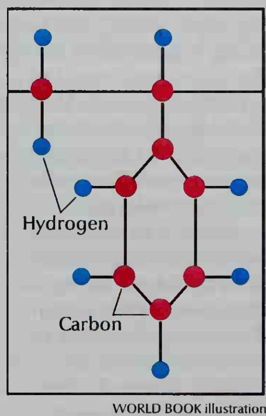


olypropylene, *PAHL ee PROH puh leen,* is a strong, ghtweight, and heat-resistant plastics material. The ma-rial is durable but can be molded into a thin object at bends without breaking. Products made of poly-ropylene include panels for automobile interiors, oatings on telephone wires, carpet fibers, ski apparel, nd containers for such food products as yogurt and argarine.

Polypropylene is a synthetic *polymer.* A polymer is a ng, chainlike molecule. The "links" are repeating pat-rns of simple groups of atoms called *monomers.* Poly-ropylene is made from propylene monomers, each onsisting of three carbon atoms and six hydrogen oms. The chemical formula of polypropylene is $(C_3H_6)_n$, here *n* is the number of monomers. Polypropylene is a *ermoplastic*—that is, it softens and melts at high tem-eratures (see **Plastics** [Types of plastics]).

Manufacturers make polypropylene by mixing propy-ne gas with a *catalyst,* a substance that speeds up a emical reaction without being used up by the reac-tion. They can add pigments to change the color of the material and fillers to make it more difficult to burn or to increase its stiffness. Methods used to shape polypropy-lene products include *extrusion* (pushing melted plastic through an opening), *injection molding* (forcing melted plastic into a mold), and *thermoforming* (using a vacuum to draw hot plastic sheets onto a form).

Giulio Natta, an Italian chemist, developed polypropy-lene in 1954. He shared the 1963 Nobel Prize for Chem-istry with German chemist Karl Ziegler for their work with plastics. Stephen H. Carr



WORLD BOOK diagram by Linda Kinnaman

olypropylene is a synthetic *olymer,* a long, chainlike olecule made of repeating nks" called *monomers.* A olypropylene monomer con-sts of three carbon atoms d six hydrogen atoms.

Polystyrene is a glasslike, lightweight plastics materi-al used in a variety of goods. Products made of poly-styrene include food packaging, insulation, housewares, and automobile parts.

Polystyrene is a synthet-ic *polymer.* A polymer is a long, chainlike molecule. The "links" are repeating patterns of simple groups of atoms called *monomers.* Polystyrene is made from styrene monomers, each consist-ing of eight carbon atoms and eight hydrogen atoms. The chemical for-mula of polystyrene is $(C_8H_8)_n$, where *n* is the number of monomers. Polystyrene is a *thermo-plastic*—that is, it softens and melts at high temper-atures (see **Plastics** [Types of plastics]).

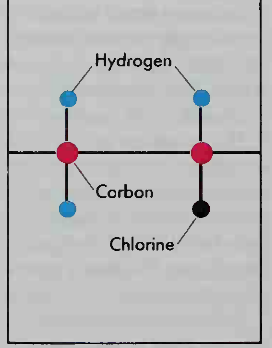
WORLD BOOK illustration

Polystyrene is a synthetic *polymer,* a long, chainlike molecule made up of repeat-ing "links" called *monomers.* A polystyrene monomer con-sists of eight carbon atoms and eight hydrogen atoms.

Polystyrene is fairly strong, easy to work, and inexpensive. A common way to make polystyrene is to heat styrene monomer to about 360 °F (180 °C). Manufacturers produce polystyrene plastics by adding fillers, colorings, and *plasticizers* (chemicals that help soften the material) to the polymer.

A number of methods are used to make products of the plastic. *Extrusion* (pushing melted plastic through an opening) makes a film used in wall coverings. A combi-nation of extrusion and *thermoforming* (using a vacuum to draw hot plastic sheets into a mold) produces food containers and refrigerator parts. *Injection molding* (forcing melted plastic into a mold) creates auto parts and panels for cabinets. *Blow molding* (forcing air and plastic into a mold) produces *polystyrene foam,* a light-weight material containing tiny bubbles of air. This ma-terial is used in ice chests, disposable cups, packaging material, and building insulation.

Polystyrene plastics are difficult to break down into their basic ingredients for recycling. Instead, recyclers grind them into powders that are used as fillers.



Dow Chemical Company became the first producer of polystyrene in 1930. In the mid-1950's, the company in-troduced polystyrene foam under the registered trade name *Styrofoam.* Marvis E. Hartman

Polytheism, *PAHL ee THEE ihz uhm,* is the idea that the sacred appears in many gods rather than in one God.

The belief in one God is called *monotheism.* Hinduism, for example, is a polytheistic religion. There are three main gods in Hinduism and traditionally 33 million other deities as well. But most Hindus accept the idea that behind them all lies a single spiritual entity, often called *Brahman.* The belief that there is a single high God beyond the gods is also found in many tribal religions. Thus, the line between monotheistic religions and polytheistic religions is not absolute. See also **God; Hinduism; Pantheism; Indian, American** (Religion); **Religion** (Belief in a deity). Mark Juergensmeyer

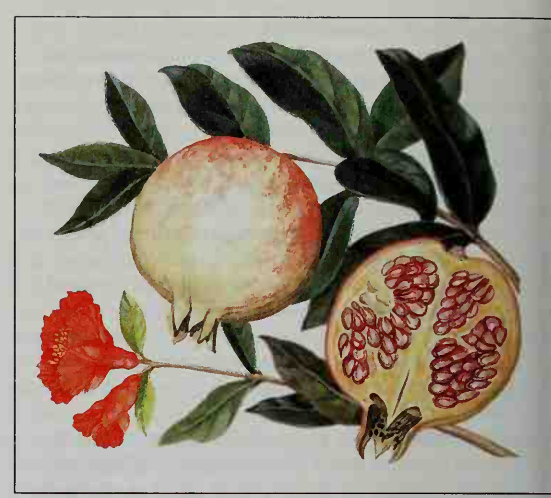
Polyvinyl chloride (PVC) is a strong, durable plastics material. It mixes easily with lubricants, fillers, and colorings to make plastics with many different properties. There are two basic types of PVC plastics—rigid and flexible. Products made of rigid PVC plastic include bottles, pipes, siding, and window sashes. Flexible PVC plastic products include rainwear, shower curtains, garden hoses, and electrical insulation.

PVC is a synthetic *polymer.* A polymer is a long, chainlike molecule. The "links" are repeating patterns of simple groups of atoms called *monomers.* PVC is made from vinyl chloride monomers, each consisting of two carbon atoms, three hydrogen atoms, and one chlorine atom. The chemical formula of polyvinyl chloride is $(C_2H_3Cl)_n$, where *n* is the number of monomers. PVC is a thermoplastic—that is, it softens and melts at high temperatures (see **Plastics** [Types of plastics]).

WORLD BOOK illustration

Polyvinyl chloride (PVC) is a synthetic *polymer,* a long, chainlike molecule made up of repeating "links" called monomers. A PVC monomer consists of two carbon atoms, three hydrogen atoms, and one chlorine atom.

The most common method of making PVC is *suspension polymerization.* In this process, vinyl chloride monomer—a gas—is fed into water under pressure. There, the monomers link to form the polymer.



Manufacturers make PVC plastic products by *extrusion* (pushing melted plastic through an opening), *injection molding* (forcing it into a mold), and *calendering* (pressing it between rollers to form sheets).

Vinyl chloride can also form many *copolymers,* polymers made up of more than one monomer. The most important of these contains vinyl chloride and vinyl acetate. This copolymer is used for floor tiles.

Because PVC plastics contain many ingredients, they are difficult to recycle. However, recyclers commonly grind them into powders that are used as fillers.

The first PVC became available in the late 1920's. Production accelerated during World War II (1939-1945), when PVC was used in synthetic rubber and in insulation for electric wires and cables. Marvis E. Hartman

Pomegranate, *PAHM GRAN iht,* is the fruit of a plant raised in warm climates. The plant grows wild in western Asia and northwestern India. It also is grown commercially in the United States and especially thrives in

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

Pomegranate fruit has a hard rind. The fruit contains many seeds. The crimson pulp is used to make drinks.

the San Joaquin Valley in central California. The plant is bushlike when wild, but under cultivation it is trained to grow as a small tree. It reaches a height of 15 to 20 feet (4.6 to 6 meters) and bears slender branches. Scarlet flowers grow at the ends of the branches.

The fruit is about the size and shape of a large orange and has a hard rind. It has a deep gold-red color. The fruit contains many seeds. Each seed is inside a layer of crimson pulp which has a pleasant, refreshing taste. The pulp is used to make cooling drinks.

The pomegranate was familiar to the Israelites in Biblical times. A picture of it appeared on the pillars of Solomon's Temple. In classic mythology, Persephone was forced to spend one-third of each year in Hades' underworld kingdom because she had eaten pomegranate seeds while living with Hades (see **Persephone**).

George C. Martin

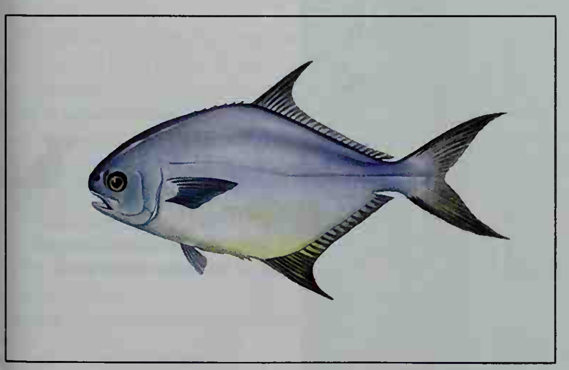
Scientific classification. Pomegranate plants make up the pomegranate family, Punicaceae. The scientific name for the cultivated pomegranate is *Punica granatum.*

Pomeranian, *PAHM uh RAY nee uhn,* is the name of a breed of small dog. The Pomeranian weighs from 3 to 7 pounds (1.4 to 3.2 kilograms), and has a sharp-nosed foxlike face and small, pointed ears. It may be almost any color from black to white, or even orange. It has a soft, fluffy undercoat and a long, thick topcoat with a frill around its neck. Its tail is also thickly covered with hair, and curls up over its back. The dog has a sharp bark. Pomeranians are related to dogs that originally came from the Arctic Circle. However, they first became well known in Pomerania, a former Prussian province in northern Germany. See also **Dog** (picture: Toy dogs).

Critically reviewed by the American Pomeranian Club

Pomo Indians, *POH moh,* were a group of tribes in northern California. The Pomo originally consisted of 72 small tribes that spoke 7 related languages. Each tribe consisted of from 100 to 2,000 people who lived in extended families. Each extended family was led by a hereditary headman or headwoman. Together, these leaders made up the tribe's decision-making body. Each tribe occupied one or more villages. Pomo territory in-

cluded redwood forests along the Pacific coast and grassy foothills around Clear Lake (see **California** [physical map]). For food, the Pomo gathered acorns, berries, bulbs, and seaweed; caught fish and shellfish; and hunted deer, elk, rabbits, and sea lions.



In 1750, there were between 10,000 and 20,000 Pomo Indians. But by 1910, the population had declined to 1,200 as a result of disease and enslavement during Mexican control of the region and as a result of massacres by American settlers. Today, the Pomo live throughout their traditional homeland on reservations and in Ukiah, Santa Rosa, and other towns and cities. Many Pomo work in law, education, and other professional fields. Pomo traditions are kept alive in religious ceremonies, in the creation of basketry art, and in the practice of traditional Pomo medicine. Lee Davis

Pompadour, *PAHM puh DOHR* or *pawn pa DOOR,* **Marquise de,** *mahr KEEZ duh* (1721-1764), was a mistress of King Louis XV of France who played an important part in the politics of Louis's reign. Madame de Pompadour kept her influence long after the king's love for her had cooled. She gave Louis political advice and served as his private secretary. She was blamed for the alliance between France and Austria and France's disastrous involvement in the Seven Years' War (1756-1763). She was also a generous supporter of the arts.

Madame de Pompadour was born in Paris to a middle-class family. Her maiden name was Jeanne-Antoinette Poisson. She received an excellent education and was introduced to high society at the home of Charles-François Le Normant de Tournehem, a wealthy financier. In 1741, she married his nephew Charles-Guillaume Le Normant d'Étoiles. In 1746, she met King Louis at a ball. Louis fell in love with her. She left her husband and went to live in Versailles as Louis's mistress. She received the title Marquise de Pompadour. Maarten Ultee

See also **Louis XV**.

Pompano, *PAHM puh noh,* is the name of a group of valuable food fishes. Several kinds of pompanos are found in the salt waters around North and South America. The *Florida pompano* lives along the Atlantic Coast of the United States and in the seas from the West Indies to Brazil. The Florida pompano is about 1 $\frac{1}{2}$ feet (46 centimeters) long and weighs about 7 pounds (3.2 kilograms). It is bluish above and silvery or slightly golden underneath. The breast is yellowish. The body of the Florida pompano is oblong and flattened from side to side. The flesh of the pompano is highly prized for its rich flavor. Large numbers are caught in nets. Many pompanos are taken on the Florida coasts. The pompano rarely takes a hook.

WORLD BOOK illustration by Colin Newman, Linden Artists Ltd.

The Florida pompano has an oblong body. It is a valuable food fish that lives along the Atlantic Coast.

Another species of pompano is the *palometa,* also called *round pompano.* This fish lives as far north as Cape Cod. It reaches about 1 $\frac{1}{2}$ feet (46 centimeters) in length and weighs about 3 pounds (1.4 kilograms). It is a good food fish. The largest pompano is the *permit,* also called the *great pompano.* The permit grows up to 3 $\frac{3}{4}$ feet (114 centimeters) long and weighs up to 50 pounds (23 kilograms). It lives in the seas from Florida to the West Indies. The permit also is an excellent food fish.

William N. Eschmeyer

Scientific classification. Pompanos belong to the jack family, Carangidae. The scientific name for the Florida pompano is *Trachinotus carolinus.* The palometa is *T. goodei.* The permit is *T. falcatus.*

Pompeii, *pahm PAY* or *pahm PAY ee,* was an ancient city in Italy that disappeared after the eruption of Mount Vesuvius in A.D. 79. For hundreds of years, the city lay buried under cinders, ashes, and stone. Since Pompeii was rediscovered in the 1700's, much has been learned about its history. Each year, excavations in the area around Pompeii bring forth additional bits of ancient art and architecture. Much also has been learned about the everyday life of the ancient Romans and their customs.

Early days. Pompeii was not a remarkable city. But it has become better known than many of the wealthier Roman towns because its ruins were so well preserved. Pompeii lay on a plateau of ancient lava near the Bay of Naples, less than 1 mile (1.6 kilometers) from the foot of Mount Vesuvius. For location, see **Italy** (terrain map).

Scholars have not been able to identify Pompeii's original inhabitants. In the 500's B.C., the area came under the influence of Greek colonies along the coast. A mountain people called the Samnites occupied Pompeii in the 400's B.C. Pompeii remained a relatively unimportant village until the 200's B.C., when the town entered a prosperous period of building and expansion. Pompeii became a Roman community in 91 B.C.

Pompeii was built in the form of an oval about 2 miles (3 kilometers) around. A great wall with seven gates surrounded the city. The streets crossed each other at right angles, and were paved with blocks of lava. Ancient wheel ruts may still be seen in the pavements. In the center of the city was the open square, or forum. It was surrounded by a group of important buildings. The city had a theater, an amphitheater, a gladiators' court, many temples, and three large public baths.

The fair blue skies of Pompeii attracted many wealthy Romans. They built great *villas* (homes) near the Mediterranean shore, where they could enjoy the mild, sunny climate. The Pompeians built their villas with all the conveniences of a town in country surroundings. The large dwellings often consisted of two parts, the master's house and gardens, and the farmer's house with stables, barns, orchards, and fields. Most dwellings were built along the lines of a typical Roman house, with rooms grouped around the *atrium* (reception room). Town houses in Pompeii often had shops bordering the street. Archaeologists believe that most buildings had more than one story. The upper parts of the

buildings may have been constructed partly of wood. They projected out over the street, like French and English houses of the Middle Ages.

Pompeii carried on a prosperous trade in wine, oil, and breadstuffs. The city was a market for the produce of a rich countryside, and its port had widespread connections in the Mediterranean area. Pompeii was also an industrial center and produced such specialties as millstones, fish sauce, perfumes, and cloth. Inhabitants of Pompeii included wealthy landowners, prosperous merchants and manufacturers, shopkeepers, artisans, and slaves.

The eruption of Mount Vesuvius. Earthquakes in A.D. 62 or 63 damaged Pompeii, Naples, and Herculaneum. Statues fell, columns were broken, and some buildings collapsed. Mount Vesuvius rumbled at this time. However, the people did not believe that there would be more danger, and they repaired their cities. During the summer of A.D. 79, Vesuvius erupted suddenly and with great violence. Streams of lava and mud poured into Herculaneum and filled the town and its harbor.

Hot ashes, stones, and cinders rained down on Pompeii. The darkened air was filled with poisonous gas and fumes. The Roman writer Pliny the Younger told in a letter how he led his mother to safety through the fumes and falling stones. His uncle, the writer Pliny the Elder, commanded a fleet that rescued some people. He landed to view the eruption and died on the shore.

The remains of about 2,000 victims out of a population of some 20,000 have been found in excavations at Pompeii. Some of the victims were trapped in their homes and killed by hot ashes. Others breathed the poisonous fumes and died as they fled. Archaeologists find the *shells* (molds) of the bodies preserved in the hardened ash. By carefully pouring plaster into the shells, they can make detailed copies of the individuals, even to the expressions of agony on their faces.

Rather than the lava, showers of hot, wet ashes and cinders sprayed Pompeii. When these ashes and cinders dried, they covered and sealed up much of the city. Only the tops of walls and columns emerged above the waste. Survivors dug out valuables they had left behind and even took statues, marbles, and bronzes. However, later eruptions and erosion erased the last traces of the city.

The eruption of Vesuvius destroyed not only Pompeii but also the nearby cities of Stabiae and Herculaneum (see **Herculaneum**). The eruption changed the entire geography of the Campania region around Pompeii. It turned the Sarno River back from its course and raised the sea beach so there was no way of locating Pompeii, which lay beneath the ash deposits for almost 1,700 years.

Excavations. The buried city was not completely forgotten. Peasants living in the area searched for hidden treasure. They did not excavate openly, but they tunneled into the deposits and reached houses. In the 1500's, workers digging an underground tunnel to change the course of the Sarno River discovered parts of the amphitheater, forum, and a temple. But no one paid much attention to these finds.

In 1748, a peasant was digging in a vineyard and struck a buried wall. His discovery was brought to the attention of authorities in Italy, and soon people began to carry on excavations in the region. At first, the diggers hoped to recover objects that would enrich the museums of the kings of the Two Sicilies. For about 100 years, the search concentrated on important buildings, such as the forum, the amphitheater, the theater, and the larger houses.

After 1860, Giuseppe Fiorelli served as director of the excavations. He instituted the first systematic uncovering of the whole city block by block. In the early 1900's, archaeologists decided not to remove treasures from the city, but to keep them and to restore buildings as much as possible to their original condition. The Italian government has given money for this work.

Remains. Approximately three-fourths of Pompeii has now been uncovered. Visitors may view buildings as they stood almost 2,000 years ago. They may walk in and out of houses and up and down narrow lanes, just as the Pompeians did. They may see the ruins of the ancient public square, with many of the surrounding buildings.

Visitors also may see the old Temple of Jupiter, which was an ancient ruin at the time of the eruption of Vesuvius. They may wander through the old Roman public

Fred M. Dole, FPG

Mount Vesuvius looms in the background over the once-thriving city of Pompeii. The cinders and ashes that buried the city aided in preserving its ruins for almost 2,000 years. About three-fourths of Pompeii has been uncovered.

halls, and admire the temples of Apollo and Fortuna Augusta.

Workers have uncovered a large part of the city wall. The disaster occurred during a local election campaign. Election slogans can still be seen on the walls of houses. Not many valuables have been found. Historians believe that the Pompeians carried many of their possessions with them as they fled from the city. Workers have found bracelets, earrings, gems, and coins. They have also discovered household statues of silver, bronze, and ivory, as well as utensils of metal and glass. Many domestic treasures came to light near Boscoreale, a town near Naples. A large number of Pompeian objects are on display in the National Archaeological Museum at Naples, approximately 13 miles (21 kilometers) from Pompeii. Erich S. Gruen

Pompey the Great, *PAHM pee* (106-48 B.C.), was an outstanding Roman general and statesman. He was the last obstacle in the rise to power of Julius Caesar.

Pompey was born on Sept. 29, 106 B.C., in Rome, the son of a prominent nobleman. He grew up during the war between Gaius Marius and Lucius Sulla, and in 83 B.C. raised his own army of three legions to help the aristocrat Sulla against the forces of Marius in Italy. Then he wiped out the supporters of Marius in Sicily and Italy.

When Sulla died in 78 B.C., the consul Marcus Lepidus tried to repeal his conservative reforms. But Pompey opposed him and drove him out of Italy. The Senate then sent Pompey to Spain to put down an army of Marius's supporters, who were led by Sertorius. After Sertorius was murdered by his own men, Pompey won an easy victory and returned to Rome in 71 B.C.

The conservative group in Rome did not wish to see Pompey gain further glory, but he was elected consul in 70 B.C. He broke with the conservatives and restored the powers of the tribunes that Sulla had taken away. Through popular support, Pompey was given the task, in 67 B.C., of clearing the Mediterranean Sea of pirates. In 66 B.C., he fought Mithridates of Pontus. Pompey defeated him and conquered eastern Asia Minor, Syria, and Palestine.

The Senate refused to approve his acts in Asia and his promises of land to his troops. So Pompey, Julius Caesar, and Marcus Crassus formed the First Triumvirate in 60 B.C. (see **Triumvirate**). They worked together against the Senate for several years. But Pompey became fearful of Caesar's ever-increasing power, and turned back to the conservatives. In the resulting civil war, Pompey was defeated in Italy and again at Pharsalus in Thessaly in 48 B.C. He escaped to Egypt, but was killed there by order of the Roman-dominated Egyptian government.

Ponce de León, *PAWN say day lay AWN,* or *PAWNS duh LEE awhn,* **Juan,** *hwahn* (1460?-1521), a Spanish explorer, led the first recorded European expedition to reach what is now Florida. He was one of the first explorers to claim part of the North American mainland for Spain. He also conquered what is now Puerto Rico and became its first colonial governor.

According to a popular fable, Ponce de León came to Florida to find a spring called the Fountain of Youth. Old stories said that the waters of the spring were supposed to restore youth and cure sickness. But historians believe that even though Ponce de León may have heard stories about a Fountain of Youth, he was actually interested in finding wealth and new lands that he could govern.

Early life and career. Little is known about Ponce de León's early life. He was born in Santervás de Campos, near the Spanish town of Palencia. He came from a noble family and served as a page in the Spanish court.

Ponce de León reportedly fought in the long Spanish campaign that in 1492 finally drove the *Moors* (Spanish Muslims) out of Granada, their last stronghold in Spain. Most historians believe that he then joined the vast second expedition of the famous explorer Christopher Columbus. The fleet reached Hispaniola, a Spanish island in the West Indies, in 1493. Ponce de León may have then gone back to Spain before returning to Hispaniola in 1502. However, some historians think he did not sail with Columbus but instead may have first come to Hispaniola in 1502.

Ponce de León became a soldier on Hispaniola and led Spanish forces against the Indians in the eastern province of Higüey (now part of the Dominican Republic). He founded the town of Salvaleón, where he built a residence and invested in mining and agricultural enterprises.

In 1508, Ponce de León left Hispaniola to explore the island of San Juan (later renamed Puerto Rico). He discovered gold there and conquered the island. He became governor of the island in 1509.

Florida expeditions. In 1512, King Ferdinand chose Ponce de León to lead an expedition to find and colonize an island called Bimini that the Spaniards thought lay north of Cuba. Ponce de León set sail for Bimini with three ships in 1513. During the voyage, he explored the

Juan Ponce de León in 1513 led the first European expedition to what is now Florida. On the return voyage, Ponce de León probably landed on the north coast of Cuba.

area of the Bahamas. On April 2, 1513, he anchored off the coast of Florida—which he thought was another island—and claimed it for Spain. He probably named the land *La Florida,* because he arrived there during the season of Easter, which the Spaniards called *Pascua Florida* (Easter of the Flowers).

The explorers landed on the east coast of Florida, probably somewhere between present-day St. Augustine and Cape Canaveral. From there, they sailed down the coast, exploring almost the entire eastern shoreline and the southern tip of Florida. They swung around the Florida Keys and then continued partway up Florida's western coast. The Europeans made a temporary base near present-day Fort Myers. They fought several battles in this area with the Calusa Indians.

In May 1513, Ponce de León began a roundabout trip back toward Puerto Rico. He probably stopped on the north coast of Cuba. He sailed by the Bahamas again before he returned to Puerto Rico in the fall.

In 1514, Ponce de León sailed to Spain to press his claims to the Florida territories. King Ferdinand authorized him to colonize Bimini and Florida. But the king also ordered him to stop the attacks by Carib Indians on the Spanish colonies in Puerto Rico. Ponce de León returned to Puerto Rico in 1515 to fight the Carib. However, King Ferdinand died in 1516. Ponce de León soon returned to Spain, where his authorization to make a second expedition to Florida was renewed.

In February 1521, Ponce de León sailed from Puerto Rico with two ships carrying as many as 200 settlers and supplies to establish a colony. They probably landed near the place where the first expedition had encountered the Calusa. The Calusa again put up a stiff resistance against the Spaniards. Ponce de León was wounded, and the colonists decided to turn back. Ponce de León died from his wounds shortly after the fleet reached Cuba. Noble David Cook

Pond is a small, quiet body of water that is usually shallow enough for sunlight to reach the bottom. The sunlight enables rooted plants to grow across a pond bottom from shore to shore.

In many regions, ponds have a great variety of animal and plant life. The wind and streams carry in eggs, seeds, and organisms that develop into various forms of life. Pond animals include birds, crayfish, fish, frogs, insects, and turtles. Many ponds have rooted plants that either grow entirely underwater or have parts that extend above the surface. Leafy plants float on the surface. Microscopic organisms also thrive in most ponds.

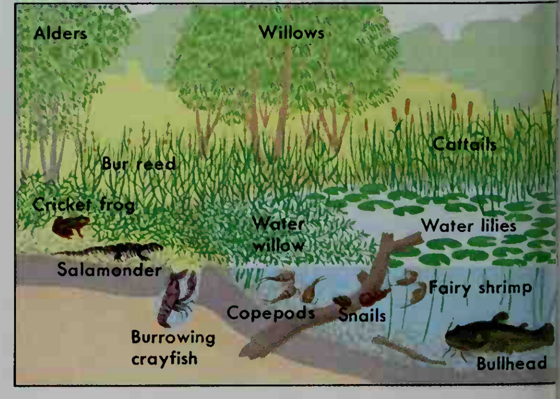
Pond life. The plant and animal life found in a pond are determined largely by the pond's soil, quality of water, and location. Tropical ponds have different species of plants and animals than ponds in the Arctic, in mountains, or in prairies.

Ponds constantly undergo annual and long-term changes. Water levels normally rise and fall because of rainfall. As water levels change, the type and amount of plant growth also change. As the numbers and types of plants change, some animals may become numerous while others may decline in numbers.

Many natural processes help to maintain ponds. For example, floods and the movement of ice may deepen ponds. Human activities, on the other hand, can seriously harm ponds. For example, the quality of a pond rapidly deteriorates when people fill it with garbage or other wastes.

Kinds of ponds. Ponds may be formed by natural conditions or by human beings. The chief kinds of natural ponds include *alpine ponds, bog ponds, ice-formed ponds, meadow-stream ponds, riverine ponds, sinkhole ponds,* and *tundra ponds.* Many farmers build a *farm pond* for flood control or recreation, or to secure a supply of water.

Alpine ponds are gouged out by glaciers in mountainous regions. Many are located in the Alps in Europe and the Rocky Mountains in the United States.



Bog ponds form worldwide, but especially in low-lying places in cooler regions of the Northern Hemisphere. These ponds contain much peat and peat moss. The water of bog ponds has a high acid content.

Ice-formed ponds were created during prehistoric times by sheets of ice that crossed large regions of the world, particularly in the Northern Hemisphere. The scraping action of these sheets caused many basins that became ponds.

The life of a pond The life of a pond changes as the water level changes. In a pond with high water, *left,* plants are less dense and animals that live best in open areas are abundant. When water is low, *right,* plants cover more of the pond surface and animals that thrive in dense plant growth are more common.

Meadow-stream ponds develop where a slowly moving stream widens as it flows over a gently sloping landscape. Most meadow-stream ponds contain abundant life.

Riverine ponds develop where streams have stopped flowing through old channels. These ponds also occur where deposits of soil prevent water from entering channels.

Sinkhole ponds develop in regions that have much limestone beneath the surface of the soil. If underground water dissolves the limestone, the ground sinks and a pond may form. Florida and Indiana have many sinkhole ponds.

Tundra ponds form in regions that have *permafrost* (permanently frozen ground). In such regions, areas of thawed ground may become ponds.

Pontiac, *PAHN tee AK* (1720?-1769), a chief of the Ottawa tribe, was an important American Indian leader during the 1760's. Pontiac tried to unite the tribes of the Great Lakes area and of the Ohio and Mississippi valleys in order to maintain Indian control of those regions.

During the French and Indian War (1754-1763), Pontiac led his tribe in fighting with the French against the British. But he opposed the claims of both sides to the territory west of the Allegheny Mountains. After the British achieved major victories over the French in 1760, they sent a small force to take over the abandoned French forts near the Great Lakes. Pontiac let the British pass through the area. But after he got promises of help from French traders and officers, he made plans with other tribes of the region to attack the posts.

In the spring of 1763, the tribes captured nine British forts in what became known as Pontiac's War. Pontiac led the attack on Fort Pontchartrain, at what is now Detroit. He besieged the post for about five months. However, France sent no help to Pontiac and his forces, and the Indians could not continue the war without more guns and ammunition.

Bettmann Archive

Pontiac

Pontiac was probably born in northern Ohio. He became a priest of a religious group called the Midewiwin, or Grand Medicine, Society. Pontiac agreed with the Indian holy man known as the Delaware Prophet, who preached that Indians should abandon all trade with white people. Pontiac was mysteriously killed at an Indian religious center located in Cahokia, Ill. Rhoda R. Gilman

Pontoon bridge is a bridge supported by *pontoons* (flat-bottomed boats), metal cylinders, or other portable floats. A pontoon bridge is sometimes called a *ponton* bridge. A flooring of timber or lightweight metal panels is usually laid across a pontoon bridge.

Pontoon bridges are especially important during wartime. These bridges are built to replace those that have been destroyed by enemy forces. Special pontoon-laying troops bridge streams with mechanical exactness, even under fire. The soldiers lay the flooring, section by section, fastening it securely to the pontoons. Pontoon bridges are usually of limited strength, though sufficient to carry ordinary road vehicles. Soldiers must break step in crossing them to prevent the swaying of the bridge caused by marching in time.

The importance of pontoon-bridge building was shown in Europe during World War II. Retreating troops blew up many bridges across important rivers. Engineers of pursuing armies built pontoon bridges, permitting troops and mechanized equipment to cross the rivers.

In the United States, pontoons have been used for permanent bridges in places where deep water makes pier construction too expensive. Three large concrete floating bridges have been built in Washington. One of these has the longest floating span in North America. This span stretches 7,518 feet (2,291 meters) across Lake Washington. Boyd C. Paulson, Jr.

Pony. See **Horse** (Ponies); **Shetland pony**.

Pony express was a mail delivery service that operated between St. Joseph, Mo., and Sacramento, Calif., in 1860 and 1861. The pony express consisted of relays of men riding fast ponies or horses that carried letters and small packages across a 1,966-mile (3,164-kilometer) trail. These riders could deliver mail to California in 10 days or less, faster than any other mail service of that time. Previously, mail traveled between California and areas east of the Mississippi River only by boat or stagecoach. A one-way delivery between the farthest points took more than three weeks.

Early in 1860, Senator William M. Gwin of California and William H. Russell, a Missouri businessman, agreed to establish an express mail service between St. Joseph and the west coast. St. Joseph then served as the western terminal of the nation's railroad system. Russell's large freighting firm—Russell, Majors, and Waddell—backed the project.

Russell and his associates collected about 400 fast horses, hired approximately 80 riders, and established 190 pony express stations. These stations stood 10 to 15 miles (16 to 24 kilometers) apart. The pony express route ran along the Platte River in what is now Nebraska, to South Pass and Fort Bridger, both now in Wyoming. Then it turned south to the Great Salt Lake. South of Salt Lake City, it headed west across the salt desert to the Sierra Nevada. The pony express began its first run on April 3, 1860. At first, it charged $5 to send half an ounce (14 grams) of mail. The rate later fell to $1 for half an ounce.

Only young, lightweight men served as pony express riders. Many of them were teen-agers. A day's work consisted of a trip of 75 miles (121 kilometers) or more. The rider mounted a fresh horse at each station along the trail. He ended his workday when he reached a *home station,* where another rider took his place. Pony express riders were paid from $100 to $150 a month.

Oil painting on canvas (1900); Thomas Gilcrease Institute of American History and Art, Tulsa, Oklahoma

A pony express rider switches to a fresh mount and begins another step of his dangerous dash across the West. The American artist Frederic Remington captured this scene in his painting *The Coming and Going of the Pony Express.*

The rider carried mail in a specially designed leather saddlebag. The saddlebag fit over the saddle, and only the rider's weight held it in place. As a result, the rider could change horses in about two minutes.

The pony express typically forwarded mail at a rate of more than 200 miles (321 kilometers) a day. The fastest run between St. Joseph and Sacramento came in March 1861. That month, a copy of President Abraham Lincoln's first address to Congress arrived in Sacramento just 7 days and 17 hours after leaving St. Joseph.

The pony express ran day and night. Riders worked in all kinds of weather and faced the threat of Indian attacks. Most of the riders carried a pair of pistols and a knife. Only one rider in the history of the pony express was killed by Indians.

The transcontinental telegraph ended the major need for the pony express. It opened on Oct. 24, 1861, and the pony express officially closed two days later. Russell's freighting firm lost more than $100,000 on the pony express. Odie B. Faulk

Poodle, *POO duhl,* is the name of a breed of smart, friendly dogs. The poodle was once used as a hunter and retriever, but it is no longer classed as a sporting dog. The breed originated in Germany during the 1500's. Today, poodles are very popular as pets throughout the world.

Poodles may be white, black, gray, blue, brown, or apricot. Their hair is curly or frizzy, and the coat is usually clipped in any of several styles. The three varieties of poodles are classified by shoulder height. The *toy poodle* is 10 inches (25 centimeters) or under; the *miniature poodle* is between 10 and 15 inches (25 to 38 centimeters); and the *standard poodle* is over 15 inches at the shoulder. Poodles weigh from 3 to 60 pounds (1.4 to 27 kilograms).

Critically reviewed by the American Kennel Club

Poor Richard's Almanac was an almanac written and published by Benjamin Franklin. The famous American statesman created the almanac early in his career, when he was a printer and publisher in Philadelphia. He issued the almanac for every year from 1733 to 1758.

Franklin wrote the almanac under the name of Richard Saunders, an imaginary astronomer. Like other almanacs of its time, *Poor Richard* included such features as astrological signs, practical advice, jokes, poems, and weather predictions. At first, Richard had little wit or humor. But as he developed, he became a clever spokesman for Franklin's ideas on thrift, duty, hard work, and simplicity. *Poor Richard's Almanac* grew

Can Tif's Poodles (DAG Photo)

The standard poodle is one of three varieties of this popular pet breed. It has a curly coat shown clipped here.

into one of the most popular and influential works printed in colonial America. Franklin published the almanac under his own name. In each edition, Richard offered his readers a number of proverbs. Many of these sayings became famous, including:

"A penny saved is a penny earned."
"God helps them that help themselves."
"Early to bed and early to rise,
Makes a man healthy, wealthy, and wise."

Such proverbs expressed Franklin's philosophy that foresight, wise spending, and plain living are not only good qualities, but also lead to success. This philosophy greatly influenced American thought before and after the Revolutionary War (1775-1783).

Franklin enlarged the almanac for the 1748 edition and called it *Poor Richard Improved.* In the preface to the final edition, published in 1757, he collected many of Richard's proverbs on how to succeed in business and public affairs. The preface, called "The Way to Wealth," was reprinted separately and was widely read in England and France as well as in America. However, this collection of proverbs provides a misleading view of Franklin's wisdom and character because it focuses chiefly on material gain and proper conduct. Many of Franklin's other sayings reveal that he also had a witty and sometimes skeptical mind. Edward W. Clark

Pop. See **Soft drink.**

Pop art is an art movement that originated in England in the 1950's but became best known in the United States during the 1960's. Many pop artists use common, everyday, "nonartistic" commercial illustrations as the basis of their style or subject matter. Many of the works these artists produce are satirical or playful in intent. However, their uses of forms and themes from mass culture are intended to devalue what they consider to be unnecessarily difficult and private aspects of traditional fine art forms.

Pop artists have no single way of working. Some are fascinated by the bold, simple patterns of commercial illustrations. For example, Andy Warhol made exact painted copies of soup cans, repeating them over and over in the same painting. James Rosenquist and Tom Wesselmann use advertising art as the basis of paintings with their own complex, often humorous and frequently critical designs. Several pop artists have made three-dimensional constructions that resemble and embrace the world of ordinary objects. Stephen C. Foster

Wallraf-Richartz-Museum, Cologne, Germany, Ludwig Collection (Ann Münchow)

Pop art painting, like the comic-strip panel *M-Maybe* (1965) by Roy Lichtenstein, shows the influence of commercial art.

Popcorn is a type of corn that is a popular snack food in the United States. Popcorn has smaller kernels than other types of corn, and the kernels are very hard. Popcorn is a good source of dietary fiber and, when eaten plain, is low in calories.

A popcorn kernel has a hard outer shell that surrounds a soft, moist, starchy center. When a kernel is heated, its moisture turns rapidly to steam. The steam builds up pressure inside the shell until the shell bursts. The steam is quickly released with a small explosion that turns the kernel inside-out. The soft center expands and becomes filled with air. Popcorn pops best when kernels contain about 13.5 per cent moisture. Kernels expand to 30 to 40 times their original size when popped.

Popcorn is probably native to Central America and is one of the oldest forms of corn. American Indians grew popcorn for more than 1,000 years before the arrival of European explorers in the 1400's and 1500's. Indians used popcorn for food, for decoration, and in religious ceremonies. Today, the United States grows nearly all the world's popcorn. Indiana, Nebraska, and Illinois lead the states in popcorn production.

Scientific classification. Popcorn belongs to the grass family, Poaceae or Gramineae. Its scientific name is *Zea mays everta.*

Donald J. Reid

Popé, *poh PAY* (? -1688?), was a Pueblo Indian leader. He helped plan and lead a major Pueblo revolt against the Spaniards in what is now New Mexico. Spanish explorers had come to this area about 1540. Through the years, they tried to convert the Indians to Roman Catholicism. They forced the Indians to work for them and to pay taxes with crops. In 1680, Popé helped lead a Pueblo revolt that drove out the Spaniards and kept them from the Indians' land for 12 years.

After the revolt, Popé became the leader of several Tewa Pueblo villages. He tried to remove all traces of Spanish influence from Pueblo life. But Popé often used harsh punishments to enforce his rule. In 1688, the villages he controlled forced him from power. Popé died shortly after regaining the leadership of several Pueblo villages later that year.

Popé was born in the pueblo of San Juan, near what is now Santa Fe, N. Mex. His Indian name was *Po-ṕng,* which means Pumpkin Mountain. Joe S. Sando

UPI/Bettmann Newsphotos

The pope is the spiritual leader of millions of Roman Catholics throughout the world. He also rules Vatican City, an independent country within the city of Rome. Each Christmas Day, thousands of people gather in St. Peter's Square in Vatican City, *shown here,* to receive the pope's blessing.

Pope

Pope is the head of the Roman Catholic Church. The church regards the pope as its visible head and Jesus Christ as its invisible and supreme head. Roman Catholics believe that Jesus established the office of pope when He said to the apostle Simon, who was also called Peter:

> And I say also unto thee, That thou art Peter, and upon this rock I will build my church; and the gates of hell shall not prevail against it (Matt. 16:18).

Except for brief periods of vacancy, there has been an unbroken line of popes beginning with Peter. John Paul II, who became pope in 1978, is generally considered the 264th pope.

The word *pope* comes from the Greek word *pappas,* which is a child's name for its father. The pope is also called the *pontiff,* from the Latin word *pontifex,* a term used for a member of the council of priests in ancient Rome.

The word *papacy* refers to the office of the pope. It is also used for the government of the Roman Catholic Church with the pope as supreme head. The papacy is also called the *Holy See* or *Apostolic See. See* is a term for the official home of a bishop. *Holy See* is especially used as a term for the papacy when referring to its functions and *jurisdiction* (authority).

In the early history of the church, bishops in general were often called pope. Beginning in the early 500's, the title in the Western church came to be used exclusively for the bishop of Rome. According to tradition, Peter traveled to Rome and became the city's first bishop, giving special status to Rome and to its office of bishop. The pope lives in the Vatican Palace in Vatican City, an independent country that is located within the city of Rome.

The pope is elected for life. He can resign, but he cannot be *deposed* (forcibly removed from office). Officially, any practicing Roman Catholic male is eligible to be elected pope. However, since the 1300's, the pope has always been chosen from among high-ranking clergymen called *cardinals.* Together, the cardinals make up the Sacred College of Cardinals, and serve as the pope's chief advisers.

Almost all popes have been Italian. In 1978, John Paul II became the first non-Italian pope since 1523. John Paul was born in Poland.

The powers of the pope

The pope has two basic types of powers: *spiritual* and *temporal.* Spiritual powers are concerned with faith, morals, religious practices, and church government. Temporal powers involve the civil administration of Vatican City as an independent state.

Roman Catholics believe that the pope is *infallible* (incapable of error) when he speaks for all the church on matters of faith and morals. The pope is not considered infallible on other aspects of church affairs. However, he

does have absolute jurisdiction. For example, he can make laws for the entire church. He appoints cardinals, appoints or removes bishops, establishes and divides *dioceses* (church districts headed by bishops), and approves new religious *orders* (brotherhoods or sisterhoods).

For a period during the Middle Ages, the pope exercised considerable temporal, as well as spiritual, power. From 756 to 1870, the papacy controlled provinces and cities in central Italy, including Rome, called the Papal States. Today, the pope's temporal responsibilities are limited to ruling Vatican City, the smallest independent country in the world. Vatican City has an area of 109 acres (44 hectares) and a population of about 1,000. It has its own flag, coins, stamps, public works, and communications systems. The pope sends representatives, called *nuncios,* to other independent states and receives foreign diplomats.

As the leader of hundreds of millions of Roman Catholics around the world, the pope can speak as an influential international leader. Popes have spoken on a variety of religious and *secular* (nonreligious) subjects. Modern popes have issued strong, sometimes controversial, statements on such political issues as government tyranny, and on birth control and other matters involving the family.

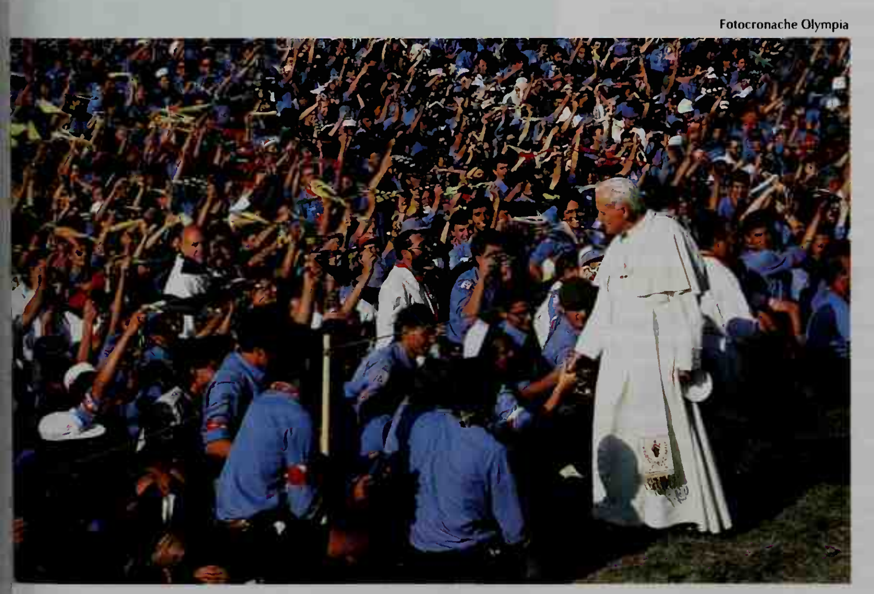
Paul VI officiating at a Mass (Fotocronache Olympia)

The pope's vestments for saying Mass include a white skullcap, a woolen collar called a *pallium,* and a sleeveless garment called a *chasuble* worn over a long white cassock.

Titles, clothing, and symbols

The pope is addressed as "Your Holiness." He speaks of himself in official documents as "servant of the servants of God." Each man who is elected pope traditionally takes a new name for use during his reign. Most popes choose the name of an earlier pope whom they admire.

Like other clergy, the pope wears distinctive religious clothing called *vestments.* In general, his garments are the same style as those worn by a bishop. The pope's everyday clothing includes black trousers, a collarless white shirt, a clerical collar, a white skullcap, and a long white garment called a *cassock* with a sash. For public appearances, the pope may wear a short red cape called a *mozzetta;* and a circular collar of white wool, called a *pallium,* which rests on the shoulders. The pallium is embroidered with six black crosses. The pope also wears low red shoes.



The pope wears a cross made of gold, called a *pectoral cross.* The pope's jewelry also includes a ring known as the *fisherman's ring.* It shows Peter in his occupation as a fisherman and symbolizes the pope's role as a "fisher of men."

The daily life of the pope

The pope lives in the Vatican Palace most of the year. During the summer, he moves to the papal villa in the small town of Castel Gandolfo in the Alban Hills southeast of Rome. This section describes a typical day in the life of John Paul.

The pope rises each morning by 6 a.m. The pope's

Fotocronache Olympia

The daily life of the pope includes meeting with groups of Roman Catholics who visit Rome. In this picture, John Paul II greets a gathering of Boy Scouts. The pope also holds regular receptions called *audiences* in Vatican City for visitors.

simply furnished bedroom has a bed with a red, hand-embroidered bedspread and a desk where the pope does most of his writing. The room also has a kneeler that the pope uses for private prayer.

After dressing and completing his private prayers, the pope is met at his bedroom by two priest-secretaries who escort him to a nearby papal chapel where he says Mass. John Paul often invites guests to this 7 a.m. Mass.

After breakfast from 8:30 to 9 a.m., the pope meets with two assistants, called *prefects,* who brief him on his daily schedule and diplomatic developments. John Paul then attends meetings and handles paperwork before holding private *audiences* (receptions) that begin at 11 a.m. Visitors to Rome and people who have business with the Holy See attend these audiences, which last 15 to 20 minutes. The pope also holds a general audience every Wednesday that may attract up to 12,000 people indoors and 40,000 outdoors in St. Peter's Square in Vatican City.

Lunch with guests is served about 1:30 or 2 p.m. After lunch, the pope rests for 30 minutes and then goes to the roof garden above his apartment in the Vatican Palace for some fresh air and a bit of walking. Earlier in his reign, John Paul enjoyed brisk walking, jogging, swimming, and skiing. However, the effects of an assassination attempt, surgery for a colon tumor, a hip injury, and aging have reduced his physical activity.

The pope works alone until 6:30 p.m. Then he meets various Vatican officials, such as his secretary of state, until dinner is served at 8 p.m. If there are dinner guests, they will be Vatican officials. If there are no guests, the pope watches television news during dinner and then perhaps a soccer game or a motion picture. After more time in his study, John Paul makes a final visit to the chapel at 11 p.m. for night prayers called *compline.* He then goes to bed.

The first Saturday of each month, the pope leads a recitation of the rosary over the Vatican radio. He schedules visits to local parishes in Rome on many Sundays.

The election of a pope

Early days. During the history of the papacy, procedures for electing a new pope have varied. Until the 300's, popes were elected by a kind of local election involving clergy from Rome and nearby areas. For many centuries, kings, emperors, and other secular leaders interfered in the election process and tried to influence the outcome. At various times, an *antipope* set himself up in opposition to the pope who had been elected legally. An antipope is a man determined to have improperly claimed to be or served as pope. Sometimes emperors or factions within the church itself supported antipopes.

Major features of the present electoral procedure date back to 1059, when Pope Nicholas II (1059-1061) declared that papal electors must be cardinals. In 1179, Pope Alexander III (1159-1181) presided over the Third Lateran Council, which established that all cardinals had an equal vote and election required a two-thirds majority. In 1274, Pope Gregory X (1271-1276) took steps to prevent election delays by requiring all cardinals to meet within 10 days of a pope's death. They had to remain together in strict seclusion from the outside world until they elected a new pope. By the late 1500's, most electoral procedures now in effect had been adopted.

Present procedures. When a pope dies, the dean of the Sacred College notifies all cardinals of the vacancy. They are called to a *conclave* (meeting) at Vatican City that must begin no more than 20 days after the death.

The election process is carefully controlled. Blank ballots are prepared and distributed. By lot, the cardinals choose from their group three who collect the ballots of the infirm, three *tellers* (counters of the votes), and three reviewers of the results. After these officials are chosen, each cardinal writes the name of one preference on a ballot. Then each cardinal, in order of seniority, approaches an altar to pledge his integrity of purpose. He then places the folded ballot in a receptacle covered by a plate. Only cardinals under the age of 80 may vote. After all the votes are submitted, the three tellers read each ballot. The last teller reads the results aloud to the cardinals. Two votes are taken every morning and two every afternoon until one man receives two-thirds of the votes, plus one. If no pope has been elected by a two-thirds majority after a certain number of ballots, the cardinals may agree to elect by a simple majority.

After the required majority has been reached, the dean asks the man selected if he accepts his election. If he does, he immediately has full and absolute jurisdiction over the entire church. The dean asks the pope what name he chooses and announces the name to all the cardinals. The cardinals then pay their respects to the new pope.

A large crowd usually gathers in St. Peter's Square to await the outcome of the election. They follow the balloting by watching the smoke that comes from a chimney on the palace roof. All ballots are burned after counting. If the necessary majority is not reached, the ballots are burned in a way that creates black smoke. After the final vote, the ballots are burned in a manner that creates white smoke to signal the election. The oldest cardinal announces the choice to the waiting crowd,

François Lochon, Gamma/Liaison

The election of a pope is announced to the outside world by white smoke emerging from a chimney in Vatican City. The smoke comes from the burning of the ballots after the final vote.

Innocent III was the most powerful of all medieval popes. He influenced the political affairs of much of Europe.

and the pope delivers his first blessing to Rome and to the world. An official coronation is held at a later date.

History

The early papacy. During the early years of Christianity, each local church was independent and led by its own elected bishop. Bishops communicated with one another through letters and personal visits, but they did not have to consult one another on religious questions. Consulting the bishop of Rome was not required, but many churches did so because of Rome's special place in Christian history. As early as the 90's, Pope Saint Clement I (about 92-101) was asserting the Roman See's *primacy* (superior authority) over other churches.

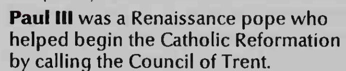
Christians gained freedom of worship in the Roman Empire during the reign of Constantine the Great in the early 300's. The status of the bishop of Rome increased as a result. However, Constantine moved his imperial capital from Rome to Constantinople (now Istanbul, Turkey), and the city was dedicated in 330. After this move, some church leaders in the East came to believe that the See of Constantinople should have equal authority with Rome. Pope Saint Leo I (440-461) argued forcefully for the primacy of the Roman See. He believed that through divine and Biblical authority, the bishop of Rome inherited a "fullness of power" from Peter and was the apostle's legitimate and legal successor.

The early Middle Ages. By the 400's, the Roman Empire in the West was threatened with destruction from repeated invasions by barbarian tribes. These invasions reduced papal authority, which was also weakened by the growth of *heresy* (false doctrine) among Christians in large parts of Africa and Spain.

Pope Saint Gregory I (590-604) defended Italy from barbarian attack. He organized papal lands throughout Italy and Sicily, and collected enough taxes to feed the Roman population and pay Roman soldiers. In the 590's, Gregory made peace with the invading Lombard tribe, which was threatening Rome. Gregory's leadership established the temporal power of the papacy. The conversion of England to Christianity was begun during his reign, and he strengthened the church in Spain, France, and northern Italy.

Hundreds of years of conflict between the Eastern and Western churches led to a historic dispute between Pope Saint Nicholas I (858-867) and Photius, the patriarch of Constantinople. A complete *schism* (split) between the Eastern and Western churches took place in 1054, during the papacy of Pope Saint Leo IX (1049-1054).

Other internal threats to the survival of the papacy emerged during the 800's and 900's. The papacy's reputation and influence declined as Roman nobles tried to control the office through *simony* (selling of church offices), intrigue, and even assassination. Eventually, beginning in the 900's, monks from the Benedictine monastery at Cluny, France, led a reform movement to eliminate simony and the practice of clergy being married. By religious law, clergy were supposed to be *celibate* (unmarried).

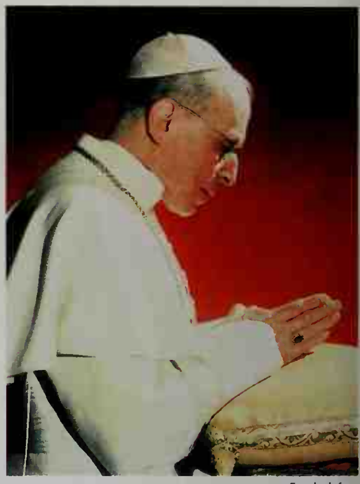


Pope Nicholas II (1059-1061) supported the Cluniac reforms. He restricted the rights of married priests and issued a decree that papal electors must be cardinals, which was directed mainly at simony.

The peak of papal power. Reforms continued under Pope Saint Gregory VII (1073-1085), who issued strongly worded decrees against simony and *lay investiture.* Through lay investiture, secular rulers granted church offices to the clergy of their choice. Lay investiture had given secular leaders considerable influence in church affairs and often allowed unqualified people to receive important religious positions. In a document issued in 1075, Gregory claimed that the pope had the power to depose both temporal and spiritual leaders. He stated that the pontiff held legislative and judicial power over all Christians.

Pope Innocent III (1198-1216) was the most powerful of all medieval popes. He influenced the political affairs of much of Europe and encouraged the establishment of the Franciscan and Dominican religious orders. Innocent was a great administrator and *jurist* (legal expert).

Oil painting on wood (1543) by Titian; Museo Capodimonte, Naples, Italy (SCALA/Art Resource)



Paul III was a Renaissance pope who helped begin the Catholic Reformation by calling the Council of Trent.

Oil painting on canvas (1740's) by Giuseppe Maria Crespi; Pinacoteca Vaticana, Rome (Giraudon/Art Resource)

Benedict XIV was admired for his high moral character and his support of religious and secular education.

Farabolafoto

Pius XII was one of the most active popes in history, updating and revising many church practices and customs.

He helped make it common practice to refer to the pope by the more exalted title "Vicar of Christ," instead of such older titles as "Vicar of St. Peter."

The papal claim to primacy was expressed dramatically by Pope Boniface VIII (1294-1303) in a *bull* (papal decree) of 1302 called *Unam sanctam.* In the bull, Boniface claimed that every human being's salvation depended upon submission to the authority of the pope. Boniface saw the pope as Christ on earth, the exclusive instrument of salvation.

The troubles of the papacy. During much of his reign, Boniface VIII came into conflict with the French king, Philip IV. In 1303, soldiers led by a French official took the pope prisoner at his family home at Anagni, Italy. Although the pope was released after three days, the episode symbolized the end of the medieval attempts to broaden papal power over Europe's secular rulers. From 1309 to 1377, the popes resided at Avignon, in what is now France. This period, sometimes called the *Babylonian Captivity,* introduced a time of turmoil in the papacy known as the *Great Schism.*

The Great Schism lasted from 1378 to 1417. During this time, candidates from Avignon and Rome both claimed to be the rightful pope. In 1409, the Council of Pisa tried to untangle the dispute but instead created a third claim to the office. Finally, the Council of Constance resolved the conflict in 1417. One man *abdicated* (resigned) and the two other candidates were deposed. A new pope, Martin V (1417-1431), was elected in their place as the single legitimate pontiff.

Renaissance and Reformation. The Renaissance was a European cultural movement that began in Italy during the early 1300's and spread throughout western Europe over the next 200 years. It stimulated perhaps the most powerful social force of modern times, the spirit of nationalism. This spirit showed itself in national antipapal attitudes in France and England. Taking advantage of such attitudes, the French and English kings forced the papacy to grant to royalty sizable shares of church taxes and property. The slow loss of church funds resulted in a loss of papal power, which was transferred to secular rulers. National churches in England and France developed as rivals to the international church ruled by the pope.

Many Renaissance popes were sophisticated Italian princes who came from prominent Italian families like the Borgias and the Medicis. Many were educated as diplomats, secular scholars, or patrons of the arts, but not as religious leaders.

A number of Renaissance popes were notable for their questionable moral character. Popes from the Italian nobility often combined worldly attention to the arts with promoting their powerful families. Pope Sixtus IV (1471-1484) was a patron of the arts and scholarship. He also made three of his nephews cardinals. One of them became Pope Julius II (1503-1513). Julius II appeared interested in reform. He was a shrewd administrator and supported the work of the famous artists Raphael and Michelangelo. However, Julius was more concerned with political and military affairs than with the religious life of the church. He achieved no significant reform and did nothing to improve the papacy's moral image.

Toward the end of the Renaissance, several popes did attempt internal reforms. By this time the church was facing the threat of the Protestant Reformation, a movement that had swept through large parts of Europe. The Protestants did not accept the authority of the pope, and they broke away from the Catholic Church. A Catholic renewal movement known as the Counter Reformation, or Catholic Reformation, developed in the 1500's and 1600's. Pope Paul III (1534-1549) called the Council of Trent, which met periodically from 1545 to 1563. At the council, bishops struggled to reform church practices as well as to define Catholic belief. Paul III also formally approved the Society of Jesus (known as the Jesuits), a religious order established in 1534. The Jesuits became an influential group whose members pledged their loyalty directly to the pope.

Church efforts at reform extended through the Thirty Years' War (1618-1648) in Europe. According to the

John Paul II, who was born in Poland, in 1978 became the first non-Italian pope since Adrian VI of the Netherlands.

Peace of Westphalia that ended the war, a ruler's religion would determine the religion of the ruled area. This principle, which reflected the nationalism that was dominating Europe, further reduced the influence of the papacy, especially in Protestant Germany. By the mid-1600's, rulers of the new nation-states were viewing their power in absolute terms and challenging any papal claims to that power.

The 1700's and 1800's. During the 1700's, the papacy came under attack from several sides. A movement within the German church called *Febronianism* tried to limit claims to papal power. A similar doctrine, called *Josephism,* was put into practice by the Holy Roman emperor. In France, the *Gallicanism* movement had similar goals. At the same time, Voltaire and other French thinkers called the *philosophes* were strongly opposed to Christian churches. Their thinking influenced popular opinion against organized religion and the Roman Catholic Church in particular.

Pope Benedict XIV (1740-1758) was probably the most admired pontiff of the 1700's. He gained respect from both Protestants and Catholics for his enlightened reign. Benedict was a skillful administrator and tried to strengthen the moral influence of the papacy. He encouraged education and founded academies for the study of Christian and Roman history.

During much of the 1800's, the popes joined with conservative political forces who were ruling Europe. These forces supported the church because of its long tradition as a stabilizing social influence. Its conservative alliances put the papacy into further opposition with European liberals, who were often antipapal. The liberals claimed that the church was blocking scientific and political progress.

Pope Pius IX (1846-1878) ruled longer than any pope in history. Pius originally had been a liberal who favored unification of territories like the Italian states. But continued threats to papal power from Italian nationalists turned him into a strong conservative. In his *Syllabus of Errors* (1864), he condemned what he believed were errors of modern thought, including liberalism, rationalism, communism, and socialism. By 1870, all of the land that had once made up the Papal States was part of the independent kingdom of Italy. The pope's territory was reduced to the Vatican and Lateran palaces and the papal villa at Castel Gandolfo. Pius shut himself inside the Vatican and considered himself a prisoner. His successors followed the same policy for nearly 60 years, until the Lateran Treaty created the independent country of Vatican City in 1929.

As the political power of the popes decreased, their display of authority within the church grew stronger. The papacy presented itself as guardian of a clearly defined system of beliefs, opposed to Protestantism and the main currents of modern thought.

The papacy today. The popes of the 1900's became extremely active teaching church doctrines and morals. Their encyclicals (pastoral letters) influenced Catholic thinking on a wide range of issues. These issues included social justice, family life, the value of the sciences, and the legitimacy of other faiths. At the same time Catholic thought came into greater harmony with major intellectual developments, especially in such fields as philosophy, the natural sciences, history, and Biblical studies.

John XXIII (1958-1963) became one of the most popular of all modern popes. He called Vatican Council II to provide a renewal and updating of Catholic religious life and doctrine. The council opened in 1962 and ended in 1965, after John's death. One of the council's most challenging themes was *collegiality,* the idea that authority in the church is shared by the pope and a consensus of bishops and other clergy. John's successor, Paul VI (1963-1978), presided over the final years of the council. He withdrew controversial questions of celibacy and birth control from the council and reserved action on these topics to himself.

In 1978, John Paul II was elected the first non-Italian pope since Adrian VI (1522-1523) of the Netherlands. John Paul established himself as one of the most active

Antipopes in _italics._
Sources: _Catholic Almanac_ and _New Catholic Encyclopedia._
*Has a biography in _World Book._

†An error in numbering occurred when another St. Felix was mistakenly included as a pope in some earlier lists. Popes St. Felix III and IV and antipope Felix V should each be moved up.
‡In 1961, the church dropped Stephen II, who died in 752, from the list of popes. The numbers of the others named Stephen were moved up.

popes in church history. He has traveled more and been seen by more people around the world than any previous pontiff.

Willingness to deal with important social and political issues has helped increase the prestige of the papacy. But confronting these issues has also created tensions between liberals and conservatives within the church. Some of these tensions center on sensitive social topics, such as abortion, women's rights, and divorce. Others concern relations between the Holy See and members of the Roman Catholic Church as well as relations with other Christian churches and non-Christian religions.

Pope, Alexander (1688-1744), was the greatest English poet of the early 1700's. His brilliant verse satires ridiculed many kinds of human follies. Pope's biting wit made him one of the most feared writers in England.

Pope wrote in heroic couplets, with two rhymed lines of 10 syllables each. His polished, concise verse shows a keen feeling for sound and rhythm. Pope has become one of the most quotable poets. He wrote many famous lines, including a couplet from *An Essay on Criticism* that expressed his literary creed:

> True wit is Nature to advantage dress'd,
> What oft was thought, but ne'er so well express'd.

Pope's career can be divided into three periods. During the first period, from about 1709 to 1715, he wrote *An Essay on Criticism* (1711). This witty poem about criticism and writing made him famous at the age of 23. It includes two famous lines: "A little learning is a dangerous thing" and "To err is human, to forgive divine." Pope's *The Rape of the Lock* (1712, 1714) is the most famous mock-epic poem in the English language. In the poem, Pope satirizes the vanities of fashionable people. *The Rape of the Lock* tells about a pretty young woman whose lock of hair is snipped off by a suitor at a party. A "battle of the sexes" follows, and Pope states his moral:

> Oh! if to dance all night, and dress all day
> Charm'd the smallpox, or chased old age away,
> Who would not scorn what housewife's cares produce,
> Or who would learn one earthly thing of use?

During his second period, from 1715 to 1726, Pope devoted himself to translating and editing. His translation of the Greek epic poem the *Iliad* (1715-1720) made him financially independent. With the profits, Pope bought a villa at Twickenham in 1719, and he spent most of his remaining years there writing.

During his last period, Pope wrote his most serious satires. They express his belief in the value of common sense, a moral life, friendship, poetry, and good taste. *An Essay on Man* (1733-1734) is a long, ironic, philosophical poem. It includes the well-known line "Hope springs eternal in the human breast." Pope's four *Moral Essays* (1731-1735) are satirical poems in the form of letters. One of these poems lightly exposes the follies that Pope saw in women, and another ridicules people who misuse wealth.

Imitations of Horace (1733-1738) is patterned after the verse *epistles* (letters) and satires of the Roman poet Horace. The poem is prefaced by "An Epistle to Dr. Arbuthnot" (1735). In this pleasant satire, Pope created a favorable picture of the poet as a man who is independent, good, and a lover of truth. In addition, the poem attacks Pope's enemies, especially the author Joseph Addison.

Pope's last major work was *The Dunciad* (1728-1743), an attack on dunces. The poem ridicules dull writers, biased critics, overly scholarly professors, and stupid scientists. Pope particularly ridiculed the critic Lewis Theobald and the writer Colley Cibber.

Pope was born in London. At age 12, he suffered a tubercular spinal infection. As a result, he grew to an adult height of only 4 feet 6 inches (137 centimeters) and developed a hunchback. Pope was extremely sensitive about his appearance. Gary A. Stringer

Poplar is any one of a group of fast-growing trees that are found throughout the Northern Hemisphere. Aspens and cottonwoods are poplars. About 10 of the 35 species in the group are native to North America. These trees have pointed leaves with wavy, toothed edges. Many kinds of poplars have such flat leafstalks that even a slight breeze will cause the leaves to flutter. Early in the spring, before the leaves appear, small greenish flowers form in drooping clusters called *catkins.* Tiny seeds are hidden in fluffy, cottony hairs that make it easy for the wind to carry them through the air.

Poplars grow best in moist places. They grow easily

WORLD BOOK illustration by John D. Dawson

The balsam poplar grows in Canada and the Northern United States. Its buds and young leaves have a fragrance of balsam.

from *cuttings* (cut twigs). People often plant poplars for shade trees because they grow fast. But poplars do not live long. Also, their roots tend to clog underground drainpipes and sewers. For this reason, it is illegal in some cities to plant poplars along streets.

Poplar wood is whitish or light brown. The wood is also soft, light, and weak. Manufacturers use it to make boxes and crates. Papermakers use it for paper pulp and to make *excelsior* (wood shavings used for stuffing furniture and for packing breakable objects).

Balsam poplar, or *tacamahac,* grows across Canada. It lives as far north as trees will grow and south to the Northern United States. The sticky buds and young leaves have an odor of balsam. Honey bees use the fragrant gummy substance to waterproof their hives. *Balm of Gilead,* a cultivated variety, has heart-shaped leaves.

The *white poplar* has leaves that are silvery white beneath and have three or five lobes like a maple leaf. The bark on the branches is white. The *Lombardy poplar* is tall and narrow and has diamond-shaped leaves. Its branches point upward. The white and Lombardy poplars are native to Europe and have been introduced into the United States. People often planted these poplars in rows in formal gardens and for roadside landscaping. But their popularity as landscape trees has declined because they are easily damaged by insects, wind, and disease. These trees do not produce seeds.

The *Carolina poplar* is a hybrid derived from the native eastern cottonwood and the black poplar from Europe. This type has triangular leaves. It can endure city smoke and dust and often is seen growing in large cities. All Carolina poplar trees are male and do not produce the cottony seeds found in other varieties.

Richard C. Schlesinger

Scientific classification. Poplar trees belong to the willow family, Salicaceae. Balsam poplar is *Populus balsamifera;* white poplar is *P. alba,* Lombardy poplar is *P. nigra,* var. *italica.* Carolina poplar is *Populus canadensis.*

Popocatépetl, *PAW paw kah TEH PEHT uhl* or *POH puh KAT uh PEHT uhl,* is a volcanic mountain that lies about 45 miles (72 kilometers) southeast of Mexico City (see **Mexico** [terrain map]). Popocatépetl is one of North America's highest mountains, rising 17,887 feet (5,452 meters) above sea level. Mount McKinley, highest mountain on the continent, is only 2,433 feet (742 meters) taller than Popocatépetl. The summit of Popocatépetl is covered with snow. Evergreen forests grow on its lower slopes.

Since at least the 1300's, Popocatépetl has erupted from time to time, spewing out gas, steam, smoke, and ash. Because of these periodic eruptions, the Aztec who lived nearby named the volcano Popocatépetl, which means *smoking mountain.* Popocatépetl is often called simply "Popo."

During the 1520's, soldiers in the army of Spanish conqueror Hernando Cortés entered Popocatépetl's crater to obtain sulfur to make gunpowder. Some mining for sulfur has taken place since then. Popocatépetl has become a popular mountain-climbing site.

Popper, Karl Raimund (1902-1994), was an Austrian-born philosopher whose central concern was analyzing the nature of science. In his major work, *The Logic of Scientific Discovery* (1935), Popper argued that science does not begin with the gathering of evidence through observation of the world. It begins with the formulation of scientific *hypotheses* (laws or theories to be tested). The formulation of hypotheses is a creative act that precedes, shapes, and makes possible the gathering of any evidence. According to Popper, evidence is gathered only to test some already formulated hypothesis.

In his popular work *The Open Society and Its Enemies* (1945), Popper argued that the admired philosophers Plato, G. W. F. Hegel, and Karl Marx were enemies of freedom because they laid the intellectual foundations for the totalitarian state.

Popper was born in Vienna and taught there until 1937 when he left the country because of the rise of the Nazis. He taught at the London School of Economics and Political Science from 1949 to 1969. Queen Elizabeth II knighted him in 1965, making him Sir Karl Popper.

Ivan Soll

Poppy is the common name for several related groups of flowers. The most important member is the white, pink, red, or purple opium poppy of China, India, and Iran. It has been raised in the Orient since ancient times.

The flowers of poppies are admired for their delicate beauty and gracefulness. Breeders have produced many variations in the size and form of the blossom. Most kinds are hardy and easy to cultivate. The tiny seeds have no narcotic properties, and they are sold for bird food. They also yield an oil used in preparing some foods. The oil cake remaining is a valuable cattle food. Poppy seeds are also used as flavoring. Poppy seeds may be sprinkled on bread and rolls, or used in filling for cakes.

The common corn poppy grows wild in the grainfields and grassy meadows of Europe. Many varieties of the corn poppy, including the *Shirley poppy,* are grown from seed in flower gardens. The *Iceland poppy* grows as far south as Colorado. Its long-lasting flowers are various shades of white, orange, yellow, rose-pink, and scarlet. The California poppy, or "cup of gold," grows wild in the "Golden State." The most showy poppy is the large-flowered Oriental poppy. This poppy's red, orange, white, or salmon blossoms often have blackish-purple centers.

Many poppies are annual plants that can be grown from seed. However, the Oriental poppy is a perennial, and this plant is best transplanted by root sections. The

poppy is one of the flowers of the month of August.

Opium comes from the young capsules of the opium poppy where the seeds develop. To obtain it, workers scratch the capsules late in the day. The milky juice that seeps out solidifies overnight, and is collected the next day. It takes 120,000 capsules to yield 25 to 40 pounds (11 to 18 kilograms) of opium.

Scientific classification. The poppy family is Papaveraceae. The opium poppy is *Papaver somniferum;* the corn poppy, *P. rhoeas;* the Iceland poppy, *P. nudicaule;* the Oriental poppy, *P. orientale.* The California poppy is *Eschscholtzia californica.*

Popular music is music created as a commercial product. It is usually distinguished from classical music and from folk music. Classical music is written chiefly for concerts, operas, and ballets. Folk music is the traditional music of a particular group or community of people, such as an occupational, ethnic, or regional group. Folk music is usually learned by listening to another person rather than by reading music.

There are many different styles of popular music in the United States, including bluegrass, blues, country, gospel, jazz, musical comedy, rap, reggae, and rock. In some cases, the categories of popular, folk, and classical music overlap. For example, jazz and country music evolved out of folk traditions. Some styles, such as blues and bluegrass, exist both as popular music and as folk music. Such classical composers as Leonard Bernstein and Louis Moreau Gottschalk have written pieces in the style of popular music.

Although much popular music expresses sentiments of love, other popular songs serve as a vehicle for social commentary. Popular music is frequently thought to have meaning only for the time in which it was created. However, many popular songs have endured for decades.

Popular music before recording

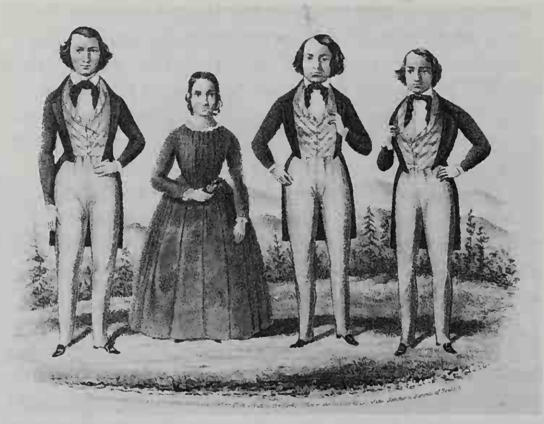
The colonial period (1607-1776). Before the Revolutionary War in America (1775-1783), virtually the only music published in the American Colonies was religious music. Much of it consisted of settings of hymns and psalms by William Billings and other composers. People sang these pieces in church, at gatherings in their homes, and in singing societies. Billings and other composers also ran singing schools, partly to build a market for their music.

Secular (nonreligious) music also flourished in the colonies, but much of it was passed orally from person to person, without being published. Colonists sang folk and popular songs from Great Britain and songs written by Americans in the British style. Many songs were sold on *broadsides*—large sheets of paper with lyrics printed on one side. The broadsides provided no music, only words, with directions that they were to be sung to a familiar tune.

Black slaves often performed as musicians at dances and other social functions. They played instruments from Africa, including forerunners of the banjo. They also played the violin and other European instruments.

Revolutionary War to 1840. Extensive publication of nonreligious music began in the United States in the 1790's. At that time, most American music publishing companies were located in New York City, Boston, Philadelphia, and Baltimore. These companies published sheet music, mostly for solo voice with piano accompaniment. In addition, collections of songs and instruction books for such instruments as flute, fife, and violin began to appear. Most of these volumes contained dances, marches, and other popular melodies of the time. Also common were small books called *songsters.* Like broadsides, most songsters included only the words to popular melodies.

During this period, American popular music continued to be heavily influenced by music from abroad. An Englishman, Henry Bishop, composed or arranged the music to "Home, Sweet Home," perhaps the most popular song of the 1800's. The text was written by American poet John Howard Payne. The Irish poet Thomas Moore wrote new lyrics for traditional tunes in *Irish Melodies* (1808-1834), which became extremely popular in the United States. " 'Tis the Last Rose of Summer" and "Believe Me If All Those Endearing Young Charms" were among the songs in Moore's collection to become widely popular.



1840's to the Civil War. During the mid-1800's, American popular music began to develop its own identity. *Minstrel shows* became a popular form of entertainment. In minstrel shows, white entertainers wore blackface makeup to impersonate blacks. They performed songs, skits, dances, and comedy routines that reflected their conceptions of black life and music.

Minstrel shows were performed in a spirit of parody and did not present authentic black music. However, they did bring some basic elements of black music to large audiences for the first time. The instruments minstrels played—including banjos, fiddles, tambourines, and bones—were characteristic of slave music. Minstrel performers also incorporated the technique of banjo playing used by black musicians. "Old Dan Tucker" (1843) and "Dixie" (1859) by Daniel D. Emmett are two songs that were first performed on the minstrel stage.

The most important American songwriter of the mid-1800's was Stephen Foster, who rose to fame writing songs for minstrel shows. Foster was the first American to make his living as a songwriter. Many of his compositions, such as "Oh! Susanna", "Camptown Races" (1850), and "Old Folks at Home" (1851, also called "Swanee River"), are still popular.

Also rising to prominence in the 1840's was the Hutchinson Family—a singing group made up of three brothers and a sister from New Hampshire. The Hutchinsons were among the first American performers to use popular music as a vehicle for social commentary. For example, some of their songs protested slavery or urged an end to the use of alcohol.

The Civil War (1861-1865) was of great importance to American popular music. People often expressed in song the strong feelings aroused by the war. As a result, there was a tremendous increase in composition and publishing. Such songs as "Battle Hymn of the Republic" (1862) and "The Battle Cry of Freedom" (1862) reflected Northern attitudes. Southerners, meanwhile, expressed the sentiments of the Confederacy in "Dixie" and "The Bonnie Blue Flag" (1861).

New Hampshire Historical Society

The Hutchinson Family in the 1840's were among the first performers to use popular music for social commentary.

The Civil War also had an impact on music in many other ways. It provided musical training for soldiers who played in military bands. In addition, the war brought people from different parts of the country together. These contacts enabled people to learn about one another's musical styles, instruments, and songs. Of particular importance was the exposure Northerners gained to authentic black music, notably the religious songs called *spirituals.* Up to this time, most Northerners' conception of black music had come only from minstrel shows.

The end of slavery in the United States after the Civil War enabled a greater number of blacks to become professional musicians and songwriters. Black groups who specialized in singing spirituals became popular in the late 1800's. In addition, all-black minstrel troupes were formed during this period.

Vaudeville and musical comedy. During the late 1800's, a new type of variety show called *vaudeville* replaced the minstrel show as the dominant form of stage entertainment. Like minstrel shows, vaudeville consisted of songs, dances, comic skits, and other acts. The two differed, however, in that vaudeville reflected Northern white influences rather than black Southern culture. Vaudeville was at the height of its popularity from the 1880's to the 1930's.

By the end of the 1800's, music publishing centered in an area around 28th Street in New York City that came to be known as Tin Pan Alley. The area got its name from the noise of the cheap pianos in song publishers' offices. Musicians sometimes called these pianos "tin pans." New York City also became the hub of *musical comedy.* A musical comedy, or *musical,* is a type of play that tells a story through a combination of spoken dialogue, songs, and dances. Many of the songs published by Tin Pan Alley originated in musicals. Tin Pan Alley controlled the publication of popular music throughout the early 1900's, and musicals remained an important means for introducing new songs to the public. Musical comedy composers who wrote many popular songs during this period include Irving Berlin, George Gershwin, Jerome Kern, Cole Porter, and Fats Waller.

Ragtime, jazz, and blues. With the changes brought about by the Civil War, the South became fertile ground for new musical styles during the late 1800's. Instruments rarely used by slaves, such as pianos, guitars, and brass instruments, became central to the new styles of black music that developed and flourished during this period. Noisy bars became the usual setting for dancing. The loud piano replaced the fiddle and banjo as the favorite means of providing dance music. *Ragtime,* a style of music often played on the piano, developed in the 1890's in the Midwest. Ragtime was *syncopated* music. That is, it accented the weak beats rather than the strong beats. Music historians trace the roots of ragtime to plantation dance music such as the *cakewalk,* to minstrel shows, and to music for black stage shows. Early in ragtime's development, Scott Joplin and other composers began writing formal compositions in the ragtime style. Ragtime soon became popular throughout the United States and flourished in the first two decades of the 1900's.

Another new style of music called *jazz* developed in New Orleans around 1900. Jazz also was partially rooted

Roy Acuff and the Smoky Mountain Boys; Culver

Country music spread nationally from the South through performances by such stars as Roy Acuff, *playing the fiddle.*

Ellington and his orchestra about 1931; UPI/Bettmann

Duke Ellington, *center,* was an orchestra leader and composer who helped make jazz a major form of popular music.

in black dance music, as well as in the brass band music played in New Orleans during funeral processions and parades.

Still another new style called the *blues* became popular in the early 1900's. The blues probably developed from work songs and the calls known as *field hollers* that plantation workers used as a form of communication in the fields.

The recording era

Sound recording, invented in 1877, became an important way to distribute popular music in the early 1900's. In the 1920's, records surpassed sheet music as the primary means through which popular music was sold. With this shift, songwriters and publishers were no longer the dominant force in popular music. Instead, music began to be dominated by performers and record companies. The rise of sound recording also changed the ways in which people enjoyed popular music. Instead of gathering around the piano at home to sing the latest songs themselves, people played recordings of other people singing.

Record companies discovered and exploited new markets during the early 1900's. In the process, they helped popularize several types of music. The first recordings of jazz were made in 1917 by a group of white musicians called the Original Dixieland Jass Band. The first blues recordings were made in 1920. On some early blues records, professional blues singers such as Bessie Smith and Ma Rainey performed with some important jazz musicians. Other blues musicians, such as guitarists Charley Patton and Robert Johnson, played a more emotional style of music often called *Delta blues* because it originated in the Mississippi Delta region.

The rise of country music. The recording industry also helped spread a kind of music called *country music.* Country music combined elements of popular song, British folk music, American blues, and religious music. It was first recorded in 1922. The recordings were marketed as *hillbilly music,* partly because of a popular band called the Hill Billies.

Radio exposed people to different kinds of popular music in the 1920's and 1930's. Live radio shows such as "The Grand Ole Opry," broadcast from Nashville, Tenn., brought country music to large, new audiences.

Other new styles of popular music continued to emerge from the 1920's to the 1940's. A new type of jazz called *swing* developed in the 1930's. Big bands dominated the swing era and helped advance the careers of such musicians as Count Basie, Duke Ellington, and Benny Goodman. Musicians combined country with jazz in the 1930's to produce what later became known as *Western swing.* Country string band music gave birth to a new style called *bluegrass,* pioneered by Bill Monroe and his band, the Blue Grass Boys beginning in 1939.

The blues expanded as many blues musicians left the rural South and moved to Chicago and other Northern cities. There, in the late 1940's, they developed a style of music called *rhythm and blues.* Unlike traditional blues, rhythm and blues used electrically amplified instruments rather than *acoustic* (nonelectric) guitars.

Rock 'n' roll. Popular music underwent a major revolution in the 1950's, as young musicians combined elements of rhythm and blues, country music, and popular songs to create a new style called *rock 'n' roll* (also spelled *rock and roll*). Elvis Presley was the most significant early rock 'n' roll artist. A wave of rock groups from England became extremely popular in the United States, beginning in 1963. The Beatles were the most influential of these groups, who were inspired by American rhythm and blues and early rock 'n' roll.

The folk music revival. In the late 1950's, traditional white American folk music gained new popularity. Young, urban, college-educated performers such as the Kingston Trio had hits with the Appalachian ballad "Tom Dooley" (1958) and other folk songs. Other performers in this folk music revival were inspired by Woody Guthrie. Guthrie wrote songs that used traditional folk melodies and styles. These singer-songwriters began composing their own songs. These songs frequently had the theme of social protest. Bob Dylan, whose songs include "Blowin' in the Wind" (1962) and "The Times They Are A-Changin' " (1963), was the most important writer of this movement.

Soul music became the most popular form of black music in the 1960's. Growing out of rhythm and blues, and influenced by black gospel music, soul gained popularity with white and black audiences alike. Aretha Franklin and James Brown were important soul artists.

New forms of rock. Mainstream popular music in the 1970's was dominated by a dance-oriented rock style called *disco.* The *punk rock* and *new wave* movements popular in the mid- and late 1970's began partly as a backlash against the technical, impersonal sounds of disco.

Country rock gained more widespread acceptance during the 1970's. Such artists as the Byrds, the Eagles, Emmylou Harris, Willie Nelson, Dolly Parton, and Linda Ronstadt combined elements of rock and country in their music.

The rise of rap as the dominant form of black popular music began in the 1980's. Growing out of black street culture in New York City, rap consists of words recited over a strong rhythm track. Many rap groups use the form to comment on such social problems as racism and poverty. Some rap artists have generated controversy because their lyrics deal graphically with sex and violence.

New technologies for the spread of popular music also arose in the 1980's. Short films called *music videos* became a new means for promoting songs and artists. Some artists, such as Madonna and the Eurythmics, owe much of their success to the popularity of their videos. Compact discs (CD's) and cassette tapes overtook phonograph records as the most popular media for sound recording in the late 1980's. Paul F. Wells

Popular sovereignty, also called *squatter sovereignty,* was the doctrine that the people of a territory, rather than the United States Congress, should decide whether to permit slavery in the territory before it became a state. The theory of popular sovereignty developed during the controversy over slavery that is part of the history of the early United States.

The North, as a whole, opposed extension of slavery into any of the land acquired from Mexico after the Mexican War ended in 1848. The South almost unanimously favored expansion of slavery into this new territory. Many people on both sides found the theory of popular sovereignty a useful solution to the disagreement that relieved Congress of a difficult problem.

Lewis Cass, a Democratic senator from Michigan, probably originated the theory of popular sovereignty. But Stephen A. Douglas, a Democratic senator from Illinois, was the first person to use the term *popular sovereignty* and the idea's most prominent advocate.

The Kansas-Nebraska Act of 1854 permitted the people of the Kansas and Nebraska territories to decide for or against slavery within their respective borders. The authors of the law took for granted that Nebraska would vote free, and Kansas, slave. But antislavery advocates sent many free-state settlers into Kansas, while many proslavery residents of Missouri crossed into Kansas, sometimes to settle, but often only to vote. The bloodshed that resulted showed that the principle of popular sovereignty would not work. Soon after the American Civil War ended in 1865, slavery was abolished and the theory of popular sovereignty lost its significance.

Robert F. Dalzell, Jr.

See also **Douglas, Stephen Arnold; Kansas-Nebraska Act.**

Population of a country or other area is the total number of people who live in it. Populations change as a result of migration and a process called *natural increase.* Natural increase is the difference between births and deaths. Most countries have more births than deaths, and so their population increases, unless a net loss results from migration.

World population

The world's population rose to about 6,228,635,000 by 2002. The number of people is increasing at an annual rate of about 1.2 percent. Scholars estimate that the world's population totaled about 550 million in 1650. By 1850, the population had doubled to about 1,100 million. Since 1850, the world's population has increased nearly sixfold. See **World** (Population; diagram).

European populations in Europe and overseas increased rapidly in the 1700's as death rates dropped. But declines in birth rates reduced population growth and eventually led to a decrease in some countries. During the 1980's, European countries with decreasing populations included Hungary, Ireland, Portugal, and West Germany.

In most of Asia, Africa, and Latin America, death rates declined rapidly during the mid-1900's. Longer life spans were brought about by the reduction of famines and epidemics, by improved water supplies and sewage disposal, and by better medical care.

The populations of continents show the effects of differing rates of both migration and natural increase. The past 300 years have been a period of several great migrations, including that of Europeans to the Americas and some Pacific areas.

Asia is the most populous continent, with about three-

World population and yearly growth

Major area	Population	Yearly growth
World	6,228,635,000	1.2%
Africa	831,437,000	2.4
Asia	3,799,971,000	1.2
Australia	19,231,000	0.9
Europe	701,188,000	−0.1
North America	495,369,000	0.7
Pacific Islands (including New Zealand)	15,311,000	1.2

fifths of the world's population. The two countries with the largest populations are in Asia. They are China, which had nearly 1 $\frac{1}{3}$ billion people in 2000, and India, which had more than 1 billion. The two next largest countries are the United States, with about 285 million people, and Indonesia, with about 215 million.

Urban and rural population. Migration from rural areas to cities grew with industrialization in Western countries and Japan. Today, it is occurring in most countries, even in those that remain predominantly agricultural. In 1800, only about 5 percent of the people of the United States lived in places with a population of 2,500 or more. Today, about 75 percent live in places of that size or larger. In 1800, about 20 percent of the population of England lived in cities. Today, about 95 percent live in cities.

Census. Most governments conduct *censuses* (regular counts of the population) to learn the numbers, the places of residence, and the characteristics of their peoples. Most countries in the world have taken at least one census in the last 10 years. The United States government has taken a census of the American population every 10 years since 1790.

Governments also collect information on birth and death rates, called *vital statistics*. The study of the size, distribution, and characteristics of populations, and of changes in population, is called *demography*. The United Nations helps countries improve their demographic information.

Age. A population growing rapidly because of a high birth rate usually has a high proportion of children. A slowly growing population usually has a low proportion of children. Current estimates for the population of the world indicate that about 32 percent of the people are below 15 years of age. About 62 percent of the people are between the ages of 15 and 64, and fewer than 6 percent are over 64 years of age. In the United States, 21 percent of the people are less than 15 years old, 66 percent between 15 and 64, and 13 percent over 64. In Kenya and other countries with high birth rates, about half the people are below 15 years of age.

Statistics on the proportions of various age groups help society prepare for more schoolchildren, workers, or aged people. The *dependency ratio* is a comparison of the number of children and elderly people with the number of people in the main working ages. This ratio is high if a large proportion of the population are dependents. Nations with a rapidly growing population have a high dependency ratio. The support of dependents places a burden on the workers of such countries, and many children and older adults may try to find work.

United States population

In the United States, the first federal census in 1790 determined that about 4 million people lived in the country. By 2000, the United States population had increased to about 280 million. The rate of growth was highest from 1790 to 1860, when it was about 3.5 percent a year. By the 1930's, the rate had decreased to 0.7 percent a year.

Another period of rapid growth, called the *baby boom,* occurred in the United States from 1946 to 1964. The growth rate reached a high of 1.8 percent during this period. Since 1964, the rate has again slowed. Today, the growth rate is about 1 percent a year. About one-third of this growth is due to immigration rather than natural increase.

The growth of the various regions of the United States is influenced greatly by migrations within the country. Since 1970, the West has grown most rapidly and the Northeast region least rapidly. Mild climates and economic expansion attracted many people to the South and West.

Men outnumbered women throughout most of the history of the United States because men were more numerous than women among immigrants. But death rates at most ages are higher for men than for women. Thus, as immigration declined, the proportion of women increased. Since 1950, there have been more women than men in the United States. Women will likely remain in the majority despite recent high levels of immigration because today's immigrants include many family groups and single women.

The U.S. population is made up of people of many nationalities and ethnic groups. For statistical purposes, the main groups are: (1) whites who are not Hispanics (about 69 percent of the people); (2) Hispanics of any race (about 13 percent); (3) blacks who are not Hispanics (about 12 percent); (4) Asians and Pacific Islanders (about 4 percent); and (5) Aleuts, Inuit (also called Eskimos), and American Indians who are not Hispanics (less than 1 percent).

The future growth of the population depends on many factors, and it is not possible to know exactly what will happen. The U.S. Census Bureau expects that the rate of population growth in the United States will remain low. Nevertheless, the total population may reach 300 million in about the year 2006.

The population explosion

The world's population passed 5 billion in 1987, then passed 6 billion in 2000. The population is increasing by approximately 1.2 percent each year. If this rate of growth continues, the population will reach about 9 billion by the year 2035. This rapid increase has been called the *population explosion.*

Causes. For thousands of years, birth rates were high. However, the population increased slowly and some-

times declined because death rates also were high. Then, during the 1700's and 1800's, advances in agriculture, communication, and transportation improved living conditions in parts of the world and reduced the occurrence of many diseases. As a result, the death rate began to drop, and the population grew rapidly.

In the industrial countries of Europe and North America, many people flocked to the cities and took jobs in factories. In cities and in many rural areas, it was difficult to support a large family. People began to see reasons for having smaller families. As a result, birth rates in these countries began to fall. In the agricultural countries of Africa, Asia, and Latin America, declines in death rates did not occur until the mid-1900's. Then death rates plunged quickly without corresponding declines in birth rates. As a result, the population of low-income nations and of the world increased rapidly.

Effects. Many scientists, economists, and other experts fear that food production cannot keep pace with the population for long. They believe the world already is or will soon become *overpopulated*—that is, it will have more people than it can support at an acceptable standard of living. This theory was put forth by the British economist Thomas Robert Malthus in the late 1700's. Malthus stated that population tends to increase beyond the limit of the earth's ability to support it. He predicted that famine, war, and other disasters would become common unless people cut the growth rate.

Many people dispute Malthus's views. They point out that since Malthus made his gloomy forecast, world population has grown by more than 4 billion. More people are living longer and healthier lives than ever before. Many experts believe it is technologically possible to increase world food production by more than 1.7 percent yearly and thus to keep ahead of population growth. During the 1960's, for example, improved farming methods and new high-yield crop varieties helped many poor countries increase their food production by about 25 percent. This effort proved so successful that it has been called the *Green Revolution.* Some people believe that the problem is not too many people, as Malthus claimed there were, but too much inequality. They think that starvation and poverty could be overcome with a more equal distribution of existing resources. Many people have more than enough to eat, but many others go hungry.

Population control. Many experts worry that people in rich and poor countries alike consume too much, destroy forests and soil, pollute the environment, and damage prospects for human survival on earth. They believe disastrous shortages of food and other necessities can be avoided only by halting population growth. They urge that the birth rate be reduced to replacement level, an average of about 2.1 children per woman, so that only enough people are born to replace those who die. The resulting condition is called *zero population growth* or ZPG. In the United States and much of Europe, fertility is below replacement level. But in many of the world's poorer countries, women have an average of as many as 7 or 8 children.

The governments of many countries have promoted birth control programs in efforts to reduce the birth rate. China, for example, has persuaded millions of couples to have only one child. In many other countries, birth rates have declined more slowly and are still far above replacement level.

The decisions that women and men make about having children are influenced by many other factors besides government policies. These factors include their social and economic circumstances, their education, their need to have someone care for them in their old age, their feelings about the future, and their access to information and medical care. As a result, future social and economic changes will have important effects on birth rates and population growth. Karl Taeuber

Populism was an American political movement that attained its greatest strength during the 1890's. The Populists supported an increase in the money supply, greater government regulation of business, and other changes they believed would help farmers and laborers. In addition, they called for many reforms to increase the political power of voters. Many Populist leaders were colorful figures who stirred up the people with rousing speeches. The word *populist* also describes political policies like those of the Populists, especially policies that favor the common people.

Origins. Populism began among the farmers of the Midwest, South, and West. During the 1870's and 1880's, these farmers suffered from a combination of falling crop prices and rising operating costs. Railroad freight rates and interest rates charged by lenders caused much resentment among farmers. To address these problems, groups of farmers joined to form *farmers' alliances.*

The farmers' alliances called for the government to put more money into circulation, either by printing more paper money or by coining unlimited amounts of silver. Such a coinage policy was called *free silver.* The farmers believed an increase in the money supply would help them get higher prices for their crops. The farmers also wanted the government to regulate the railroads or take them over completely. These demands became the chief goals of the Populist movement.

The People's Party. In 1891, the farmers' alliances met with delegates from labor and reform groups in Cincinnati, Ohio, and discussed forming a new political party. They formed the People's Party, usually called the Populist Party, a year later in St. Louis, Missouri.

In 1892, the party nominated James B. Weaver of Iowa

or president and James G. Field of Virginia for vice president. Their platform called for free silver, government ownership of railroads and telegraph and telephone lines, and many political reforms. The candidates did not win, but they received more than a million popular votes and 22 electoral votes. Nine Populists were elected to Congress.

In 1896, the Democratic Party nominated William Jennings Bryan of Nebraska for president. His platform included free silver and other Populist demands. The Populists joined the Democrats in supporting Bryan, but he lost to William McKinley, the candidate of the Republican Party. The People's Party started to decline, and it disappeared by 1904.

Influences of populism. Although the People's Party faded away, many of its goals were adopted by the progressive movement and later became law (see **Progressive movement**). These goals included direct election of U.S. senators and the *initiative and referendum,* a process by which voters propose a law and vote on it. Other reforms supported by the Populists included the graduated income tax, which taxes higher incomes more heavily than lower ones, and the 8-hour workday.

Today, the word *populist* is often used to describe a politician who opposes party leaders and appeals directly to the public for support. Most of the so-called "new populists" come from rural areas, and traditional politicians regard them as outsiders. Many leaders with widely varying philosophies have been called populists. Since the 1960's, they have included President Jimmy Carter, Senator George S. McGovern of South Dakota, Governor George C. Wallace of Alabama, and Vice President Hubert H. Humphrey. Karel D. Bicha

Porcelain, *PAWR suh lihn,* is a type of ceramics highly valued for its beauty and strength. It is often called *china,* or *chinaware,* because it was first made in China. Porcelain is characterized by whiteness, a delicate appearance, and *translucence* (ability to let light through). Because it is the hardest ceramic product, porcelain is used for electrical insulators and laboratory equipment. However, porcelain is known primarily as a material for high-quality vases and tableware, as well as for figurines and other decorative objects. The type of porcelain that is used for such purposes produces a bell-like ring when struck.

Porcelain differs from other types of ceramics in its ingredients and in the process by which it is produced. Two common types of ceramics—earthenware and stoneware—are made from a single natural clay, which is then *fired* (baked). In many cases, the object is coated with a glassy substance called *glaze.* Firing at a low temperature produces earthenware, a porous material. Earthenware can be made waterproof by glazing. Firing at a high temperature produces stoneware, a hard, heavy material. Stoneware is nonporous without glazing.

Metropolitan Museum of Art, New York City

A Chinese vase features a deep blue *underglaze,* a design painted on the surface before the porcelain is glazed. This vase was made between 1426 and 1435, during the Ming dynasty.

Unlike earthenware and stoneware, porcelain is basically made from a mixture of two ingredients—*kaolin* and *petuntse. Kaolin* is a pure white clay that forms when the mineral feldspar breaks down. *Petuntse* is a type of feldspar found only in China. It is ground to a fine powder and mixed with kaolin. This mixture is fired at temperatures from about 2280 to 2640 °F (1250 to 1450 °C). At these extreme temperatures, the petuntse *vitrifies*—that is, it melts together and forms a nonporous, natural glass. The kaolin, which is highly resistant to heat, does not melt and therefore allows the item to hold its shape. The process is complete when the petuntse fuses itself to the kaolin.

Kinds of porcelain

There are three main kinds of porcelain: (1) hard-paste porcelain, (2) soft-paste porcelain, and (3) bone china. The differences between these types of porcelain are based on the material from which they are made. This material is called the *body* or *paste.*

Hard-paste porcelain, which is sometimes called *true porcelain* or *natural porcelain,* has always been the model and ideal of porcelain makers. It is the type of porcelain first developed by the Chinese from kaolin and petuntse. Hard-paste porcelain resists melting far better than other kinds of porcelain. For this reason, it can be fired at higher temperatures. These hot temperatures cause the body and the glaze to become one. When hard-paste porcelain is broken, it is impossible to

distinguish the body from the glaze.

The proportions of kaolin and petuntse in hard-paste porcelain may vary. The porcelain is said to be *severe* if the percentage of kaolin is high, and *mild* if the percentage of kaolin is low. Most collectors of porcelain prefer mild porcelain because of its mellow, satiny appearance. In comparison, severe porcelain may seem harsh and cold.

Soft-paste porcelain, sometimes called *artificial porcelain,* was developed in Europe in an attempt to imitate Chinese hard-paste porcelain. Experimenters used a wide variety of materials in their efforts to produce a substance that was hard, white, and translucent. They eventually developed soft-paste porcelain by using mixtures of fine clay and glasslike substances. These materials melt at the high temperatures used in making hard-paste porcelain. For this reason, soft-paste porcelain is fired at lower temperatures and does not completely vitrify—that is, it remains somewhat porous. Breaking a piece of soft-paste porcelain reveals a grainy body covered with a glassy layer of glaze.

Although soft-paste porcelain was invented in imitation of true porcelain, it has merits of its own. Most of it is creamy in tone, and some people prefer this color to pure white. In addition, the colors used to decorate it merge with the glaze to produce a soft, silky effect that appeals to many collectors.

Bone china is basically made by adding *bone ash* (burned animal bones) to kaolin and petuntse. English porcelain makers discovered this combination of ingredients about 1750, and England still produces nearly all the world's bone china. Though not as hard as true porcelain, bone china is more durable than soft-paste porcelain. The bone ash greatly increases the translucence of the porcelain.

Decorating porcelain

A piece of porcelain is shaped on a potter's wheel or in a mold. After this stage, the porcelain worker may decorate it by (1) surface modifications, (2) painting, or (3) transfer printing.

Surface modifications are achieved by *incising* (carving), *perforating* (poking holes), and *embossing* (applying raised designs). A well-known method of embossing porcelain is to apply a mixture of water and clay, called *slip,* to the item with a brush. *Relief designs* (three-dimensional effects) are usually molded separately and then attached to the porcelain.

The Metropolitan Museum of Art, New York City

A Sèvres tray made in 1767 shows the brilliant colors and gilding typical of this French porcelain. The white panel painted with birds in a landscape also became a common Sèvres design.

Painting the porcelain surface may be done in several ways. One method is to use a colored glaze, such as the famous Chinese *celadon.* This glaze is a soft gray-green color. Another type of decoration is *underglaze* (designs painted on a piece before it is glazed). A deep blue made from the metal cobalt is the most dependable color used for underglazing. Cobalt blue has been widely used both in China and in Europe. See **China** (picture: Fine white porcelain).

Paints that are applied over the glaze are commonly called *enamels.* A large variety of enamel colors were perfected at an early period. Most of them are made from metallic oxides, such as iron, copper, and manganese. Enamel colors require a second firing to make them permanent.

Porcelain painting in Europe differed greatly from porcelain painting in China. Chinese decorators separated each color from the next with a dark outline, but European artists blended colors together with no separating line. In addition, Europeans used decorations purely for their artistic value, but Chinese decorations were symbolic. For example, a pomegranate design symbolized a wish for many offspring because a pomegranate has many seeds.

Transfer printing revolutionized the porcelain industry in 1756 by enabling workers to decorate wares much faster than they could by hand. In this process, a design is engraved on a copper plate, inked with ceramic color, and transferred to tissue paper. While the color is still wet, the tissue paper is pressed against a porcelain object, leaving the design on its surface.

History of porcelain

Oriental porcelain. The Chinese probably made the first true porcelain during the Tang dynasty (618-907). The techniques for combining the proper ingredients and firing the mixture at extremely high temperatures gradually developed out of the manufacture of stoneware. During the Song dynasty (960-1279), Chinese emperors started royal factories to produce porcelain for their palaces. Since the 1300's, most Chinese porcelain has been made in the city of Jingdezhen.

For centuries, the Chinese made the world's finest porcelain. Collectors regard many porcelain bowls and vases produced during the Ming dynasty (1368-1644) and Qing dynasty (1644-1912) as artistic treasures. Porcelain makers perfected a famous blue and white underglazed procelain during the Ming period. Painting over the glaze with enamel colors also became a common decorating technique at this time. During the Qing period, the Chinese developed a great variety of patterns and colors and exported porcelain objects to Europe in increasing numbers.

By the 1100's, the secret of making porcelain had spread to Korea and to Japan in the 1500's. Workers in these countries also created beautiful porcelain objects. A Japanese porcelain called Kakiemon was first produced during the 1600's. It features simple designs on a

white background. Another well-known Japanese porcelain called Imari ware, or Arita, is famous for its dense decorations in deep blue and red.

European porcelain. As early as the 1100's, traders brought Chinese porcelain to Europe, where it became greatly admired. However, it was so rare and expensive that only wealthy people could afford it.

As trade with the Orient grew during the 1600's, porcelain became popular with the general public. The custom of drinking tea, coffee, and chocolate became widespread and created a huge demand for porcelain cups and saucers. European manufacturers responded by trying to make hard-paste porcelain themselves, but for a long time they failed to discover the secret. Nevertheless, some of their experiments resulted in beautiful soft-paste porcelain. The first European soft-paste porcelain was produced in Florence, Italy, about 1575.

By the 1700's, porcelain manufactured in many parts of Europe was starting to compete with Chinese porcelain. France, Germany, Italy, and England became the major centers for European porcelain production.

French porcelain. France became famous during the 1700's as the leading producer of soft-paste porcelain. The first factories were established at Rouen, St. Cloud, Lille, and Chantilly.

The most celebrated type of soft-paste porcelain was first produced at Vincennes in 1738. In 1756, the factory was moved to the town of Sèvres. Its soft-paste porcelain became known as Sèvres. The earliest Sèvres had graceful shapes and soft colors. Sèvres pieces produced from 1750 to 1770 were decorated with brilliant colors and heavy gilding. Many of these pieces had richly colored backgrounds and white panels painted with birds, flowers, landscapes, or people. Sèvres is also noted for its fine figurines of *biscuit* (unglazed porcelain).

Beginning in 1771, a hard-paste porcelain industry developed near Limoges, where kaolin deposits had been discovered. By the 1800's, Limoges had become one of the largest porcelain centers in Europe. An American named David Haviland opened a porcelain factory at Limoges in 1842 to make tableware for the American market. Haviland porcelain features soft colors that blend together and small floral patterns.

Metropolitan Museum of Art, New York City

A Meissen figurine of the mid-1700's was created by Johann Kändler, a German artist famous for his beautifully designed and decorated porcelain figures of people and animals.

German porcelain. A German chemist named Johann Friedrich Böttger discovered the secret of making hard-paste porcelain in 1708 or 1709. This discovery led to the establishment of a porcelain factory in Meissen in 1710. Meissen porcelain is sometimes called Dresden because Böttger first worked near the city. For nearly a century, it surpassed in quality all other hard-paste porcelain made in Europe.

The great success of Meissen porcelain can be partly attributed to the fine artists who decorated it. They painted the wares with an amazing variety of colors and designs. Johann Höroldt (or Herold), who became chief painter in 1720, produced beautiful Chinese and Japanese as well as European designs. Johann Kändler, who worked from about 1730 to 1770, is famous for his exquisite figures of animals and people.

Political disorder in Germany and competition from Sèvres porcelain drove the Meissen factory into decline during the late 1700's. It continued to operate but did not make wares of the same artistic quality.

English porcelain. England is well known as the center for the production of bone china. Before the invention of bone china, the English manufactured fine soft-paste porcelain at Chelsea, Bow, and Derby. Most of this English porcelain was styled after Oriental and Continental designs.

Worcester porcelain, first produced in 1751, is one of the oldest and best English porcelains. During its early years, the Worcester factory produced soft-paste porcelain, much of it decorated with Chinese designs in blue underglaze. Since the 1760's, it has manufactured bone china in a wide variety of colors and patterns.

Josiah Spode developed a bone china paste that became the standard English paste in 1800. Spode china featured a large number of designs but was especially noted for its exotic birds.

Most of the famous English Wedgwood ware is not porcelain at all, but earthenware or stoneware. Nevertheless, its classical Greek figures and reliefs became enormously popular and had a great influence on porcelain designs throughout Europe.

Modern porcelain. Technical advances enabled the porcelain industry to produce porcelain in large quantities. Today, extensive porcelain making is carried out in the United States, Europe, and Japan. Some notable examples of fine contemporary porcelain are American Lenox, German Rosenthal, and Japanese Noritake.

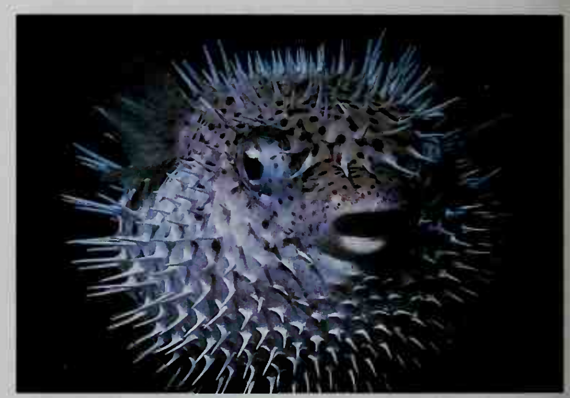
Porcupine, *PAWR kyuh pyn,* is an animal that has long, soft hairs and strong, stiff quills on its back, sides, and tail. Porcupine quills are long, sharp bristles of hairs that are *fused* (grown together). Porcupines defend themselves by striking attackers with their quilled tails. The quills come out easily and stick into the attacker's flesh. The porcupine grows new quills to replace the ones lost. Porcupines cannot shoot quills at their enemies, as some people believe. In some kinds of porcupines, the tip of each quill is covered with tiny,

backward-pointing projections called *barbs.* The barbs hook into the flesh, and the quills are difficult to remove. Porcupine victims may die from infections caused by germs on the quills, or from damage to a vital organ. Quills may even stick in an attacker's jaw, making the animal unable to open its mouth and causing starvation. *Fishers,* large members of the weasel family, attack porcupines by flipping them over onto their backs.

Porcupines are *rodents* (gnawing animals). Biologists classify them as *Old World porcupines* and *New World porcupines.* Old World porcupines live in Africa, southeastern Asia, India, and southern Europe. Most kinds of Old World porcupines grow about 3 feet (91 centimeters) long, including the tail. They make their homes in tunnels in the ground and do not climb trees.

New World porcupines live in North and South America. These animals spend much time in trees. Several South American porcupines, called *coendous,* can even hang by their tails. Only one kind, the *North American porcupine,* lives in North America. North American porcupines are about 3 feet (91 centimeters) long and weigh about 20 pounds (9 kilograms). Their yellowish-white quills are 2 to 3 inches (5 to 8 centimeters) long. Their fur is brownish-black. North American porcupines live chiefly in forests of *coniferous* (cone-bearing) trees, such as pines and firs. They eat green vegetation and tree bark. They often climb trees to strip the bark from the upper part of the tree. They may kill a tree in this way.

Female North American porcupines give birth to a single offspring in the spring. The babies have quills at birth. North American porcupines are often incorrectly called *hedgehogs.* True hedgehogs live only in the Eastern Hemisphere. The flesh of the North American porcupine is edible, but few people consider it tasty.



Leonard Lee Rue III, Bruce Coleman Ltd.

The North American porcupine is protected by yellowish-white quills. Its food includes tree bark.

Scientific classification. Old World porcupines make up the family Hystricidae. New World porcupines make up the family Erethizontidae. North American porcupines are *Erethizon dorsatum.* Hugh H. Genoways

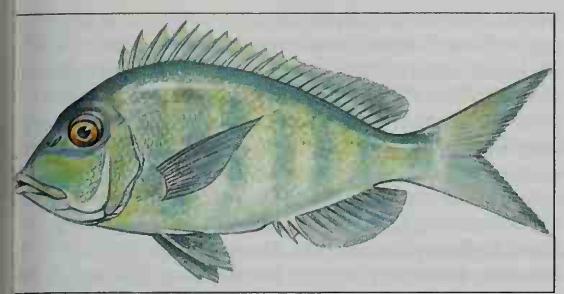
Porcupinefish, also called *spiny puffer,* is a kind of fish that has sharp, protective spines covering its body. When an enemy or intruder scares a porcupinefish, the fish may enter a hole or crack in a rock and fill its stomach with water. The water causes the fish to puff up like a balloon and makes its spines stick out. If taken out of the water, the porcupinefish puffs up by filling its stomach with air. In most species, the spines lie flat against the body when the fish are calm.

© David Hall, Photo Researchers



A porcupinefish has strong, sharp spines on its body. It fills its stomach with water to make the spines stick out.

There are 15 species of porcupinefish. Most are bluish, brownish, grayish, or greenish with yellow or white bellies. Some species have round black or brown spots. Porcupinefish grow to an average length of 10 to 12 inches (25 to 30 centimeters). All porcupinefish have two large teeth, one upper and one lower, that stick out like a beak. They use their teeth to feed on sea urchins, small crabs, and other hard-shelled prey. Porcupinefish live in tropical seas.

Scientific classification. Porcupinefish make up the porcupinefish family, Diodontidae. Leighton R. Taylor, Jr.

See also **Fish** (picture: The porcupinefish).

Pore is the tiny opening of a skin gland. The glands are like little sacks set deep in the skin. The cells inside the sacks produce sweat if the gland is a sweat gland, and oil if it is a sebaceous gland. The face has many sebaceous glands. The oil that these glands produce is normally a liquid. *Blackheads* form if the oil *cakes* (becomes solid) within the pores. If the skin around the blackheads becomes inflamed, acne pimples result. If certain kinds of bacteria get into the pores, they cause boils. A skin rash known as *prickly heat* develops when sweat glands are blocked up. See also **Acne; Perspiration; Prickly heat; Skin.** Paul R. Bergstresser

WORLD BOOK illustration by John F. Eggert

The jolthead porgy lives in Atlantic coastal waters.

Porgy, *PAWR gee,* is a fish that lives in shallow areas of warm seas. The body of a porgy is oblong and has flattened sides. Most porgies are silvery in color. Porgies are good food fish. They are caught both for sport and for commercial use.

There are more than 100 species of porgies. Several of them live along the coasts of North America. The *jolthead porgy* is probably the best known of these. It lives in the Caribbean Sea and in the Atlantic Ocean from Brazil to New England. The jolthead also is one of the largest porgies. It grows to a length of 2 feet (60 centimeters) and weighs 8 to 10 pounds (3.6 to 4.5 kilograms). John E. McCosker

Scientific classification. Porgies belong to the porgy family, Sparidae. The jolthead porgy is *Calamus bajonado.*

Porifera. See **Sponge.**

Pork is the meat from hogs. People throughout the world eat more pork than any other kind of meat. In the United States, pork ranks third in popularity, behind chicken and beef. Americans eat an average of 61 pounds (30 kilograms) of pork per person annually.

Pork is sold to consumers as fresh meat or in the form of *processed meats.* Processed meats are *cured* (treated) with a solution of salt and a chemical called sodium nitrite and then are smoked, baked, or dried. Curing and smoking give these meats a special flavor and help keep them from spoiling quickly or losing their color. The chief processed meats produced from pork are bacon, ham, and sausage. Fresh cuts of pork include pork chops, roasts, and spare ribs.

Pork contains many *nutrients* (nourishing substances) needed by the human body. It is an excellent source of vitamins, especially *thiamine* (vitamin B_1). The protein in pork provides the *amino acids* needed to build and maintain body tissue (see **Amino acid**). Pork also contains such essential minerals as copper, iron, phosphorus, and zinc. Pork fat is a good source of energy and of certain *fatty acids* the body cannot produce (see **Fat**).

Fresh pork sometimes contains the *larvae* (young) of a microscopic worm called *trichina.* A person who eats live trichina larvae may develop a disease called *trichinosis.* Thoroughly cooking fresh pork kills any trichina larvae that the meat may contain. Larry L. Borchert

Bacon	Hog	Meat	Sausage
Ham	Lard	Meat packing	Trichina

Pork barrel is an American slang expression for a government treasury. It originated in the 1800's, when the word *pork* became slang for government money spent on local projects. At that time, farmers preserved pork by keeping it salted in barrels, and so bills distributing this money were called "pork barrel bills."

A legislator customarily votes for expenditures in other districts, even though he or she may think them unnecessary, to have legislators from those districts vote for projects in his or her district (see **Logrolling**). Defenders of this system point out that pork-barrel projects, such as river and harbor improvements, increase the country's wealth by providing more public facilities. However, excessive pork-barrel practices have led to movements to give the president of the United States the power to veto individual items in a spending bill without killing the whole bill. In 1996, Congress enacted a law that gave the president such a power beginning in 1997. But the Supreme Court of the United States ruled the law unconstitutional in 1998. Peter Woll

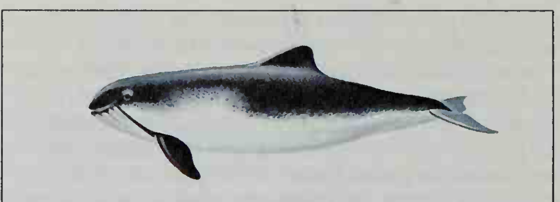
Pornography. See **Obscenity and pornography.**

Porosity, *paw RAHS uh tee,* is the existence of many small holes or spaces in a material. In some porous materials, such as charcoal, earthenware pottery, and sponges, these holes connect. Gases and liquids can pass through the holes. In other porous materials, the small spaces inside are separated from each other by solid material. Bricks and certain types of foam rubber are examples of this kind of porous material. These materials are usually able to absorb liquids and gases.

Porosity is desirable in some materials and undesirable in others. For example, porous filters of charcoal can remove impurities from the air. However, porosity in iron castings reduces the strength of the metal.



On the atomic scale, every material is considered porous because there is much free space between their atoms or molecules. For example, the spaces between the atoms of the metal palladium are large enough for hydrogen atoms to move about. John B. Butt

See also **Diffusion; Molecule.**

Porphyry, *PAWR fur ree* (A.D. 232 to 233-305?), was one of the leaders in the Neoplatonic school of philosophy. He was the student of Plotinus, the most important Neoplatonist, and published an edition of Plotinus's *Enneads* and a *Life of Plotinus.* Porphyry wrote a great many works but most have been lost or survive only as fragments. He wrote commentaries on works of Plato and Aristotle and his commentary on Aristotle's *Categories* became a standard medieval textbook on logic. Porphyry was born in Syria, studied in Athens, and became a disciple of Plotinus in Rome in 262 to 263. See also **Neoplatonism; Plotinus.** Carl A. Huffman

Porpoise is the name of several sea mammals closely related to dolphins. Porpoises look much like dolphins but are smaller in size. They also differ from dolphins in the shape of the head and teeth. Porpoises have a gently sloping forehead, a rounded snout, and spade-shaped teeth. Dolphins have a steeply sloping forehead, a beaklike snout, and cone-shaped teeth. Porpoises, dolphins, and whales make up a group of mammals called *cetaceans* (pronounced *suh TAY shuhnz*). Scientists classify porpoises, dolphins, and certain whales as a group of cetaceans called *toothed whales.*

Porpoises generally roam cool, coastal waters of the Pacific and Atlantic oceans. They can swim at speeds of about 12 miles (20 kilometers) per hour. They eat small fish and squid. Porpoises usually grow from 4 to 7 feet

WORLD BOOK illustration by James Teason

The harbor porpoise, also called the *common porpoise,* has a dark gray to black back and a pale gray or white belly. It lives primarily in cool coastal waters in the Northern Hemisphere.

(1.5 to 2.1 meters) in length and weigh from 110 to 220 pounds (50 to 100 kilograms).

There are six species of porpoises. The *harbor* or *common porpoise* and the *gulf porpoise* are dark gray to black on the back and pale gray or white on the sides and belly. The *finless porpoise* and *Burmeister's porpoise* are almost entirely gray or black. The *spectacled porpoise* and *Dall's porpoise* have a striking pattern of black and white. Most porpoises have a thick body and a small *dorsal fin* (back fin). Only the finless porpoise lacks a dorsal fin.

Human fishing activities have severely reduced the world's porpoise population. The Gulf of California harbor porpoise is an endangered species because so many have been trapped and accidentally killed in nets set for fish. Similarly, huge nets called *drift nets* have killed tens of thousands of Dall's porpoises. To protect porpoises and other marine life, many countries have agreed to stop using drift nets in ocean waters.

Daniel K. Odell

Scientific classification. Porpoises belong to the family Phocoenidae in the order Cetacea. Burmeister's, common, gulf, and spectacled porpoises belong to the genus *Phocoena.* Burmeister's porpoise is *P. spinipinnis,* the common porpoise is *P. phocoena,* the gulf porpoise is *P. sinus,* and the spectacled porpoise is *P. dioptrica.* Dall's porpoise is *Phocoenoides dalli.* The finless porpoise is *Neophocaena phocaenoides.*

Port is a place where ships and boats load and unload passengers and cargoes. Large, bustling ports have buildings and equipment for receiving, storing, and reshipping goods. Such facilities include wharves, warehouses, tugs, ferries, mechanical loaders and unloaders, and railroad and truck transportation (see **Ship** [Modernization of ports]).

Some ports, such as Cherbourg, France, and Rio de Janeiro, Brazil, stand on natural harbors formed by bays and inlets. Others, such as Los Angeles and Genoa, Italy, are built on artificial harbors protected by breakwaters and jetties. Many great ports lie on rivers far from the sea. Inland ports include London; Montreal; New Orleans; and Bordeaux, France.

Ports may also be classified by their purpose or function. For example, Gibraltar is a naval, or strategic, port. Concarneau, France, is a fishing port. Cape Town, South Africa, serves as a fuel-storage port for ships sailing around the tip of Africa. Kharg Island, Iran, in the Persian Gulf, is a leading petroleum port.

Much United States and Canadian commerce passes through ports on the Great Lakes. Inland waterways make it possible for all but the largest ocean ships to sail from the Atlantic Ocean to Chicago, Toronto, and other Great Lakes ports. Among the chief U.S. ports are Baltimore; Baton Rouge, Louisiana; Charleston, South Carolina; Houston; Long Beach, California; Los Angeles; New Orleans; New York City; Norfolk, Virginia; and Philadelphia. The main ports in Canada include Montreal, Quebec; Sept-Îles, Quebec; Thunder Bay, Ontario; and Vancouver, British Columbia. John F. Wing

Port Arthur, China. See **Lüshun.**

Port Arthur, Ontario. See **Thunder Bay.**

Port-au-Prince, *pawrt oh PRIHNS* (pop. 738,342), is the capital and largest city of Haiti. It lies on the Golfe de la Gonâve (Gulf of Gonave) on Haiti's west coast. For location, see **Haiti** (map).

People from many parts of Haiti sell produce and other goods in Port-au-Prince on sidewalks and in a large marketplace called the Iron Market. Factories produce such goods as cement, processed foods, rum, and textiles. Port-au-Prince has two cathedrals, a university, and many government buildings. It also has large slum areas, where overcrowded and unsanitary conditions reflect the poverty of many residents.

Port-au-Prince was founded in 1749 by French sugar cane planters. France controlled the city until 1804, when Haiti gained independence. Gary Brana-Shute

See also **Haiti** (pictures), **West Indies** (picture: A crowded street market).

Port Authority of New York and New Jersey is a self-supporting corporate agency of the states of New York and New Jersey. It was formed in 1921 to plan and develop terminal and transportation facilities, and to improve and protect the commerce of the port district. The district includes an area of both states within a 25-mile (40-kilometer) radius of the Statue of Liberty. The authority's facilities include bridges, tunnels, marine and inland terminals, airports, heliports, and a rail rapid transit system.

The Port Authority has 12 commissioners—6 from New Jersey and 6 from New York. Each is nominated by his or her state's governor and approved by its senate. The commissioners serve without pay for terms of six years. The Port Authority appears before the Federal Maritime Commission in the interest of the port area. The authority has trade development offices in Chicago, Cleveland, London, New York, and Tokyo. These offices promote commerce through the Port of New York.

Robert E. Paaswell

Port Elizabeth (pop. 303,353; met. area 825,799) is a leading seaport and industrial city in South Africa. It lies on the southern coast of South Africa (see **South Africa** [map]). Products manufactured in Port Elizabeth include automobiles and rubber.

The land that is now Port Elizabeth was once farmed by Xhosa people. Today, Xhosa people form the city's largest African group. The first large group of English settlers to reach South Africa landed at Port Elizabeth in 1820. They settled in and near Grahamstown, northeast of the city. Bruce Fetter

Port Louis, *LOO ihs* or *LOO ee* (pop. 138,482), is the capital, largest city, and leading port of Mauritius, an island country in the Indian Ocean. Port Louis lies in a lowland on the northwest coast of the country's main island, which is also called Mauritius. For location, see **Mauritius** (map). The city's main employers are textile

manufacturers, food-processing plants, shipping companies, and the government. Much sugar, the chief product of Mauritius, is exported from Port Louis.

France ruled Mauritius during the 1700's. The French governor founded Port Louis in 1736 and named it for Louis XV, the king of France. French culture still plays an important part in the city's life. Bruce Fetter

Port Moresby, *MOHRZ bee* (pop. 152,100), is the capital and largest city of Papua New Guinea, a country in the South Pacific Ocean. The city lies on a well-protected harbor on the southeastern coast of the island of New Guinea. For location, see **Papua New Guinea** (map).

Papua New Guinea's national government employs many of Port Moresby's people. The city has an international airport and a university and other training institutions. Important industries in Port Moresby include construction and food processing.

Port Moresby was established by the British shortly after British explorer John Moresby reached the site in 1873. During World War II (1939-1945), it served as an Allied military base and was bombarded by Japanese forces. The city had fewer than 5,000 people before the war but has since grown rapidly. David A. M. Lea

See also **New Guinea** (picture); **Papua New Guinea** (picture).

Port of entry is any place established by a government to receive aliens, imports, and customs duties. Customs officers admit all imported goods, collect duties, and enforce the customs and navigation laws. A person who unloads foreign goods at a port that does not have a custom house is guilty of smuggling.

Ports of entry may include seaports, lakeports, and airports situated at the borders or throughout the country. A custom house may be located wherever goods of other countries are held until they are distributed to local trade. Robert M. Stern

Port-of-Spain (pop. 59,649) is the capital and trade center of Trinidad and Tobago, an island country that lies off the northeast coast of Venezuela. The city lies near the foothills of the Northern Range of mountains on the island of Trinidad (see **Trinidad and Tobago** [map]).

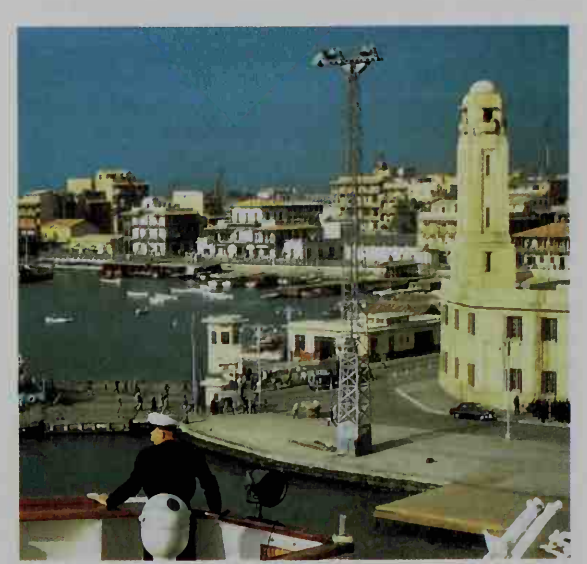
The city's deep, sheltered harbor helps make it the port through which most of Trinidad's exports and imports are handled. Port-of-Spain also serves as the country's main commercial and industrial center. The city's architecture and other cultural features reflect the variety of its African, Asian Indian, and European ethnic heritage. The city was founded about 1560 by Spanish colonists. Gerald R. Showalter

See also **Trinidad and Tobago** (picture).

Port Royal. See **Annapolis Royal; Canada** (National historic sites).

Port Said, *sah EED* (pop. 460,000), is an Egyptian city that lies at the junction of the Suez Canal and the Mediterranean Sea. For location, see **Egypt** (political map). Its name in Arabic is *Bur Said.*

Port Said was founded in 1859 as a camp for workers who built the Suez Canal. After the canal opened in 1869, the city became one of the world's busiest ports. The canal was closed during the Arab-Israeli War of 1967, and the city lost its importance as a port. Egypt reopened the canal in 1975 and set up a free trade zone to encourage trade there (see **Free trade zone**). Products of Port Said include leather, refined petroleum, salt, and textiles. Robert L. Tignor



Port Sudan, *soo DAN* (pop. 206,727), is the main port of Sudan. It lies in northeast Sudan on the coast of the Red Sea (see **Sudan** [map]). Port Sudan was founded in 1906. It is a major commercial and shipping center, with a fine harbor and modern docking facilities. Most of Sudan's foreign trade moves through the port. Exports from Port Sudan include beans, cattle, cotton and cottonseed, gum arabic, hides, oilseeds, and sheep. Heavy machinery and manufactured products are among the chief imports. Kenneth J. Perkins

Portage is the carrying of goods or boats overland between two bodies of water, or around some obstacle such as a waterfall or river rapids. The term *portage* is also used for the land route over which the goods are carried. North American Indians traveled long distances by portaging between rivers and lakes. The Indians traveled as far upstream as their boats could go. The Indians then carried their canoes and goods overland to the next stream or lake, where they resumed the trip by water.

Portage la Prairie, Manitoba (pop. 12,976), serves as the market city for the surrounding *Portage Plains* farming region. For the location of the city, see **Manitoba** (political map). Portage la Prairie ranks as one of Manitoba's largest retail centers. The city received its name from an old *portage* (route between two bodies of water) used by fur traders.

Settlement in the area began in 1738, when French traders built Fort La Reine there. Permanent settlement at the site of the present city began in 1851. In 1868, the English-born land developer Thomas Spence organized the settlement into a colony called Manitobah. Portage la Prairie became a town in 1880, when the Canadian Pacific Railroad arrived. The town achieved city status in 1907. J. M. Bumsted

Porter, Cole (1891-1964), was an American songwriter famous for his witty lyrics and for imaginative melodies.

Photri from Marilyn Gartman

Port Said is one of Egypt's busiest ports. It lies at the junction of the Suez Canal and the Mediterranean Sea.

Porter's most popular songs are sophisticated, satirical, and sometimes silly. They include "Begin the Beguine," "Night and Day," "I've Got You Under My Skin," "Anything Goes," "Love for Sale," and "You're the Top."

Cole Albert Porter was born in Peru, Indiana. He showed an early talent for music and had a song published when he was only 11 years old. Several more of his songs were published while he was a student at Yale and Harvard universities.

In 1920 and 1921, Porter studied music in Paris. His experiences there provided him with the material for *Paris* (1928), his first Broadway success. He used the life of wealthy people as the theme for many of his musicals. These shows include *Fifty Million Frenchmen* (1929), *Gay Divorce* (1932), and *Anything Goes* (1934).

In 1937, Porter injured his legs severely in a horseback-riding accident. He used a wheelchair for the rest of his life but, despite constant pain, wrote many more successful musicals. Among them were *Du Barry Was a Lady* (1939), *Panama Hattie* (1940), *Mexican Hayride* (1944), *Kiss Me, Kate* (1948), *Can-Can* (1953), and *Silk Stockings* (1955). He also wrote the scores for the motion pictures *Born to Dance* (1936), *Rosalie* (1937), and *High Society* (1956). Ken Bloom

Porter, David (1780-1843), was a United States naval officer who fought in the War of 1812. He was captain of the *Essex,* which operated in the Pacific Ocean and was the first warship to fly the U.S. flag in those waters. In the war, Porter almost entirely destroyed the British whaling industry in the Pacific. Porter's informally adopted son, David G. Farragut, who later became the Navy's first admiral, also made the voyage (see **Farragut, David Glasgow**). Later, Porter surrendered to the British ships *Cherub* and *Phoebe.* He returned home as a hero and in 1815 became a Navy commissioner.

In 1823, Porter resigned this post to lead an expedition against pirates in the West Indies. When one of his officers was insulted at Fajardo, Puerto Rico, Porter forced Puerto Rican officials to apologize. As a result, a court-martial in 1825 found him guilty of disobeying orders and suspended him for six months. He resigned and served from 1826 to 1829 with the Mexican Navy, which he helped reorganize. Porter returned to the United States in 1829 and was appointed U.S. consul general to Algiers. He later served as a diplomat in Turkey.

Porter was born in Boston. At the age of 18, he joined the U.S. Navy as a midshipman. His son David Dixon Porter was also a noted U.S. naval officer (see **Porter, David Dixon**). Michael J. Crawford

Porter, David Dixon (1813-1891), was a United States naval officer who became noted for his service during the American Civil War (1861-1865). In the Union attack on New Orleans in 1862, Porter directed a mortar squadron under the command of his adopted brother, David Farragut. Porter fired mortar shells at Fort Jackson and Fort Saint Philip for five days. Then Farragut went past the forts and destroyed the Confederate fleet. The forts surrendered to Porter a few days later.

Later in 1862, Porter commanded the U.S. Navy's upper Mississippi squadron. In 1863, he helped the Army capture the Arkansas Post, also called Fort Hindman, in Arkansas. In addition, he aided in the siege of Vicksburg, Mississippi, and became a rear admiral for this action. Porter became commander of the North Atlantic Blockading Squadron in 1864. The squadron captured many merchant ships that tried to enter or leave Southern ports. In 1865, as commander of about 60 naval vessels, the largest fleet assembled during the war, Porter took part in the capture of Fort Fisher, North Carolina.

Porter served as superintendent of the U.S. Naval Academy from 1865 to 1869. He became a vice admiral in 1866. In 1870, he succeeded Farragut as an admiral, becoming the second person in the history of the Navy to hold that rank. Porter headed the Board of Inspection from 1877 until his death.

Porter was born in Chester, Pennsylvania. At the age of 10, he went with his father, David Porter, to fight pirates in the West Indies. He also served with his father as a midshipman in the Mexican Navy (see **Porter, David**). At the age of 16, Porter joined the U.S. Navy as a midshipman. He commanded the vessel *Spitfire* during the Mexican War (1846-1848). John F. Marszalek

Porter, Fitz-John (1822-1901), an American soldier, became the central figure in a celebrated military inquiry during the American Civil War. In August 1862, as a major general, Porter commanded a Union corps in the second Battle of Bull Run (also called Manassas). The corps was part of an army led by General John Pope. During the battle, Porter refused to obey Pope's order to attack Confederate forces. Porter believed such an attack would destroy the Union army. The Union forces eventually lost the battle, and Pope charged Porter with disobedience, disloyalty, and misconduct. In January 1863, a court-martial found Porter guilty and dismissed him from the army, though the evidence was confused and the fairness of the trial questionable. Porter had pleaded innocent. In 1879, a board of officers reopened the case and ruled in Porter's favor. The United States Congress restored Porter's rank in 1886.

Porter was born in Portsmouth, New Hampshire. He graduated from the U.S. Military Academy in 1845. James E. Sefton

Porter, Katherine Anne (1890-1980), was an American writer noted mainly for her short stories. Her *Collected Stories* (1965) won the 1966 Pulitzer Prize for fiction. Porter's most famous stories express political and social liberalism. Many contain religious symbolism, reflecting her Roman Catholic background. She made the setting for most of her short stories in a specific place, such as the American South, Mexico, or Europe.

Porter's major collections are *Flowering Judas* (1930); *Pale Horse, Pale Rider* (1939), a collection of three short novels; and *The Leaning Tower* (1944). Her only novel, *Ship of Fools* (1962), is a moral allegory that describes an ocean voyage from Mexico to Germany during the early 1930's. The story reflects the social and political turmoil of that time. *The Collected Essays and Occasional Writings of Katherine Anne Porter* (1970) is a collection of nonfiction. Porter was born in Indian Creek, Texas, near Brownwood. Arthur M. Saltzman

Porter, William Sydney. See Henry, O.

Portland, Maine (pop. 64,249; met. area pop. 243,537), has one of the finest harbors on the Atlantic Coast and is closer to Europe than any other transatlantic port in the United States. It is the largest city in Maine and a leading industrial and commercial center. During World War II (1939-1945), Portland was the base for the North Atlantic Fleet of the U.S. Navy.

Portland lies on the southwest coast of Maine. The city covers about 21 square miles (54 square kilometers). It is built on a narrow peninsula with a maximum height of 187 feet (57 meters) above sea level. It overlooks Casco Bay to the east. The bay has many islands, some of which are part of Portland. Mount Washington and the other mountains of the Presidential Range, to the northwest, tower in the distance. Between these peaks and the coast is a network of lakes and valleys to which Portland is the eastern gateway. To the south is Old Orchard Beach, a long stretch of smooth sand. For Portland's monthly weather, see **Maine** (Climate).

Portland is the home of a branch of the University of Maine and schools for the deaf and blind. Museums in the city include the Portland Museum of Art and the Maine Historical Society Museum. Next to the historical museum is the old home of poet Henry Wadsworth Longfellow, who was born in Portland.

City hall, the Custom House, the Public Safety Building, and federal, district, and state courts are clustered together in the heart of Portland's downtown area. An auditorium in city hall contains one of the largest organs in the world. The organ was a gift from the publisher Cyrus H. K. Curtis, who was born in Portland. In the 1970's and early 1980's, the city's downtown area was revived as a center for shopping and services. The Old Port is a shopping area located near Portland's waterfront.

Portland has many small factories. Oil, fish, and dry goods such as scrap metal are among the leading products shipped from the port. Tankers bring oil to the port for the Portland-Montreal pipeline to Canada.

About 28 million tons (25 million metric tons) of products are shipped in and out of the harbor of Portland yearly, making it one of the chief ports on the Atlantic Coast. Passenger cruise ships also make regular stops at Portland's harbor.

Portland was founded in 1632. It was first called *Machigonne,* and later *Falmouth.* The settlement was destroyed twice by Indians. During the Revolutionary War in America (1775-1783), the British bombarded the port. In 1791, a lighthouse was erected at what is now the adjacent town of Cape Elizabeth. The lighthouse, called Portland Head Light, is standing today. A fire in 1866 ruined much of Portland, but it was soon rebuilt. A large number of Victorian-style buildings erected when the city was rebuilt have been preserved. In 1899, the city of Deering was annexed. In 1993, the Casco Bay island of Long Island seceded from Portland. Portland is the seat of Cumberland County and has a council-manager form of government. Linda R. White

See also **Maine** (picture).

Portland, Oregon (pop. 529,121; met. area pop. 1,918,009), is the state's largest city and its major center of industry and trade. It also is an important West Coast port. Portland is on Oregon's northern border, near the junction of the Columbia and Willamette rivers. For the location of Portland, see **Oregon** (political map). About 55 percent of Oregon's people live in the city's metropolitan area.

Two New England land developers, Asa L. Lovejoy of Boston and Francis W. Pettygrove of Portland, Maine, founded Portland in 1845. Both believed that a great port city would someday stand on the site. Lovejoy and Pettygrove each wanted the new settlement to be named for his own home city. To settle the matter, they flipped a coin. Pettygrove won.

Portland is known as the *City of Roses* because of its many public and private rose gardens. Roses thrive in Portland's mild, moist climate. For the monthly weather in the city, see **Oregon** (Climate).

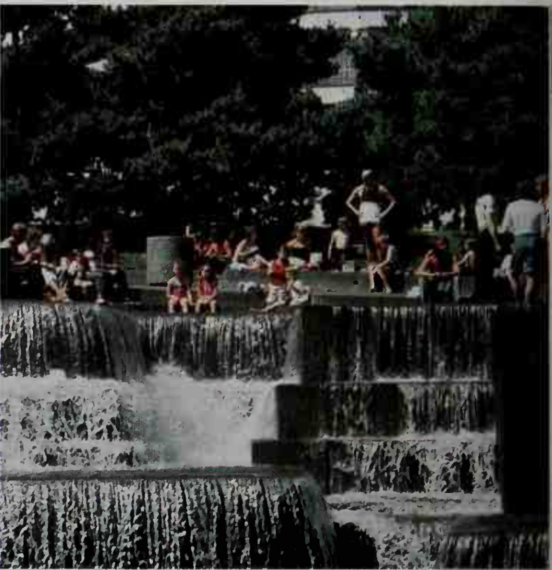
The city. Portland, the county seat of Multnomah County, lies at the northern end of the fertile Willamette Valley. Mountains of the Coast Range rise 20 miles (32 kilometers) west of the city. The view to the east of Portland features snow-capped Mount Hood, about 50 miles (80 kilometers) away in the Cascade Range. Portland covers about 112 square miles (290 square kilometers), including 6 square miles (15 square kilometers) of inland water. Portland and Vancouver, Washington, form a metropolitan area with a land area of 5,028 square miles (13,022 square kilometers). The Portland-Vancouver and Salem metropolitan areas make up the Portland-Salem Consolidated Metropolitan Area. This area has a population of 2,265,223 and a land area of 6,954 square miles (18,011 square kilometers).

Portland's main shopping district lies on the west bank of the Willamette River. This downtown area includes the 40-story First Interstate Bank of Oregon Building, Oregon's tallest building. The nearby Civic Auditorium Forecourt and Fountain has waterfalls and wading pools.

About 93 percent of Portland's people were born in the United States. African Americans, American Indians, and people of East Asian ancestry make up about 14 percent of the population.

Economy. The more than 2,800 manufacturing plants in the Portland metropolitan area employ about half of the area's workers. Industries in the area make computers and electronic equipment, food products, lumber and wood products, machinery, paper products, textiles, and transportation equipment. Other manufacturing activities include food processing and metal processing. Portland is the center of finance and medicine for Oregon and southwestern Washington.

The Port of Portland handles more automobiles, grain, lumber, and other nonfluid cargo than any other port in the Pacific Northwest. The port handles about 28 million tons (25 million metric tons) of cargo annually. Portland also leads the Pacific Northwest in wholesale trade. Barge and cargo ship lines, rail freight lines, and passenger trains serve the city. Portland International Airport lies about 6 miles (10 kilometers) northeast of the downtown area. Portland has one daily newspaper, *The Oregonian.*



Education and cultural life. Portland's public school system includes more than 80 elementary and middle schools and 12 high schools. The city also has more than 170 parochial and private schools.

Portland State University, with more than 14,000 students, is the city's largest four-year institution of higher learning. Other colleges and universities in Portland include Lewis and Clark College, Reed College, the University of Portland, and Western States Chiropractic College. The Oregon Health Sciences University in Portland includes the state's medical and dental schools. The city's libraries include the main building and 14 branches of the Multnomah County Library.

D. C. Lowe, FPG

Portland is the largest city in Oregon and one of the West Coast's chief ports. The downtown business district, *above,* lies on the west bank of the Willamette River.

© Lee Poster, Bruce Coleman Inc.

Glistening waterfalls and wading pools help provide an attractive setting at the Civic Auditorium Forecourt and Fountain in downtown Portland.

Portland has a civic theater, a performing arts center, an opera company, and a symphony orchestra. The city's museums include the Oregon Historical Society, the Oregon Museum of Science and Industry, the Portland Museum of Art, and the World Forestry Center. Portland has 148 parks. Forest Park, a hilly, 6,000-acre (2,400-hectare) wilderness, ranks as the largest woodland within a U.S. city. The International Rose Test Gardens have won fame for the beauty and variety of their flowers.

Annual events in the city include the Rose Festival in June. The Portland Trail Blazers of the National Basketball Association play their home games in the Rose Garden arena.

Government. Portland has a commission form of government. The voters elect a mayor and four commissioners, all to four-year terms. Each of these five officials heads one or more departments of the city government. Together, they make up the City Council, which votes on city laws. Portland gets most of its revenue from business licenses and property and utility taxes.

History. Chinook Indians lived in what is now the Portland area before white people first arrived there. In 1829, a French-Canadian trapper named Etienne Lucier built the first log cabin in the Portland area. Two land developers from New England, Asa L. Lovejoy and Francis W. Pettygrove, founded Portland in 1845. In 1851, when Portland was incorporated, it had 821 people and was the largest town in the Pacific Northwest.

Portland grew steadily from 1850 to 1900. Settlers came by covered wagon to Portland and nearby farm areas. Portland became a trade center for fur, grain, lumber, canned salmon, and wool. In 1883, rail lines linked it with the East. The improved transportation encouraged the growth of manufacturing in the area.

Between 1900 and 1910, Portland's population grew from 90,426 to 207,214. The rural population of the Pacific Northwest also increased, providing new markets for Portland manufacturers. The city served as a supply point for gold miners in Alaska and the Yukon Territory of Canada during the late 1890's and early 1900's. A world's fair, the Lewis and Clark Centennial Exposition of 1905, brought 3 million visitors to Portland. Many of them settled in the city.

For many years, the lumber and wool products industries provided about two-thirds of Portland's jobs. But in 1933, a huge forest fire called the Tillamook Burn destroyed the city's main timber supplies. Many Portland sawmills closed permanently after this fire, which swept across nearby Tillamook County.

In the 1930's, new dams on the Columbia and Willamette rivers provided cheap electricity for Portland. As a result, many industries that depended on electricity came to the city. They included metal processing and the manufacture of metal products. In the early 1940's, during World War II, shipbuilding and other war-related industries brought nearly 100,000 people to the city. Many of these people stayed after the war ended in 1945. In 1950, Portland had a population of 373,628.

By 1960, parts of central Portland had become rundown. Urban renewal projects during the 1960's replaced many old structures near the downtown area with apartment and office buildings. Portlanders also became concerned about pollution of the Willamette River. By 1972, efforts by industry and the federal, state, and city governments had made the Willamette in south Portland clean enough for swimming.

In 1972, air pollution and parking problems in the central business district of Portland led to adoption of the Downtown Program. A number of projects were carried out as part of the program to reduce congestion and preserve the downtown area. These projects included the construction of parking garages and the widening of some sidewalks. Another part of the program,

the Portland Transit Mall, was completed in 1977. This open mall serves as a center for the city's bus traffic. The Downtown Program also included the River Place residential and commercial development on the Willamette River, the Pioneer Place office and shopping mall in downtown Portland, and the Oregon Convention Center in southeast Portland.

The 11-mile (18-kilometer) Metropolitan Area Express (MAX) rail line, completed in 1986, links downtown Portland with the Oregon Convention Center and the suburb of Gresham. A second line linking downtown Portland with the western suburbs was completed in 1998.

Between 1950 and 1980, the population of Portland declined slightly, but the metropolitan area population increased. In the 1980's and 1990's, the city's population rose again, reaching 529,121 by 2000. The metropolitan area population continued to grow. Robert J. Caldwell

Portland cement. See **Cement and concrete.**

Porto, *PAWR too* (pop. 302,467), is Portugal's second largest city. Only Lisbon is larger. Porto is also called Oporto (pronounced *oh PAWR toh*). It is one of the country's chief seaports and serves as the commercial and industrial center of northern Portugal. It lies on the Douro River, 3 miles (5 kilometers) from the Atlantic Ocean. For location, see **Portugal** (political map). Porto is known for its role in processing and exporting Portugal's excellent port wines. The city also has food-processing plants, sugar refineries, textile mills, and other industries. Principal landmarks in Porto include the cathedral, which dates from the 1100's, and the bishop's palace, built during the 1700's. The Arrábida Bridge, one of three bridges across the Douro at Porto, is one of the longest concrete arch bridges in Europe. The University of Porto was founded in 1911.

Porto began as an ancient Roman trading community. During the 1700's, Porto's wine trade began to link the city closely with England. The struggle to establish a constitutional government for Portugal began in Porto in 1820. Douglas L. Wheeler

Pôrto Alegre, *PAWR too ah LEH grih* (pop. 1,386,828; met. area pop. 2,906,472), is the capital of the state of Rio Grande do Sul in Brazil. It is on the Guaiba River, at the head of the Patos Lagoon—an arm of the Atlantic Ocean (see **Brazil** [political map]). Its name means *Joyous Port.*

Pôrto Alegre is a major industrial and commercial center. A modern city, it has many skyscrapers. Its port can serve small ships. Meat, lumber, and tobacco from outlying rural areas are the city's chief exports. Pôrto Alegre's industries include brewing, tanning, meat packing, and wool processing. The city has many banks, other financial institutions, and universities.

Pôrto Alegre was founded in the 1740's by colonists from the Azores. In the 1800's, many German and Italian immigrants settled in the city. J. H. Galloway

Porto-Novo, *PAWR toh NOH voh* (pop. 144,000), is the official capital of Benin. However, most of the nation's government activity takes place in the nearby city of Cotonou. Porto-Novo lies in southeastern Benin on the lagoon of Porto-Novo, an inlet of the Gulf of Guinea in the Atlantic Ocean. For location, see **Benin** (map). Porto-Novo is a main trading center for goods produced in Benin. A railroad and Benin's chief river, the Ouémé, connect the city with the interior of the country.

Porto-Novo was probably founded in the 1600's by the Adja, a black African people. Later in the 1600's, the Portuguese founded a trading post in the city. Porto-Novo became a center of the slave trade in the 1770's. French colonial influence began in the mid-1800's. The city became a regional capital of French West Africa after that colony was established in 1904. When Benin gained independence from France in 1960, Porto-Novo became the capital. Immanuel Wallerstein

Porto Rico. See **Puerto Rico.**

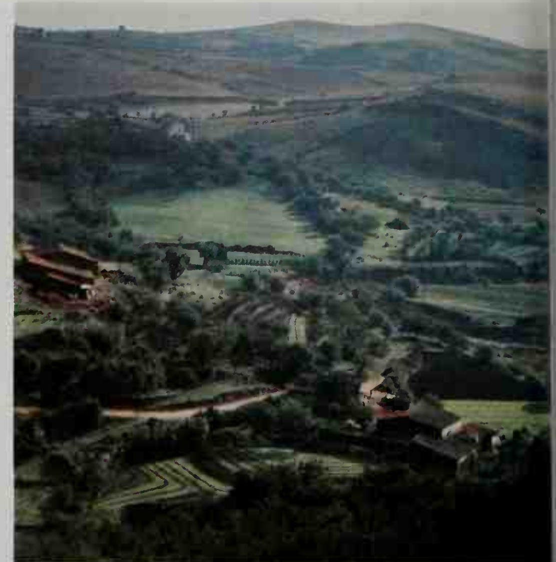
Portobelo, *PAWR toh BEHL oh* (pop. 2,774), a village on the Caribbean Coast of Panama, was often attacked by English pirates of the 1600's and 1700's. The town was one of the chief Spanish trading centers in Latin America. Spanish ships sailed from Portobelo to Spain with treasures of Latin America. The Spaniards founded the town in 1597. Portobelo lost importance as a seaport after the early 1700's. Gary Brana-Shute

Portsmouth, *PAWRTS muhth,* a city on the southern coast of England, is the United Kingdom's chief naval center. It is the chief city in the district of Portsmouth, which has a population of about 174,700. For location, see **England** (political map).

Harbor facilities, dry docks, and ship repair basins line much of the waterfront in Portsmouth. Among the city's major industries are shipbuilding, engineering, and the manufacture of clothing, plastics, and pharmaceuticals. Portsmouth's landmarks include a cathedral that dates from the 1100's and the birthplace of the famous novelist Charles Dickens.

Portsmouth was founded in the 1100's. It became the leading naval station in England after the construction of a dockyard there during the 1500's. The dockyard declined in size and use after World War II ended in 1945.
Peter R. Mounfield

Portsmouth, *PAWRTS muhth* (pop. 20,784), is the chief seaport on the coast of New Hampshire. It is a commercial center of southeastern New Hampshire. Portsmouth and Rochester, New Hampshire, form a metropolitan area with 240,698 people. Portsmouth was founded as Strawbery Banke in 1630 and was incorporated as a city in 1849. It lies at the mouth of the Piscataqua River (see **New Hampshire** [political map]). The Portsmouth Naval Shipyard is nearby. The city has a number of corporate offices and financial institutions. Its attractions include Strawbery Banke, a restored historic area, and many houses dating from the 1700's or early 1800's. The city has council-manager government.
Robert L. A. Adams



See also **New Hampshire** (picture: Strawbery Banke); **Portsmouth Naval Shipyard.**

Portsmouth Naval Shipyard, *PAWRTS muhth,* New Hampshire, occupies over 200 acres (81 hectares) on a group of connected islands in the Piscataqua River. The islands are within Maine, but the naval base uses nearby Portsmouth, New Hampshire, as its post office address. Commands at the base include a naval hospital, marine barracks, and naval disciplinary command.

Shipbuilding on the Piscataqua River dates from 1645, but the first ship built at the navy yard, established in 1800, was not launched until 1815. After World War I (1914-1918), the base specialized in submarine construction. W. W. Reid

Most of Portugal's people live in small fishing or farming villages. Here, a fishing crew braves the Atlantic Ocean.

Adeline Haaga, Tom Stack & Asso

Farmland, such as that seen here, covers much of the country. Portugal's crops include grapes, olives, and tomatoes. Wines made from Portuguese grapes are world famous.

Portugal

Portugal is the westernmost country of continental Europe. The small country lies on the Iberian Peninsula. Spain—Portugal's neighbor to the east and north—covers most of the peninsula. Western and southern Portugal face the Atlantic Ocean. Lisbon is Portugal's capital and largest city.

Most Portuguese live in rural villages. The villagers include skilled people who brave the rugged Atlantic waters to fish in small boats and farmers who grow grapes that are used to make fine wine. Fish and wine from Portugal are enjoyed by people in many parts of the world.

During the 1400's and 1500's, daring Portuguese explorers launched the great age of European exploration. Bartolomeu Dias commanded the first European voyage around the Cape of Good Hope at the southern tip of Africa. Vasco da Gama sailed around the cape and discovered a sea route to Asia. Pedro Álvares Cabral sailed to what is now Brazil. These expeditions and other voyages led to the establishment of a vast Portuguese empire. This empire included colonies in Africa, Asia, and South America.

Portugal's power and influence began to weaken during the late 1500's. But the country held on to much of its empire for more than 400 years. In the 1960's and 1970's, however, all but three of its remaining overseas territories gained their independence. These three territories were the Azores and the Madeiras, Portuguese islands in the North Atlantic Ocean; and Macao, a tiny area located on the southern coast of China. In 1999, Portugal returned control of Macao to the Chinese.

Douglas L. Wheeler, the contributor of this article, is Professor of Modern History at the University of New Hampshire and the author of books about Portugal and Angola.

The 1970's brought about a major political change within Portugal. Dictators had ruled the country from 1926 to 1974. During this period, personal freedom was limited and opposition to the Portuguese government was crushed. In 1974, a group of young military officers staged a revolution and overthrew the country's dictatorship. Portugal adopted a democratic system of government in 1976.

Government

Portugal is a republic. Its Constitution, adopted in 1976, grants the people such rights as freedom of speech, religion, and the press. Portuguese citizens 18 years or older may vote in elections.

Facts in brief

Capital: Lisbon.
Official language: Portuguese.
Official name: República Portuguesa (Portuguese Republic).
Area: 34,340 mi² (88,941 km²), not including the Azores and Madeira island groups. *Greatest distances*—north-south, 350 mi (563 km); east-west, 125 mi (201 km). *Coastline*—458 mi (737 km).
Elevation: *Highest*—Estrela, in Serra da Estrela, 6,539 ft (1,993 m). *Lowest*—sea level.
Population: *Estimated 2002 population*—9,863,000; density, 287 per mi² (111 per km²); distribution, 52 percent rural, 48 percent urban. *1991 census*—9,862,540. Population figures include the Azores and Madeira island groups.
Chief products: *Agriculture*—grapes, tomatoes, potatoes, hogs, chickens, milk, beef cattle, corn. *Fishing*—sardines, tuna. *Manufacturing*—textiles, food products, paper products, electrical machinery, cork products, ceramics, shoes, cement, fertilizer.
National anthem: "A Portuguesa" ("The Portuguese").
Money: *Basic unit*—euro. One hundred cents equal one euro. The escudo, the former basic unit, was taken out of circulation in 2002.

National government. A parliament called the Assembly of the Republic makes Portugal's laws. It has 230 members. The members of the Assembly are elected by the people and serve four-year terms.

The people elect a president to a five-year term. The president may serve no more than two consecutive terms in office.

The president appoints a prime minister. The prime minister heads the government. The person chosen by the president for the office is usually the leader of the political party that has the most seats in the parliament. The prime minister chooses members of a Cabinet. The prime minister and the Cabinet carry out the operations of the government.

Local government. Portugal—including the Azores and Madeiras—is divided into 22 districts for purposes of local government. Voters in each district elect a governor and legislature to run the district government. Cities and towns within the districts also have local governments.

Politics. Portugal has a large number of political parties. Among the largest and most powerful parties in the country are the Social Democratic Party and the Portuguese Socialist Party. Portugal's other important political parties include the People's Party and the Unified Democratic Coalition.

Courts. The Supreme Court of Portugal is the highest court of appeal in the country. Portugal also has four lower courts of appeal and a variety of district and local courts.

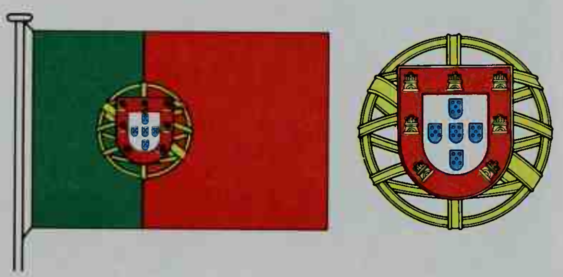
Armed forces. About 54,000 people serve in Portugal's armed forces. The country has an army, navy, and air force. The armed forces include both volunteers and draftees. People who have finished their terms in the active military remain in the military reserves until age 35. Portugal's military reserves have about 210,000 members.

People

Population and ancestry. Lisbon, Portugal's capital, is also the country's largest city. The city is also the country's economic, political, and cultural center. Lisbon has one of the world's finest natural harbors. Porto is the country's only other large city. Porto is the major economic center of northern Portugal. About a third of the Portuguese people live in or near Lisbon and Porto. See **Lisbon; Porto.**

People called Iberians were the first known inhabitants of what is now Portugal. They lived there before the beginning of recorded history—about 5,000 years ago. Through the centuries, various other groups came to Portugal. They included Phoenicians, Carthaginians, Celts, Greeks, Romans, Visigoths, and North African Muslims.

Today's Portuguese people are a mixture of all the country's groups. Since the mid-1960's, thousands of black Africans from Portugal's former African colonies have moved to Portugal. They form the country's only minority group.



Way of life. Most rural Portuguese live in small fishing or farming villages. Fishing villages line the country's coast. The people of these settlements have long relied on fishing for their livelihood. They brave the rugged waters of the Atlantic Ocean in small boats to catch fish. Family members who stay home do such chores as cleaning the fish and mending the nets.

Portuguese farmers raise a variety of crops, but they are best known for their fine grapes that are used to make wine. Wines from Portugal are enjoyed by people in many parts of the world. Some Portuguese winemakers still follow the colorful old custom of crushing the grapes with their bare feet.

Although Portugal remains a rural country, its cities—especially Lisbon and Porto—are growing rapidly. Each year, a large number of the nation's rural people move to urban areas to find jobs in industry or other city activities. Portugal's cities have buildings that are hundreds of years old as well as modern apartment and office buildings.

The Portuguese maintain close family ties. Often, two or more generations of a family live together in the same house. Men and women who move to cities from villages tend to keep in close touch with their relatives back home.

Most Portuguese in both cities and rural areas wear clothing similar to that worn in Europe and the United States. But some rural people dress in styles similar to those of their ancestors. Berets, stocking caps, and baggy shirts and trousers are common among men. Many

Portugal's flag, *left,* has a band of green, which stands for hope; and of red, which symbolizes the blood of the country's heroes. Portugal's coat of arms appears on the flag and at the right. It shows castles and shields that recall Portuguese history.

Portugal lies in southwestern Europe. The Azores and Madeiras, two island groups to the west, are Portuguese territories.

*Does not appear on map; key shows general location.
†Population is for the municipality, which may include rural areas as well as the urban center.
Source: 1994 official estimates.

women wear long dresses and shawls. In some places, the people dress entirely in black or another dark shade for everyday activities. But they put on brightly colored costumes for special occasions.

The chief foods of Portugal include beef, pork, chicken, fish (especially sardines), rice, and potatoes. A favorite dish is *bife com ovo a cavalo*—steak with French fried potatoes and an egg on top.

The people enjoy such recreational activities as folk songs, bullfights, and soccer. Portuguese bullfights differ from those of Spain and Latin America in a major way. In Spain and Latin America, the bulls are killed at the end of the bullfights. In Portugal, it is illegal to kill the bulls during the fights.

Language. Portuguese is the official, and the only widely used, language of Portugal. Like Spanish, it is one of the Romance languages that developed from Latin. Portuguese and Spanish are similar in many ways. See **Portuguese language**.

Religion. Most Portuguese who practice a religion are Roman Catholics. The country also has small groups of Jews, Muslims, and Protestants.

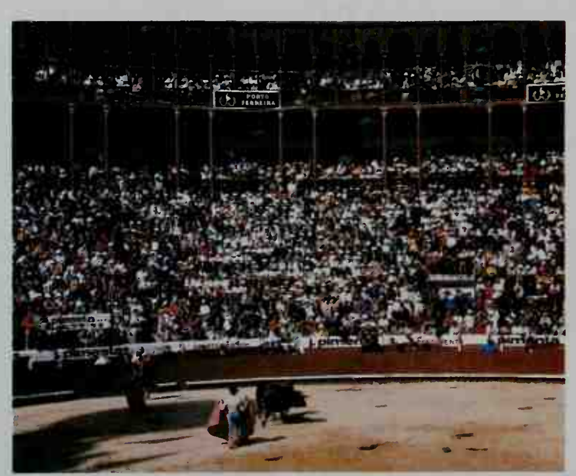
Until the early 1900's, the Roman Catholic Church was, in effect, part of Portugal's national government. The church and state were separated in 1911. But Catholicism remains important to the Portuguese, especially the rural people. In many rural areas, Catholic priests have major roles in local government, education, and social life. Traditional Catholic celebrations, processions, and pilgrimages are important activities for the people. Each year, thousands of people make a pilgrimage to the Portuguese town of Fátima. There, in 1917, the Virgin Mary reportedly appeared to three children who were tending sheep (see **Fátima, Our Lady of**).

Education. Portugal's educational system is weak compared to those of most other Western European nations. Many adults in rural areas cannot read or write. For Portugal's literacy rate, see **Literacy** (table: Literacy rates). By law, Portuguese children must attend school between the ages of 6 and 15. But many children leave school before 15. In most cases, they come from poor families and leave school to begin work. Elementary education is available throughout Portugal, but many parts of the country have no high schools.

Portugal has 20 universities, many of which were opened after the 1974 revolution. The largest one is Lisbon University.

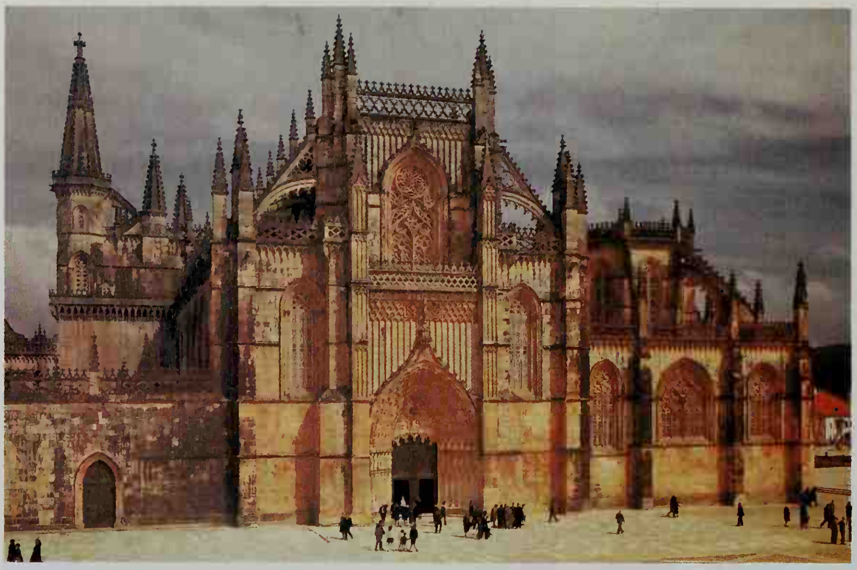
The arts. The golden age of Portuguese art began in the 1400's, about the same time that the country became a world power. It lasted until the 1600's. The art of the golden age was influenced by the Catholic Church, the royalty, and the Portuguese love of the sea.

During the golden age, architects built many beautiful churches and artists decorated them with religious paintings and sculptures. These architects and artists developed a striking style noted for its elaborate use of decoration. The style is called *Manueline,* after King Manuel I, who ruled from 1495 to 1521 and sponsored many artists. A famous example of Manueline art is a church window frame at Tomar, shaped to resemble such marine items as coral, seaweed, and ship nets and ropes. Nuno Gonçalves, the best-known artist of the golden age, gained fame for fine paintings of saints, kings, and princes.



Claus Meyer, Black Star

Lisbon is Portugal's capital and its largest city. This busy, crowded city on the west coast of Portugal serves as the nation's economic, political, and cultural center.



S. C. Bisserot, Bruce Coleman Inc.

An outdoor market in the small town of Loulé attracts shoppers seeking fresh fruits and vegetables. Many Portuguese farmers regularly sell crops at such markets.

J. Messerschmidt, Bruce Coleman Inc.

Bullfights attract huge crowds in Portugal. In Portuguese bullfights—unlike the bullfights of Spain and Latin America—it is illegal to kill the bull.

A Roman Catholic church i Batalha, *shown here,* is one o many magnificent churches built during the golden age o Portuguese art. Much Portuguese art and architecture during this period dealt with religious subjects.

Toni Schneiders, Bruce Coleman Inc.

The most famous literary work of the golden age was *Os Lusíadas* by Luiz de Camões. Published in 1572, this long epic poem praises Portugal's historical accomplishments and heroes.

After about 1800, religious art gave way to art that reflects everyday life. The Portuguese became known for their novels, poetry, and political cartoons. In 1998, Portuguese novelist Jose Saramago won the Nobel Prize for literature.

The Portuguese also have a wealth of folk art. Their folk songs range from lively dance music called *chulas* and *viras,* to *fados* (sad songs sung to the accompaniment of a guitar). Portuguese handmade pottery, lace, and linen are prized by people in many countries.

Land and climate

Portugal covers 34,340 square miles (88,941 square kilometers). This figure does not include the Azores or the Madeira Islands. The Azores cover 868 square miles (2,247 square kilometers), and the Madeiras cover 307 square miles (794 square kilometers). Most of Portugal is relatively flat and lies at a low altitude above sea level. But there are mountain ranges in northeastern, central, and southwestern Portugal.

Land regions. Portugal can be divided into four main land regions: (1) the Coastal Plains, (2) the Northern Tablelands, (3) the Central Range, and (4) the Southern Tablelands.

The Coastal Plains are flatlands that lie along and near the western and southern coasts. In some areas, the region is narrow, but in other places it extends into the center of the country. This region supports numerous farm and fishing villages. Portugal's main cities, Lisbon and Porto, lie on the Atlantic Coast in the region.

The Northern Tablelands, Central Range, and Southern Tablelands are extensions of the *Meseta,* a huge plateau that covers most of Spain. The regions consist mainly of plains broken by mountain ranges. Farmers grow crops and raise livestock on the plains. The mountains yield a high percentage of Portugal's minerals.

Portugal's highest mountains are in the Serra da Estrela range in the Central Range region. Peaks there rise more than 6,000 feet (1,829 meters) above sea level. Estrela, Portugal's highest mountain, rises 6,539 feet (1,993 meters) in the region.

Rivers. Two major rivers, the Douro and the Tagus, cross Portugal from east to west. The Douro, in the north, empties into the Atlantic Ocean at Porto. The Tagus, in the center of the country, flows into the ocean at Lisbon. The Guadiana, another important river, forms part of Portugal's boundary with Spain in the southeast.

The Tagus River divides Portugal in several ways. The area north of the river is much cooler than the area south of it. The northern area is heavily populated, while the south is thinly settled. Farms in the north tend to be small, but the south has many huge farms. In addition, the people north of the Tagus are generally more conservative politically than those south of the river. See Tagus River.

Climate. Portugal has a mild climate. The country receives much sunshine, especially in the south. Vacationers flock to resorts in the south to enjoy the warm, sunny climate there. In spring and summer, Portugal's weather is generally warm and dry, with little or no rain. In fall and winter, the weather is cool and heavy rains fall on much of the country. Southern Portugal receives no snow, but parts of the north receive a little. Snow generally covers the highest peaks of the Serra da Estrela range for several months each year.

Average temperatures in Portugal range from about 70 °F (21 °C) in July to about 50 °F (10 °C) in January. Average annual precipitation totals about 55 inches (140 centimeters) in parts of the inland north, but only about 20 inches (51 centimeters) in the coastal south.

Economy

Portugal ranks as one of the poorest countries in Europe. Since the 1960's, however, the country has generally experienced economic growth.

Until the mid-1900's, Portugal's economy was based

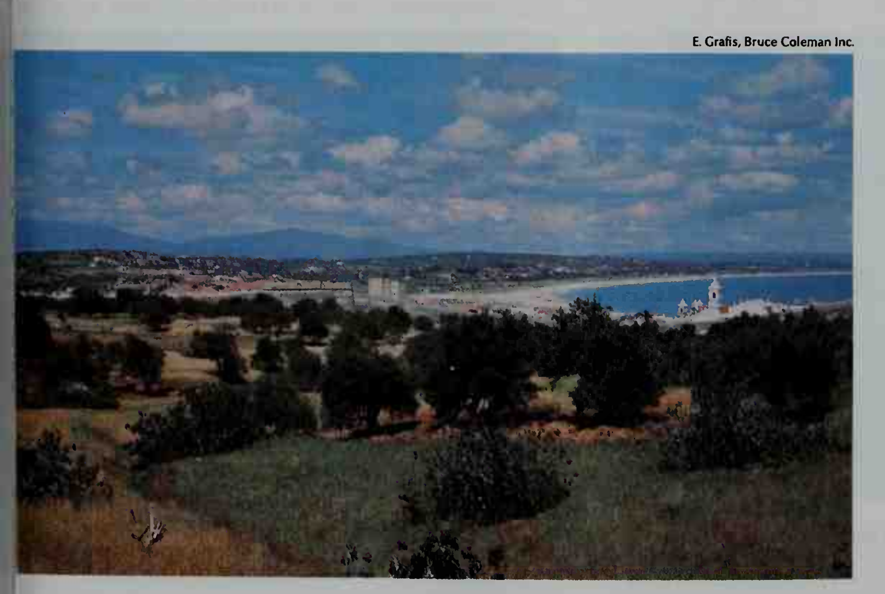
chiefly on agriculture and fishing. Today, manufacturing is the most important single element in the economy. It accounts for about 30 per cent of Portugal's economic production. Agriculture and fishing together account for about 10 per cent. Service industries, taken together, account for about 60 per cent of the economic production.

Natural resources. Portugal has some valuable mineral resources, but—for the most part—these resources have not been well developed. The most important developed mineral resource is building stone, which is found throughout the country. Decorative marble is the most valuable type of building stone quarried in Portugal. Portugal also has deposits of coal, copper, and wolframite. Wolframite is used to make tungsten.

Forests cover about a third of Portugal. Large pine forests stand in the north. Forests of cork oak trees in central and southern Portugal yield large quantities of cork.



Portugal's rivers, especially the Douro and Tagus, provide hydroelectric power. The Atlantic Ocean is another important resource. Many Portuguese have long depended on its fish for their livelihoods.

Service industries. Government and trade are the most important service activities in Portugal. The federal government heavily controls several industries, including banks, mineral processors, and utilities. Portugal's retail trade establishments benefit from the large numbers of tourists that visit the country. Other service industries include education and health care.

Manufacturing. The production of textiles is the leading manufacturing activity in Portugal. Cotton fabric is the most important type of textile produced in the country. Other leading manufactured goods include food products, paper products, and electrical machinery. Portugal's food-processing activities include meat packing and the production of animal feed, canned sardines, and wine. Portuguese factories also produce cement, ceramics, cork products, shoes, and fertilizer.

Agriculture and fishing. Wine grapes are grown in the river valleys that cut across Portugal. The vineyards of the Douro Valley yield grapes for port wine, which is

E. Grafis, Bruce Coleman Inc.

Flat plains cover much of Portugal. In southwestern Portugal, *left,* the Coastal Plains rise to meet the mountains of the Southern Tablelands.

named for the city of Porto. Grapes from the Madeiras are used for Madeira wine. Other crops grown in Portugal include almonds, corn, olives, potatoes, rice, tomatoes, and wheat. Farmers also raise cattle, chickens, hogs, and sheep. Fishing crews catch cod, sardines, tuna, and many other kinds of fish.

Most crop farms in Portugal are small. The majority of the farmers own the land they work. But some farms, especially in the south, are state-owned collective farms. Large numbers of Portuguese farmers still use old-fashioned methods and equipment, but the use of modern farm methods and equipment is increasing.

Foreign trade. Portugal's major exports include clothing and textiles, cork, paper, and wine. The country imports large amounts of chemicals, grain, iron and steel, petroleum and petroleum products, textile yarn and fiber, and transportation equipment.

From 1960 to 1986, Portugal was a member of the European Free Trade Association (EFTA), an economic organization of nations. In 1986, Portugal left EFTA and joined the European Community (EC), a larger European economic organization of nations. In 1993, Portugal and the other EC countries formed the European Union, which works for both economic and political cooperation among its member nations. At that time, the EC became part of the European Union.

Germany, a member of the European Union, is Portugal's chief trading partner. Portugal also trades heavily with other European Union members, including France, Italy, Spain, the United Kingdom, and with some other European countries. It also trades heavily with the United States.

Transportation. A railroad network connects most of Portugal. The national government owns and operates the main railroad system. The government also owns and operates the national airline, Air Portugal. Lisbon Airport is Portugal's main international airport. Lisbon is the country's chief port.

Portugal has an average of about 1 automobile for every 7 people. In cities, automobiles, buses, and electric streetcars provide much of the transportation. In rural areas, some people still travel by old means, such as oxcart, horse, or mule.

Communication. The national government owns and operates Portugal's telephone, telegraph, and postal systems. Portugal has an average of about 1 radio for every 4 people and about 1 television set for every 5 people. Portugal has about 25 daily newspapers, including *Correio da Manhã* of Lisbon and *Jornal de Notícias* of Porto.

History

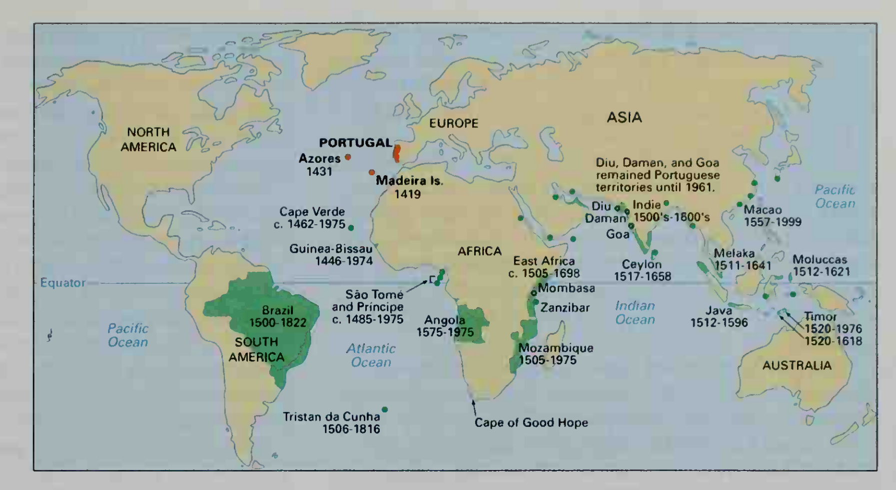
Early days. Prehistoric people probably lived in what is now Portugal over 100,000 years ago. The first known inhabitants of the area were called Iberians. These people lived on the Iberian Peninsula—in present-day Portugal and Spain—at least 5,000 years ago.

A number of groups invaded the Iberian Peninsula during early times. Phoenicians from the eastern shore of the Mediterranean Sea established settlements there in the 1000's B.C. Celts, from northern Europe, settled in the area during the 900's B.C., and Greeks arrived in the 600's. Invaders from the powerful North African city of Carthage took control of much of the Iberian Peninsula in the 400's B.C.

Roman rule. In 201 B.C., the mighty Roman Empire defeated Carthage in the Second Punic War (see **Punic Wars**). As part of the peace settlement, Rome gained the right to the Iberian Peninsula. Little by little, the Romans conquered the peoples on the peninsula. They completed their conquest of what is now Portugal by about the time of Christ.

The Romans did much to build up the area that is now Portugal. They established cities and a network of roads there. Latin, the language used by the Romans, became the basis of the Portuguese language. The Roman Empire adopted Christianity as its official religion in the late A.D. 300's. Under Roman rule, Portugal began developing into a Christian land.

The Romans called the Portuguese portion of the Iberian Peninsula *Lusitania.* They named the port and city at present-day Porto *Portus Cale.* These words were the origin of the name *Portugal.*



S. C. Bisserot, Bruce Coleman Inc.

Wine made from grapes has long been a leading product of Portugal. A laborer shovels a huge pile of grapes, *above.* The grapes will later be crushed, and wine made from their juice.

Jean Claude Seine, DPI

Producing metals and machinery is one of Portugal's major manufacturing activities. A worker in a Lisbon factory, *above,* cuts a large sheet of metal to a specified size and shape.

Portugal's empire in the mid-1500's, at the height of the nation's power, included colonies in many parts of the world. This map shows these colonial possessions and when Portugal ruled them.

WORLD BOOK map

Visigoths and Muslims. Germanic tribes swept across the West Roman Empire in the A.D. 400's, and helped bring about its collapse in 476. The Visigoths, one of the tribes, conquered the Iberian Peninsula. The Visigoths were Christians, and Portugal remained a Christian land under their rule.

In the early 700's, North African *Muslims* (followers of the Islamic religion) conquered most of what are now Portugal and Spain. They constructed Arab-style buildings, introduced new crops, and improved education and the system of roads.

Many Christians of the Iberian Peninsula opposed Muslim rule. Christian opposition was especially strong in the north. The Christians struggled to retake their land for hundreds of years. In the 1000's, they gained the upper hand. By the mid-1200's, the Christians had driven the Muslims from Portugal and from most of Spain.

Founding the Portuguese nation. Henry of Burgundy, a French nobleman, had joined the Iberian Christians in their fight against the Muslims. In 1094, Alfonso VI, a Christian king of Spain, rewarded Henry with the counties of Porto and Coimbra, in what is now northern Portugal. Alfonso named Henry the Count of Portugal. Portugal was then considered a part of Spain.

Henry of Burgundy's son, Afonso Henriques, won many victories over the Muslims. In 1143, he took the title of king of Portugal, and established Portugal as a kingdom independent from Spain.

In 1385, a new royal line, the House of Aviz, came to the Portuguese throne. King John I became the first Aviz king. His armies defeated Spanish forces and helped guarantee the future independence of Portugal from its powerful neighbor to the east. King John also made an alliance with England. This alliance, still in force, is the oldest existing political alliance in Europe.

The age of exploration. Even before the 1400's, Portuguese traders and fishing crews had sailed far from home into the Atlantic Ocean. By 1400, the Portuguese had gained much knowledge about the sea. They had also mastered navigational skills and the ability to build ships capable of making long voyages.

Henry the Navigator, a son of King John I, was a leading figure in Portugal's rise as a sea power. He never went on a voyage of exploration himself. But his studies contributed much to Portuguese marine skills, and he encouraged and sponsored many explorations.

Portuguese ships reached the Madeira Islands in 1419 and the Azores in 1431. By the time of Henry's death in 1460, the Portuguese had explored the west coast of Africa as far south as what is now Sierra Leone. In 1488, a Portuguese vessel commanded by Bartolomeu Dias sailed all the way around the Cape of Good Hope at the southern tip of Africa. The voyage marked the first time Europeans had rounded the cape.

Manuel I, called Manuel the Fortunate, became king of Portugal in 1495. Determined to increase his country's power and importance, he decided to sponsor a daring voyage around southern Africa to Asia. Vasco da Gama undertook this task in 1497. He led four ships around the Cape of Good Hope, and he reached India in 1498. Manuel soon sent Pedro Álvares Cabral to follow Da Gama's route, but Cabral drifted off course. In 1500, his fleet reached the east coast of what is now Brazil. The Portuguese also reached the coasts of Africa, the Arabian and Malay peninsulas, the East Indies, and Asia.

Empire and wealth. Settlers and soldiers followed closely behind the Portuguese explorers, establishing

1580 Spain invaded and conquered Portugal.
1640 Portugal regained its independence.
1822 Portugal lost its colony of Brazil.
1910 The Portuguese established a republic.
1928 António de Oliveira Salazar, who ruled as a dictator for 40 years, began his rise to power.
1949 Portugal and 11 other nations formed a military alliance, the North Atlantic Treaty Organization (NATO).
1960's Rebellions against Portuguese rule broke out in the country's African colonies.
1974 A revolution overthrew the Portuguese dictatorship.
1975 Almost all remaining Portuguese colonies gained independence.
1976 Portugal held its first free general elections in more than 50 years.
1986 Portugal joined the European Community, an organization that later became the basis of the European Union.

colonies. By the mid-1500's, Portugal controlled a vast overseas empire that included colonies in what are now the African countries of Angola, Cape Verde, Guinea-Bissau, Mozambique, and São Tomé and Príncipe; and in Brazil, Malaysia, Indonesia, and China.

Portugal gained great wealth from the resources of its colonies. It profited from the spice trade in Asia. It got gold from Africa and also took part in the slave trade there. Brazil yielded such valuable items as diamonds and gold. The empire also gave Portugal vast amounts of new land. Portuguese planters in Brazil, Africa, and elsewhere raised crops that contributed to the country's economy.

Years of decline. Portugal held on to much of its empire well into the 1900's. However, the country declined as an economic and world power much earlier.

As far back as the late 1500's, there were signs that Portugal had overextended itself. The small nation found that it had too few ships, settlers, soldiers, and sailors to manage and defend its vast empire well. In the 1600's, rival European states, including England, the Netherlands, and France, began to take over parts of the empire.

Internal policies and the effects of the Inquisition also contributed to Portugal's decline. Its kings had gained enormous power, and they ruled the people with strict measures. The Inquisition was an effort by the Roman Catholic Church to end *heresy* (opposition to its teachings). It further hurt the country's cultural and economic development. Many Portuguese Christians and Jews were killed or imprisoned during the Inquisition, and thousands of Jews were expelled from the country.

Spanish conquest. Spain invaded and conquered Portugal in 1580 and ruled the country for 60 years. In 1640, John, Duke of Braganza, led a rebellion that drove out the Spaniards and restored Portugal's independence. John became the first king of the House of Braganza, the last Portuguese line of monarchs. He took the title of John IV.

A brief revival. Portugal entered a period of economic revival about 1660. Revenue from Brazil's gold, diamonds, and farm products contributed greatly to the upsurge. A trade agreement made with England in 1703 also aided Portugal. Called the Methuen Treaty, it ensured steady trade between the two countries that benefited both.

England, which joined Scotland and Wales to form the United Kingdom in 1707, also helped Portugal maintain its status as an independent nation. Spain sought to regain control of Portugal, but England—an enemy of Spain—pledged aid to Portugal against foreign invaders. Between 1703 and the mid-1800's, the British acted several times to defend Portugal from invasion or threats by Spain or Spain's allies.

In 1807, French forces under Napoleon I invaded and conquered Portugal. But the British raised an army under Arthur Wellesley, later the Duke of Wellington, that finally drove the French forces from Portugal in 1811. The brief period of French rule marked the last time Portugal was controlled by outsiders.

A weakening monarchy. King John VI of Portugal fled to Brazil during the French occupation. He returned to Portugal in 1821. By that time, a spirit of political reform had grown strong in Europe. Many Portuguese demanded a more representative government and a limit to the power of the king. Portuguese army officers had revolted in 1820. In 1821, John VI agreed to a constitution that provided for some representative government.

In 1822, the Portuguese empire suffered a major blow. Brazil, the wealthiest part of the empire, declared its independence. See Brazil (History).

The first Portuguese republic. For many years, Portugal made little actual progress toward true representative government. The monarchy remained strong and the people had little voice in government. Opposition to the government grew steadily. In 1908, King Carlos I and his eldest son were assassinated in Lisbon by revolutionaries who wanted to end the monarchy's power. The king's young son, Manuel II, then came to the throne, but revolutionaries overthrew him in 1910 and established Portugal as a republic.

Portugal's first attempt at parliamentary democracy was a failure. It was marked by excessive government interference in society and political instability. In 15 years, the country had 45 different governments. The republic's leaders faced labor unrest and revolts by the military and civilians. Portugal fought on the side of the Allies during World War I (1914-1918), and the war costs weakened its already shaky economy.

The Salazar dictatorship. In 1926, army officers overthrew Portugal's civilian government. They abolished parliament, suspended civil rights, and set up a dictatorship. The officers were unable to solve the country's economic problems. In 1928, they chose António de Oliveira Salazar, an economics expert, to serve as minister of finance. But Salazar's role soon extended far beyond financial matters. Salazar soon took control of the government and began to rule as a dictator. He was named prime minister in 1932.

Salazar's government was a *right-wing* (conservative) dictatorship. It allowed the people few rights, and it included a secret police organization that crushed all opposition. Salazar's economic policies favored the wealthy, and poverty spread during his dictatorship.

In the mid-1900's, most European nations began granting independence to colonies they still held. But Salazar refused to give up Portugal's remaining colonies in spite of demands from the colonies and the United Nations. Salazar stressed the unity of Portugal and its colonies, which, after 1951, were called overseas provinces.

In 1961, Indian troops forced Portugal to give up its last colonial holdings in India. At about the same time, rebels in Portugal's black African colonies of Angola, Mozambique, and Portuguese Guinea (now Guinea-Bissau) began armed struggles against their Portuguese rulers. Portugal sent troops to fight the rebels. Thousands of people on both sides were killed, and the cost of the fighting further weakened Portugal's economy.

Salazar suffered a stroke in 1968, ending his long public career. He died two years later. Marcello Caetano replaced him as Portugal's ruler in 1968. Caetano took steps to reduce the harsh rule of the dictatorship, but not enough to suit many Portuguese.

The 1974 revolution. Military officers overthrew the dictatorship in 1974. They called their revolution the *Armed Forces Movement.* The movement abolished the secret police, restored rights to the people, and established a provisional government to run the country.

As part of the reforms, political parties were permit-

ted in Portugal for the first time since the 1930's. Communists, Socialists, and parties that favored free enterprise sought to control the new government. In 1974 and 1975, violence broke out between Portuguese people of differing political views.

End of the empire. Portugal's new government promised to end the country's control of its colonies. The African land of Portuguese Guinea gained independence as Guinea-Bissau in 1974. Angola, Cape Verde, Mozambique, and São Tomé and Príncipe—also in Africa—all gained independence from Portugal in 1975. In 1976, Portugal's colony of Portuguese Timor in the East Indies was taken over by Indonesia.

Shortly after these changes, Portugal began the process of returning the territory of Macao to China. Macao officially returned to China in 1999. Portugal now rules only its mainland territory and the Azores and Madeira Islands.

Political changes. In April 1975, Portugal held elections for the Constituent Assembly, a group chosen to write a constitution for the country. In April 1976, the new constitution took effect and established Portugal as a parliamentary democracy. Later that same month, the voters elected a president and members of the Assembly of the Republic, the country's new parliament. The Portuguese military kept an advisory role until 1982.

Between 1976 and 1985, control of Portugal's government changed hands a number of times. In 1985, the conservative Social Democratic Party gained control of the government. It held power for the next 10 years and brought a degree of political stability to the country.

Portugal experienced economic growth in the last half of the 1900's, but it also faced economic problems. Its costly wars in Africa and the internal violence that followed the 1974 revolution helped bring the economy to a state of near-collapse temporarily. After the revolution, there were periodic problems of inflation and high unemployment. But Portugal shared in the general European prosperity of the 1990's.

Recent developments. In 1995, Portugal's liberal Socialist Party gained the largest number of seats in the Assembly, and the head of the party became prime minister. The Socialist candidate for president, Jorge Sampaio, was elected in 1996 and reelected in 2001. In elections in 2002, the Social Democrats, a more conservative party, won the most seats in the Assembly.

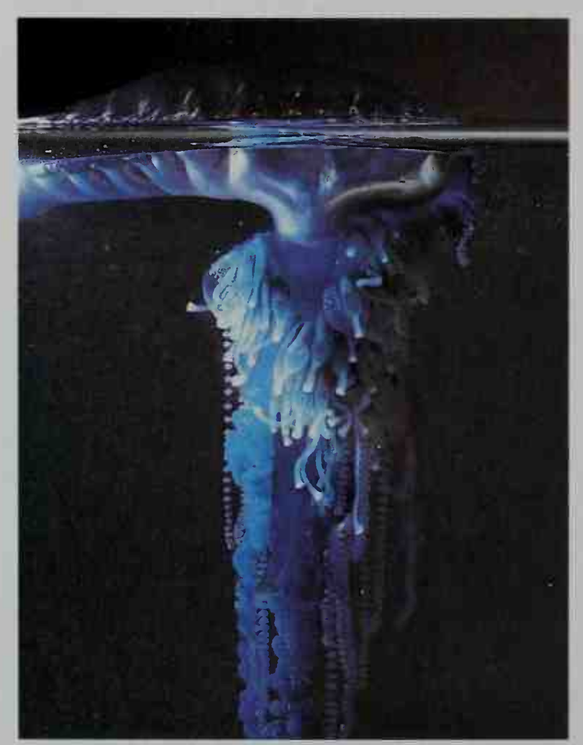
Portuguese language is the official language of Portugal, Brazil, Mozambique, and Angola. The language is also spoken by about 300,000 people in the United States. About 2 million people in northwestern Spain speak a Portuguese dialect called *Galego* or *Galician.* There are four principal dialects of Portuguese spoken today. The *Northern, Central,* and *Southern* dialects are used in Portugal, and the *Brasileiro* dialect is spoken in Brazil. Portuguese is a Romance language similar to Spanish (see **Romance languages**).

Portuguese and Spanish were essentially the same language until about A.D. 1143, when Portugal broke away from Spanish control. As Portuguese evolved, it developed distinctive phonetic and grammatical characteristics. Portuguese colonizers carried the language to Brazil during the 1500's. The Brazilians added words from the Tupi Indians and from African slaves. Brazilian Portuguese came to have the same relation to the language that American English has to British English.

Since the early 1900's, many persons in Portugal and Brazil have wanted to simplify and standardize Portuguese spelling. Scholars wished to take out many double consonants and other old-fashioned letter combinations. In 1943, the governments of Portugal and Brazil approved a new system, in which *f* is substituted for *ph*, *t* for *th*, and *i* for *y*. Richard P. Kinkade



See also **Spanish language** (Development).

Portuguese man-of-war is a floating creature found in warm oceans throughout the world. Although it resembles a jellyfish, it actually consists of a colony of hundreds of members.

The colony begins with just one *larval member*. As it grows, this original member produces new organisms of several different types, by a process called *budding* (see **Reproduction** [Through asexual reproduction]). The original member develops into a blue, balloonlike *float* that is filled with gas. This structure keeps the colony afloat. It also acts as a sail, catching the wind and moving the colony about.

The other members of the colony hang from the float. Stringlike members called *tentacles* catch food. When touched, the tentacles discharge poison that paralyzes and kills fish. The tentacles then haul the prey up to tube-shaped members that digest food for the entire colony. Other members produce the eggs and sperm necessary for reproducing new colonies.

A large Portuguese man-of-war may have a float 10 inches (25 centimeters) long and tentacles 30 feet (9 meters) long. The Portuguese man-of-war was probably named by sailors, who thought the animal's float resembled a type of sailing ship that was called a *man-of-war*.

Maira & Rod Borland, Bruce Coleman Inc.

The Portuguese man-of-war floats on the surface of warm oceans. It catches food with its submerged poisonous tentacles.

The Portuguese man-of-war often stings swimmers. Although it is rarely fatal, the sting causes a severe skin rash, extreme pain, nausea, and breathing difficulties. A Portuguese man-of-war washed up on the beach remains dangerous and should not be touched.

Scientific classification. The Portuguese man-of-war belongs to the phylum Cnidaria. Its scientific name is *Physalia physalis*. G. O. Mackie

Portuguese water dog is a breed of dog noted for its exceptional swimming ability. Portuguese water dogs can swim as far as 5 miles (8 kilometers) and dive to depths of 12 feet (3.7 meters). For hundreds of years, the Portuguese have used these dogs in fishing to pull fish and nets from the ocean. The dogs have also served as messengers between ships.

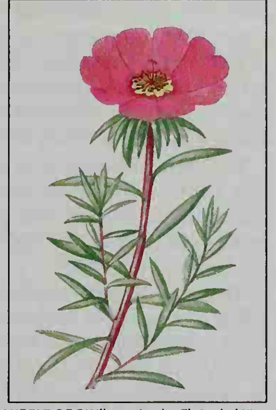
Portuguese Water Dog Club of America, Inc.

The Portuguese water dog is a strong swimmer. For hundreds of years, it has served as a working companion to Portuguese fishing crews, who have used it to pull in fish and nets.

The origins of the Portuguese water dog are uncertain. According to one theory, Portuguese water dogs descended from sheepdogs in southern Russia. Migrating tribes brought the sheepdogs to northwestern Africa by the 700's. From there, Moor invaders carried the dogs to Portugal, where they were bred to become water dogs.

Portuguese water dogs are muscular and have webbed feet and a tail that curls over the back. The webbed feet enable the dogs to tread water, and the tail serves as a rudder while swimming. Males stand 20 to 23 inches (51 to 59 centimeters) tall at the shoulder and weigh 42 to 60 pounds (19 to 27 kilograms). Females are slightly smaller. The dog's coat may be long and wavy or short and curly. The most common colors are black and white, and brown and white. Joan McDonald Brearley

Portuguese West Africa. See **Angola** (History).

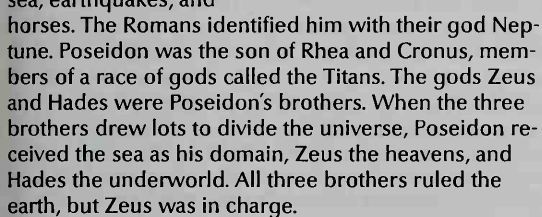


Portulaca, *PAWR chuh LAK uh,* is the name of a group of herbs with dainty red, yellow, pink, white, or purple flowers. The *rose moss* of Brazil, grown as a garden flower, grows flat or as tall as 1 foot (30 centimeters). It has narrow, fleshy leaves about 1 inch (2.5 centimeters) long. The *kitchen-garden portulaca* grows to $1\frac{1}{2}$ feet (46 centimeters) tall, with bright yellow flowers about $\frac{1}{2}$ inch (13 millimeters) wide, and broad leaves.

Portulacas make beautiful plants for a border or a

rock garden. They grow best in a sunny location in poor, rather light soil. The flowers open only in full sun. Several species make charming potted plants. But they are not satisfactory as cut flowers.

Robert A. Kennedy



Scientific classification. Portulacas belong to the purslane family, Portulacaceae. The scientific name for rose moss is *Portulaca grandiflora.* The kitchen-garden portulaca is *P. oleracea.*

WORLD BOOK illustration by Christabel King

Portulaca

Poseidon, *puh SY duhn,* was the Greek god of the sea, earthquakes, and horses. The Romans identified him with their god Neptune. Poseidon was the son of Rhea and Cronus, members of a race of gods called the Titans. The gods Zeus and Hades were Poseidon's brothers. When the three brothers drew lots to divide the universe, Poseidon received the sea as his domain, Zeus the heavens, and Hades the underworld. All three brothers ruled the earth, but Zeus was in charge.

Poseidon's wife was the sea goddess Amphitrite. They had two daughters and a son, the sea god Triton. Poseidon's offspring from countless love affairs included the magical horses Pegasus and Arion and the giants Antaeus and the one-eyed Polyphemus. In the epic poem the *Odyssey,* Poseidon hated the Greek hero Odysseus (Ulysses in Latin) for blinding Polyphemus. In some myths, Poseidon was also the father of the mortal hero Theseus.

Poseidon's attendants were the sea gods Phorcys, Proteus, and Nereus, and sea nymphs called *Nereids.* Like other sea deities, Poseidon often changed his shape. He drove a horse-drawn chariot and carried a three-pronged spear called a *trident.* Nancy Felson

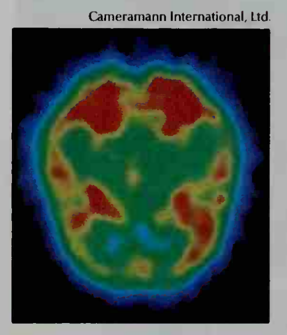
Positive number. See **Algebra** (Positive and negative numbers).

Positivism is a variation of the philosophical theory called *empiricism.* This theory states that all knowledge is based on experience. There are two forms of positivism. Auguste Comte, a French philosopher, developed the first form of positivism in the 1800's. The second form, known as *logical positivism,* originated during the 1920's in a group of philosophers called the Vienna Circle.

Comte's positivism is based on his three-stage evolutionary account of history. According to Comte, human thought goes through three stages: (1) theological, (2) metaphysical, and (3) positive or scientific. In the theological stage, people explain existence in terms of the actions of divine beings. In the metaphysical stage, explanations are sought in terms of basic causes and principles. In the positive stage, people use the *positive method* to explain existence. This method consists of reasoning by reference to observation alone.



Comte urged that the positive method be used for all scientific study, including the study of humanity. He argued that humanity should be studied through biology and *sociology,* a term he originated. Comte taught that progress should aim for *sociocracy,* a social state based on science and a new *religion of humanity.* Philosophers would govern this state according to the principles of positivism. See **Comte, Auguste.**

Logical positivism was developed by the Vienna Circle under the leadership of the German physicist and philosopher Moritz Schlick. The group included the German philosopher Rudolf Carnap and several other leading philosophers and scientists. Its main doctrine was a controversial idea called the *verifiability criterion of meaning.* According to this doctrine, all statements that cannot be verified by sense perception—except for provable statements of mathematics or logic—are meaningless nonsense. The Vienna Circle aimed to eliminate such unverifiable statements and ideas from science and philosophy. W. W. Bartley III

Positron emission tomography (PET), *tuh MAHG ruh fee,* is a technique used to produce images of the chemical activity of the brain and other body tissues. PET enables scientists to observe chemical changes in specific regions of a person's brain while the person performs various tasks, such as listening, thinking, or moving an arm or leg. Scientists use PET to com-

Cameramann International, Ltd.

Cameramann International, Ltd.

A PET scan produces images of the brain's chemical activity. The patient's head is placed inside a ring of sensors, which pick up gamma ray signals from the brain. A computer processes these signals to form a cross-sectional color image, *left.* The colors show the rate of activity in specific brain regions. Red indicates a high rate of activity.

pare the brain processes of healthy people and people with diseases of the brain. Research is being done to see if it is possible to use these comparisons to identify abnormalities that underlie various brain disorders. These disorders include such mental illnesses as bipolar disorder and schizophrenia, as well as such conditions as Alzheimer's disease, cerebral palsy, epilepsy, and stroke. PET also helps doctors diagnose certain other disorders, including heart disease and cancer.

In a PET scan of the brain, the patient's head is positioned inside a ring of cameralike sensors. These sensors can detect *gamma rays* (short-wave electromagnetic radiation) from many angles. A solution containing glucose bound to a harmless amount of a radioactive substance is injected into a vein. This radioactive *labeled glucose* mixes with the glucose in blood and soon enters the brain.

The radioactive substance gives off *positrons,* particles identical to electrons but carrying an opposite electric charge. The positrons collide with electrons present in brain tissue and gamma rays are *emitted* (given off). The sensors record the points where these rays emerge. A computer then assembles these points into a three-dimensional representation of the emitting regions. This representation is displayed on a video screen as cross-sectional "slices" through the brain.

Colors in a PET image show the rate at which specific brain structures consume the glucose. The rate of glucose consumption indicates how active these structures are during a particular task. For example, if the person having the PET scan looks at an object, the brain region that receives and interprets visual signals will appear red on the screen. Red indicates the highest rate of activity. Other colors that appear in PET images include orange—the next highest rate of activity—yellow, green, and blue, the lowest rate. Michael E. Phelps

Possession. See Exorcism.

Possessive case. See Case.

Possum is a type of furry mammal that lives in the trees of Australia, New Guinea, and nearby islands. Possums are *marsupials*—that is, the females give birth to young that complete their development while attached to the mother's nipples. Like most marsupials, young possums develop while carried about in a pouch on their mother's abdomen. Both possums and opossums are marsupials, but they are not closely related.

Possums move about at night and sleep during the day. They have handlike hind feet that help them grasp the branches of trees. Possums eat mainly blossoms, fruits, insects, and sap. The animals have black, brown, gray, tan, or white fur.

There are about 40 species of possums. The *brush-tailed possum* lives in Australian cities and raids fruit trees and garbage cans for food. Brush-tailed possums weigh from 3 to 11 pounds (1.4 to 5 kilograms). Other large species of possums, called *cuscuses,* weigh as much as 8 pounds (3.4 kilograms). The mouse-sized *honey possum* has a long, tube-shaped mouth and feeds on nectar and pollen. *Pygmy possums* weigh as little as $\frac{1}{2}$ ounce (14 grams). Several species of possums, called *gliders,* have large folds of skin between the front and rear legs on each side of the body. When the legs are spread, this skin serves as wings for gliding.

Scientific classification. The brush-tailed possum and cuscuses belong to the family Phalangeridae. The honey possum makes up the family Tarsipedidae. Pygmy possums belong to the family Burramyidae. Most gliders are in the family Petauridae. Michael L. Augee

A possum feeds on the yellow blossoms of a tree, *above.* Possums sleep during the day and are active at night.

Post, Emily Price (1873?-1960), made a career out of good manners. Her book *Etiquette* tells people how to behave properly in all types of social situations. After its publication in 1922, Post became established as an authority on proper behavior. She emphasized that good manners are based on common sense and a regard for the feelings of others. She revised her book frequently to take into account changing social conditions and new patterns of social behavior.

Post was born in Baltimore, Md., the daughter of a wealthy architect. Her first book, *The Flight of the Moth* (1904), was a fictional story of life among socially gracious people in the early 1900's. Her other books include *How to Behave Though a Debutante* (1928), *The Personality of a House* (1930), *Children Are People* (1940), and *Motor Manners* (1950). She also wrote newspaper columns and made radio broadcasts. Letitia Baldrige

Post, Wiley (1899-1935), a pioneer American aviator, was the first person to make a solo flight around the world. He made the historic flight in 1933 in a single-engine Lockheed Vega nicknamed *Winnie Mae,* covering 15,596 miles (25,099 kilometers) in 7 days 18 hours 49 minutes. Post used a new automatic pilot system that steered the plane while he rested. Two years earlier, Post and navigator Harold Gatty had flown the *Winnie Mae* around the world in a record 8 days 15 hours 51 minutes.

United Press Int.

Wiley Post

Post was born in Van Zandt County, Texas. He learned to fly in the 1920's and bought his first plane

in 1926. Post flew in a number of speed events, winning the National Air Race of 1930.

Post later advanced high-altitude flight by helping design a rubber suit that allowed him to operate in low air pressures at more than 30,000 feet (9,000 meters). Post died in a plane crash in Alaska with his friend the cowboy-humorist Will Rogers. Roger E. Bilstein

Post exchange is a store or shop that the United States Department of Defense operates for active-duty and retired military personnel, and their families. The Army and Marine Corps usually call it a *PX.* The other services usually refer to it as a *base exchange.* On board vessels, the exchange is called a *ship's store.* Major post exchanges resemble department stores. They sell a wide range of goods, from such personal items as toilet articles to automobile parts and home appliances. Many have beauty and barber shops. Joel Slackman

Postage stamp. See Postal Service, United States (Post office services); Stamp; Stamp collecting.

Postal Service, United States, is an independent establishment within the executive branch of the United States government. It provides mail services, including pickup and delivery, and sells postage stamps and postal money orders. The Postal Service is one of the world's largest organizations, with tens of thousands of post offices and hundreds of thousands of employees. The Postal Service began operating in 1971, when it replaced the United States Post Office Department. The Postal Service has headquarters in Washington, D.C.

The central tasks of all postal administrations are the collection, sorting, and delivery of mail. For descriptions of these processes, see Postal services (How mail is delivered). This article focuses on the procedures, services, and history specific to the United States Postal Service.

Classes of mail

The Postal Service divides all domestic mail into five classes. These classes are (1) Express Mail® service, (2) First-Class Mail® service, (3) periodicals, (4) standard mail, and (5) package services. Each class of mail has its own rate structure. The Postal Service sorts mail using *ZIP Codes.* ZIP Codes are sets of numbers that signify particular *zones,* or geographical areas. The name stands for *Z*one *I*mprovement *P*lan.

Express Mail service travels faster than any other class of mail. This service guarantees next-day delivery to specified locations throughout the country. If the mail does not reach its destination by the next day, the Postal Service refunds the cost of the postage to the sender.

First-Class Mail service includes letters, postal cards, and other material that is at least partly written. First-Class Mail service costs more and travels faster than any other class of mail except Express Mail service. Priority Mail® service is First-Class Mail service for items weighing more than 13 ounces (0.37 kilogram). Mailers also have the option to send items weighing less than that amount by Priority Mail. In most cases, the mail is delivered in two days.

Periodicals is a class of mail consisting of magazines, newspapers, and other publications formed of printed sheets. These are items that are issued at least four times a year at regular, specified intervals from a known office of publication. Periodicals usually must have a list of subscribers or a list of requests.

Standard mail consists of all mail items weighing less than 1 pound (0.45 kilogram) that are not included in First-Class Mail service. Such mail includes newspapers, magazines, newsletters, and bulletins that do not meet the requirements for the periodicals class, as well as advertising circulars, catalogs, and lightweight merchandise samples.

Package services involve the shipment of all mail weighing 1 pound (0.45 kilogram) or more that is not considered First-Class Mail or periodicals. The Postal Service also offers special rates to people who send books, other bound printed matter, and library materials by mail. Package mail that does not qualify for such special rates is called Parcel Post® service.

Post office services

In addition to providing the different classes of mail service, the Postal Service has many other functions. It sells materials and supplies, and it offers a variety of specific mail options.

Stamps and other mailing materials. Stamps are placed on packages and letters as proof that the sender has paid for mailing the item. At times, the Postal Service issues special *commemorative stamps.* Some commemoratives honor distinguished people who have died. Others pay tribute to historic events, places of scenic beauty, or outstanding organizations.

Post offices also sell *stamped envelopes, postal cards,* and *air letters.* Stamped envelopes and postal cards come with postage already printed on them. Postal cards differ from post cards, which are made by private companies and carry no postage. Air letters are light-

United States Postal Service

The delivery of mail is one of the main services provided by the United States Postal Service. Many letter carriers drive special Postal Service vehicles along their routes.

weight sheets of paper that can be folded to form envelopes.

Special handling is a service that enables customers to send standard mail and packages faster than normal. Mailers must pay an extra fee for this service, which provides preferential treatment in sending and transportation, but not in delivery.

Extra protection. Some services provide special protection for the items postal customers send through the mail. Customers must pay an extra fee for these services, which include *insurance, registered mail,* and *certified mail.* Insurance pays, up to a certain amount, the value of items lost or damaged in the mail. Registered mail provides protection for irreplaceable items or for particularly valuable items. Certified mail is a special service that provides the sender with a receipt at the time of mailing. Return receipts, issued at the time of delivery, are available for additional fees.

Electronic services. The Postal Service has introduced several programs to take advantage of computer and Internet technology. *NetPost Mailing Online* enables people to create a message on a computer and send it electronically to the Postal Service. The Postal Service, in turn, prints the message and delivers it to its destination. An electronic bill-paying system called *USPS eBillPay* allows users to receive and pay bills online. The *Post Electronic Courier Service* allows users to send electronic documents securely through the Postal Service.

Other services. Post offices sell *postal money orders,* which enable customers to transmit money for a fee. The Postal Service refunds the value of postal money orders that are lost or stolen in the mail. In addition, the Postal Service rents *post office boxes,* which stand in post office lobbies and at various off-site locations. All mail addressed to a box number stays in the box until the boxholder collects it.

Other services offered by post offices include *COD service* and *metered postage.* COD, which stands for *collect on delivery* or *cash on delivery,* enables a person to order merchandise by mail and pay for it when it arrives. *Postage meters* are devices that companies use in their offices to print the postage and postmark directly on envelopes. Companies lease the meters from an authorized manufacturer, then obtain a permit from the Postal Service to use them.

The Postal Service also publishes postal manuals and the *National Five-Digit ZIP Code and Post Office Directory.*

Organization

An 11-member Board of Governors directs the Postal Service. Nine of the members are appointed by the president, with the advice and consent of the Senate. These members appoint the postmaster general, who becomes the 10th member of the board and serves as the chief executive officer of the Postal Service. These 10 members, in turn, appoint the deputy postmaster general, who becomes the 11th board member and the postmaster general's chief assistant. The postmaster general and the deputy are responsible for day-to-day operations.

The executive branch of the U.S. government also has an independent five-member Postal Rate Commission. The members are appointed by the president with the advice and consent of the Senate. They recommend postal rates and classifications for adoption by the Board of Governors.

History of postal services in the United States

Colonial times. The first known official postal system in the American Colonies appeared in 1639 in Boston. In most places, taverns or inns served as post offices. In 1691, King William III of England gave Thomas Neale, a colonial official, the right to provide mailing services in the colonies. Neale's deputy, Andrew Hamilton, created the colonies' first national postal system. In 1707, the British government took control of the system. Shortly afterward, it greatly increased postal rates.

Benjamin Franklin became a deputy postmaster general for the American Colonies in 1753. He improved the frequency and reliability of mail delivery. However, rates remained high. The American colonists fiercely opposed the high rates, which they considered an unfair tax. As a result, many of the colonists avoided using the royal postal system and sent letters by private, illegal carriers.

After the Revolutionary War in America (1775-1783) began, the Second Continental Congress named Franklin the first postmaster general of the United States. The nation won its war for independence in 1783. In 1789, Congress gave the federal government the sole power to provide mailing services. Samuel Osgood became the first postmaster general to serve under the new Constitution.

During the 1800's and early 1900's, mailing services grew rapidly in the United States. Congress issued the

Parcel Post Stamp—Issue of 1912-1913

The first railway mail cars began operating in 1864. The first official test run of this service was made on August 28, between Chicago and Clinton, Iowa.

Overland mail traveled by stagecoach from Missouri to California. It followed a southern route via Texas. The trip took 25 days.

Parcel Post Stamp—Issue of 1912-1913

Rural free delivery started in 1896. In the first week, patrons received 214 letters, 33 postal cards, and 2 packages, and sent 18 letters and 2 packages.

Pony Express Commemorative Stamp—Issue of 1940

Pony express riders carried U.S. mail between St. Joseph, Missouri, and Sacramento, California. They generally rode almost 2,000 miles (3,200 kilometers) in about 10 days.

Airmail Stamp—Issue of 1918

The first regular airmail service in the world was inaugurated in 1918. The flight was between Washington, D.C., and New York City.

first postage stamps in 1847 and began to require the prepayment of postage in 1855.

The pony express was one of the most colorful episodes in American postal history. In 1860 and 1861, daring horseback riders carried mail from St. Joseph, Missouri, to Sacramento, California, in about 10 days. In 1861, the transcontinental telegraph eliminated the need for the pony express.

In 1863, the U.S. Post Office Department established three classes of mail and began to provide free delivery in many cities. Other services that were introduced in the middle and late 1800's included postal money orders, special delivery, and postal cards. In 1913, the Post Office introduced parcel post service, insured mail, and COD service. In 1943, the department divided major cities into numbered postal zones.

Technological advancements. The development of modern means of transportation improved the speed and reliability of mail delivery. In 1864, the Post Office officially established the railway post office. In 1911, an American pilot named Earle Ovington made the first official airmail flight in the United States. In 1918, airplanes began to carry mail regularly. Since 1975, nearly all First-Class Mail service going more than 200 miles (320 kilometers) has traveled by air.

In the 1960's, the department began to use high-speed equipment to perform many of the tasks previously done by hand. The 1963 introduction of ZIP Codes allowed the Post Office to sort large volumes of mail mechanically. Additional advancements further modernized the postal system's operations and increased the speed of mail processing.

Establishment of the Postal Service. Until 1970, the Post Office followed a policy of providing low-cost mail service to customers regardless of what it cost the department. As a result, the department's expenses usually exceeded its earnings. Each year, Congress gave the Post Office money to make up for the losses.

On Aug. 12, 1970, President Richard M. Nixon signed a bill to replace the Post Office Department with the new United States Postal Service. The bill also removed the postmaster general from the Cabinet. The Postal Service began operating on July 1, 1971. Since 1983, the agency has become essentially self-supporting.

Since the 1970's, the Postal Service has developed a variety of programs to automate mail processing and to provide more efficient service. These developments have included new delivery standards and mail categories, discounts for presorted mail, expanded ZIP Codes with additional digits, the increased use of bar codes for electronic sorting, and additional electronic mail options.

At a post office, customers buy stamps, envelopes, and other postal supplies, send money orders, and register packages to be mailed. Other postal services include the renting of post office boxes and the collection, sorting, and delivery of mail.

Postal services

Postal services, also called mail services, are the procedures involved in the collection, handling, and delivery of letters, messages, and packages. *Post offices* are places where mail is handled and postal materials and services are sold. The terms *postal service* and *post office* can also refer to a government agency that provides mail services. In the United States, the government agency that provides mail services is called the United States Postal Service. In the United Kingdom, it is called the Post Office. India Post provides similar services in India, as does An Post in Ireland. In Australia, the postal service is the Australian Postal Corporation, which operates under the name Australia Post; in Canada, it is the Canada Post Corporation, or Canada Post.

Mail is perhaps the one service of central government that touches nearly every citizen on almost a daily basis. Indeed, in many small towns, the post office is the only government building. By means of letters, people can share news and make plans with friends and relatives far away. Businesses send bills and receive payments through the mail. Most magazines and mail-order catalogs are delivered by mail.

Postal services have played a major role in the building of nations and the uniting of people throughout history. In ancient times, an extensive system of messenger routes served to knit the Roman Empire together. In Australia, Canada, and the United States, the postal services helped promote democracy by uniting citizens who were scattered over a vast continent. Until well into the 1900's, the postal services were the primary vehicle for communication and marketing.

The postal industry is big business. Postal agencies are large organizations, traditionally government-run, with many complicated managerial and economic concerns. The United States Postal Service, for example, is the country's largest single employer of civilian labor, with about 900,000 full- and part-time employees. About 80 percent of the costs of postal administrations go for payrolls and other labor expenses.

Mail service has long ranked as a vital public service, as well as a source of revenue for the government. Postal systems traditionally have an obligation of *universal postal service*—that is, a duty to deliver to every address in the country and to charge the same rate regardless of location and distance. Maintaining universal postal service would be difficult or impossible without government intervention. For this reason, most governments have provided national post offices with a legal *monopoly,* the right to be the only provider of certain types of mail service.

Although the post is an old and important institution, mail services worldwide have gone through great change. New electronic means of communication challenge the traditional role of mail for personal and business communication. In addition, the rise of private courier firms that provide shipping and delivery services has brought increased competition to the postal industry. The question of how to react to competition from new technologies and from private firms, while still upholding its universal service obligation, is a vital one for mail service today.

How mail is delivered

The sending of a letter or package is a long, complicated process. Many people and machines handle the mail before it reaches its destination. This section describes what happens to mail as it travels from the sender to the receiver.

Collection. A person can mail a letter by taking it to a post office, by dropping it into a mailbox, or by handing it to a postal worker. Senders place *postage stamps* on letters as proof that they have paid the mailing charges in advance. Many towns and cities maintain mailboxes, also called *collection boxes,* along many streets. Many large office towers and apartment buildings also have

mailboxes. Postal employees called *letter carriers* take the letters and packages from the mailboxes to a nearby post office.

Sorting. Outgoing mail is first sorted at the *originating post office,* the postal facility near the sender. There, postal clerks put the newly collected mail into trays. They bundle packages separately. From the post office, the mail travels by truck to a central facility, sometimes called a *management sectional center.* These centers process nearly all the mail coming from or going to their regions.

Workers called *mail handlers* empty the trays of mail onto moving conveyor belts. The belts carry the mail to a machine called an *edger-feeder,* which separates the mail according to envelope size. The edger-feeder moves the letters into another machine known as a *facer-canceler.* Sensing devices in the facer-canceler find the stamp or facer identification mark on the envelope. These sensors enable the machine to arrange the letters so they all face the same way. The facer-canceler cancels stamps by printing black lines over them so they cannot be used again.

Mail then moves to computerized machines called *optical character readers.* These machines "read" the address on a letter and then spray a pattern of lines and bars known as a *bar code* onto the envelope. Machines called *bar code sorters* then read the codes and sort the mail according to region. Some businesses print their own bar codes on their outgoing mail; these precoded items skip the optical character readers and go directly to the bar code sorters.

If an optical character reader cannot read the address on a piece of mail, the rejected mail may be sent for *remote video encoding.* In this process, an image of the address is scanned and stored in a computer, where computer programs and operators attempt to read the address. If the process succeeds, an operator codes the item and sends it to the bar code sorter. If the process does not succeed, the address is read by a human being, and the mail is sorted accordingly.

Mail addressed to locations outside the region served by the central facility travels by truck, airplane, or train to other central facilities. The mail is then sorted mechanically or by hand into bundles for each delivery route served by the center. Finally, postal workers transport the mail to local post offices for delivery.

Delivery. At local post offices, letter carriers receive the mail for businesses and homes along their routes. They arrange the mail in the order in which they will deliver it by putting it into cases that have slots for each address. In some areas, letter carriers receive mail that has already been sorted by a bar code sorter. Some letter carriers walk their entire route. Most letter carriers, however, drive cars or special postal service vehicles.

The history of postal services

Ancient times. Many ancient civilizations, including the Chinese, Egyptians, Assyrians, and Persians, had well-organized mail systems. These early postal networks existed to help rulers govern empires that stretched over large areas. Generally, only government officials could use the postal system. There was little demand for public mail service because few people could read or write.

Nearly all ancient postal systems were *relay systems.* They consisted of runners or mounted couriers stationed at intervals along major roads. Messages relayed by these couriers traveled swiftly, sometimes more than 100 miles (160 kilometers) a day. In the 500's B.C., the Persian Empire, based in what is now Iran, developed an efficient relay system of mail delivery by couriers on horseback. Herodotus, a Greek historian of the 400's B.C., described the Persian messengers by writing, "Neither snow/ nor rain/ nor heat/ nor gloom of night stays these couriers from the swift completion of their appointed rounds." These words are inscribed on the central post office building in New York City.

The most highly organized mail system of ancient times was established by Augustus Caesar, who became the Roman emperor in 27 B.C. It was a relay system in which mounted couriers rode throughout the empire on a network of well-constructed roads. Along the roads, the Romans built relay stations called *posthouses.* There, messengers could rest, get fresh horses, or pass their messages to another courier. In the A.D. 200's, Roman couriers began to deliver a limited amount of private mail, as well as official messages.

The fall of the West Roman Empire in the A.D. 400's led to the collapse of the postal system. Rulers in some areas continued to use Roman roads and posthouses for their own postal services. But generally, organized communication ended throughout Western Europe.

Meanwhile, many civilizations in other areas of the world developed efficient postal systems. In North and South America, the Aztec and the Inca established networks of relay runners, who delivered messages and packages between major cities. In Asia, the Mongol leader Kublai Khan developed a highly organized postal relay system, with more than 10,000 postal stations, during the 1200's.

The growth of public mail systems. During the 1300's, the growth of international commerce led merchants and trading companies to establish their own courier services. Universities, religious groups, and *guilds* (organizations of skilled workers) also maintained mail service for their members. However, service was slow, expensive, and unreliable.

The invention of the printing press and the growth of education and learning during the 1400's increased the demand for postal services. Delivering mail became a profitable business, and private mail services sprang up in many areas. The Thurn and Taxis family organized one of the most famous private systems in the Holy Roman Empire, which covered what are now Austria, the Czech Republic, Germany, the Netherlands, Switzerland, and part of Italy. Generally, however, service remained costly and slow. In addition, mail services only delivered mail along major transportation routes.

The rise of strong centralized governments in Europe in the late 1400's and the 1500's led to the establishment of official postal services. In 1477, King Louis XI of France created a postal system of mounted couriers with regular schedules. By the end of the 15th century, the Thurn and Taxis family resurrected the old Roman postal system and began what would become a courier service connecting the monarchs of Europe. In the early 1500's, King Henry VIII of England organized a courier system in his own country.

What happens to a letter

Mailing a letter to a friend is just the first step in a long, complicated process. Before your friend receives the letter, it will be handled by many people and numerous machines. The three main stages in the process are collection, sorting, and delivery.

A special postal service vehicle departs from the local post office and carries the mail on its delivery route. Some letter carriers do not use vehicles and instead walk their entire routes.

© Consignia

A letter carrier delivers the mail to its final destination. Many carriers park their vehicle on every block along the route and make deliveries on foot.

During the early 1600's, many European governments established public postal systems. In 1627, the French government established post offices in major cities and regulated postal rates. Many countries passed laws giving the government the sole power to provide postal delivery. However, private mail services continued to operate in these countries, mostly along routes not covered by government postal systems.

The creation of the Penny Post. The development of mail service in England soon surpassed that on the European continent. In 1635, King Charles I, motivated largely by the need to raise money, became the first English monarch to offer mail services to his subjects. In 1680, a merchant named William Dockwra organized the London Penny Post, which delivered mail anywhere in London for a penny. Dockwra introduced the practice of postmarking letters to indicate when and where they had been mailed. The London Penny Post became so successful that the government took control of the operation in 1682.

During the 1700's, a program to improve the condition of public roads in England greatly increased the speed at which mail traveled. In the late 1700's, the British government further improved postal service by sending mail on stagecoaches.

In 1837, a retired British schoolteacher named Rowland Hill wrote a pamphlet titled *Post Office Reform.* In it, he called for a uniform penny post, which would charge cheap, uniform postage rates, regardless of distance. At that time, the cost of sending a letter depended on how far it had to travel. Hill also proposed that postage should be paid in advance by the sender, with adhesive stamps to indicate payment. Previously, the letter carrier collected postage from the addressee unless postal officials had written "Paid" on the letter. In addition, Hill suggested the use of envelopes. Until that time, letters were merely folded and sealed with sealing wax. The British Post Office issued the first postage stamps in 1840 and later adopted many of Hill's other ideas. Following the introduction of the uniform penny post, the British system became the model for postal systems around the world.

During the middle and late 1800's, mail volumes increased dramatically. This expansion resulted in efforts to develop cooperation in postal communications between countries. In 1874, 22 countries attended an international postal conference in Bern, Switzerland, to organize and improve the flow of mail between nations. The conference established the General Postal Union, which began functioning in 1875. The name was later changed to the Universal Postal Union.

Postal service in the United States. The first official postal system in the American Colonies was established in 1639 in Boston. The Massachusetts Bay Colony gave a tavern owner named Richard Fairbanks the right to process mail to and from overseas locations. In 1691, King William III of England gave Thomas Neale, a colonial official, the sole right to provide postal services in the American Colonies. In 1707, the British government took control of Neale's system.

After the Revolutionary War in America (1775-1783) began, the Continental Congress named statesman and inventor Benjamin Franklin the first postmaster general of the United States. In 1789, after the nation had won its independence, Congress gave the federal government the sole power to provide postal services.

During the 1800's and early 1900's, postal services grew rapidly in the United States. In 1863, the U.S. Post Office Department began to provide free delivery in many cities. In 1918, airplanes began to carry mail regularly. In 1943, the department divided major cities into numbered postal zones. In 1971, Congress replaced the Post Office Department with the United States Postal Service, an independent agency in the executive branch of the government. For more information on the U.S. Postal Service, see **Postal Service, United States.**

The Penny Black was the world's first postage stamp. The British Post Office issued the stamp, with a picture of Queen Victoria, in 1840.

The use of stagecoaches to deliver mail began in the 1700's and greatly improved the speed of postal services. This photo shows a mail coach in London in the 1800's.

AP/Wide World

Private courier firms, such as Federal Express and the United Parcel Service, have taken much of the package shipment business away from government postal services.

Canadian mail service. The first organized postal service in Canada began in 1693, when Pedro da Silva transported letters between Montreal and Quebec City. At this time, most of Canada was controlled by either English or French colonists. In 1755, Canada's first government post office opened, under the administration of the British Post Office.

Canada took over responsibility for its postal services in 1851, and it created the Post Office as a department of the Canadian government in 1868. Canada won complete independence from the United Kingdom in 1931. The Canada Post Corporation Act, passed in 1981, created the Canada Post Corporation to operate the mail system.

Modern developments

Postal services in their modern form have resulted from a long line of advances, both cultural and technological. The introduction of steamboats, trains, automobiles, airplanes, and new machinery have been vital to the industry's growth since the 1800's. Since the mid-1900's, new developments have further improved the mail process in many ways, but they have also brought new challenges to the postal services.

Technological advancements. In the 1960's, many post offices began using high-speed equipment to perform much of the work previously done by hand. Since then, mail processing has gone through sustained technological innovation. The changes in technology in part stem from innovations in computers, telecommunications technology, and optical character reading.

A major application of these innovations has been the large-scale sorting of mail. Computerized machines, such as optical character readers and bar code sorters, enable post offices to quickly sort large amounts of mail with minimal costs. Many of these machines require fewer workers or less worker training, and some can be operated remotely.

Throughout this period of technological advancement, postal services had to contend with alternative methods of communication. Such innovations as the telegraph, telephone, and fax machine offered new, fast ways to share information. But although phone calls and faxes reduced the use of mail for certain types of communication, the demand for mail remained strong.

A new type of competition emerged in the 1990's, with the increased use of personal computers and the Internet. Computer users transmitted many messages that were once sent by mail by *e-mail* (electronic mail). In addition, many people began doing their shopping, banking, and business transactions over the Internet.

Competition from the Internet had a particularly great impact on traditional letter mail, known in the United States as first-class mail. This class of mail—used mainly for messages, invoices, and bills—is the class most easily replaced by electronic communication. The Internet also affected advertising mail, known in the United States as *standard mail,* as companies shifted some of their advertising to the World Wide Web. The demand for shipment of *parcels* (boxes and packages), on the other hand, grew with the rise of the Internet. This increased demand resulted, in part, because items purchased over the Internet still had to be shipped to the customer.

These changes have serious implications for the future funding of postal services and for the maintenance of universal service. If the demand for letter mail and advertising mail further decreases, as many experts expect, postal services worldwide may lose revenue and be forced to increase their rates and adjust their policies. Many postal systems, including the U.S. Postal Service, are themselves working to provide communication and bill payment by electronic means.

Competition and privatization. In addition to coming to terms with technological innovations like those just described, postal administrations face competition from private companies. For example, courier firms, such as the United Parcel Service, have taken much of the parcel business away from the United States Postal Service. Postal services are limited in their ability to raise parcel rates, because parcel shipment is not subject to the same monopoly protection that covers letter mail.

In addition, some private firms offer *presorting* services in competition with traditional mail services. Presorting refers to any sorting of mail that occurs before the postal service handles it. For example, a presorting company working for a newspaper or magazine, at least in the United States, may sort the mail and drop it off at the post office. Businesses find that they can afford presorting services, in part, because national post offices give a discount to mailers who presort their own mail.

A large number of people believe that mail delivery can function better as a competitive business than as a government monopoly. As a result, many countries have been *privatizing* their postal systems—that is, transferring certain operations and responsibilities from government agencies to privately owned companies. For instance, the Dutch Post Office is a private company with stock held both by the Netherlands government and by private individuals. Germany began to privatize its post office, Deutsche Post, in 2000. In other countries, a government postal administration may simply hire private firms to handle certain tasks.

Postal Union, Universal (UPU) is a specialized agency of the United Nations that sets rules for the free flow of mail between countries. It works to promote cooperation in organizing and improving postal services. The UPU provides postal technical assistance to its approximately 170 member countries, which make up a single postal territory for exchanging mail.

The UPU operates under an international agreement called the Universal Postal Convention. The convention lists postal rates and uniform procedures for handling first-class mail, including letters, post cards, and small packets. Under the convention, member countries set postal charges within specified limits. If a country's postal service receives a greater number of mail items than it sends, it is entitled to collect the cost of handling this excess mail from the sender country. Separate agreements govern other services, such as parcel post, newspaper and magazine subscriptions, insured letters and boxes, and money orders.

The Universal Postal Congress is the main legislative body of the Universal Postal Union. It usually meets every five years in a member country to review and amend the convention. UPU legislation takes precedence over any conflicting national laws. But, some provisions are optional.

The Executive Council is a permanent body that handles UPU affairs between congresses. It consists of 40 members, elected on the basis of geographical representation. The Consultative Council on Postal Studies conducts technical research in international postal matters. It has 35 members. The International Bureau is the UPU's permanent secretariat. The bureau may also act as an information center and clearinghouse for settling the financial accounts of the UPU.

The first international postal congress was held by 22 countries in 1874 in Bern, Switzerland. The first postal convention went into effect in 1875. The Universal Postal Union received its present name in 1878 at the second postal congress. The UPU became a specialized agency of the United Nations in 1947. The UPU has headquarters in Bern.

Critically reviewed by the Universal Postal Union

Poster is a printed sheet of paper or cardboard displayed in public. Most posters convey a simple message using words and illustrations. Posters may announce events, such as plays, films, or art exhibits. They may also advertise commercial products or convey political messages.

A typical poster emphasizes simple shapes, bright colors, and large letters to attract attention. Most posters are large enough to be seen from a distance. They are often posted on walls and places along streets where the public can easily see them. Many posters are so large that they are placed on billboards. Commercial posters are usually made by photography, lithography, and silk-screen printing.

Designing posters became popular with European artists in the 1800's. Beginning about 1866, the French artist Jules Chéret produced more than 1,000 large colorful posters using the recently invented process of color lithography. In the 1890's, the French artist Henri de Toulouse-Lautrec gained fame for the beautiful bold designs of the posters he made for theaters and dance halls. Many artists in the 1900's designed posters that are collected as works of art. Elizabeth Broun

Postimpressionism is the name applied to several styles of painting that arose in Western Europe, especially France, in the 1880's and 1890's. Postimpressionism followed the art movement known as Impressionism.

Impressionist painters sought to capture a direct experience of the natural world. They rebelled against the idealized, carefully finished paintings of the prevailing academic style. Unlike the academic painters, the Impressionists did not try to give their art a theoretical, moral, or emotional significance. The Postimpressionists attempted to move beyond the ideas and techniques of Impressionism. Postimpressionist painters added emo-

tional or symbolic meanings to their work. In this way they helped bring about the transition from impressionism's faithfulness to nature to Fauvism, cubism, and abstract styles of the 1900's.

The English art critic Roger Fry coined the term *postimpressionism* in 1910 for an exhibition of modern painting he organized in London. The most important postimpressionists were the French artists Georges Seurat, Paul Gauguin, and Paul Cézanne; and the Dutch painter Vincent van Gogh. Ann Friedman

Each painter mentioned in this article has a biography in *World Book*. See also **Impressionism; Painting** (Postimpressionism; pictures).

Postmodernism is a term often applied to artistic styles that emerged in the mid-1900's. Art critics and historians do not agree on exactly when Postmodernism started or who began it. They do generally agree that it developed as a reaction to and a rejection of a widespread style of the earlier 1900's called *modernism.*

Modernist artists and designers preferred simple, geometrical, and clean-looking forms that were uncluttered and practical. Modernism advocated geometrical abstraction and sleek, streamlined designs. Postmodern artists and designers revived the styles of older art movements. Through this revival, Postmodernism introduced complexity, figurative ornament, and cluttered or mixed-up forms. Modernism stressed originality, newness, and the economy of line, shape, and color. Postmodernism stressed the revival of tradition, and often featured the plentiful use of texture, shape, color, or line. Modernist art emphasized individual expression. Postmodern art stressed collective or shared expression through collaboration and a blend of borrowed styles called *pastiche.*

In the fine arts, Postmodernism is probably most visible in the works of several American architects. A typical Postmodern building reflects elements of historical styles ignored by earlier modern architects. Unlike modernist structures, Postmodern buildings often feature ornamentation on their exteriors. The most notable Postmodern architect and theorist is Robert Venturi. Other Postmodern architects include Peter Eisenman, Michael Graves, Philip Johnson, Charles Moore, Robert Stern, James Stirling, and Stanley Tigerman.

Social critics have also used the term *Postmodernism* to define changes in our way of life. For example, a Postmodern society is more decentralized, fragmented, and impermanent than a modernist society. The characteristics of a Postmodern society can be seen in the fragmentary poetry of the American writer John Ashbery, in the experimental works of the American composer John Cage, and in the symbol-filled pictures of the American photographer Cindy Sherman. Herman Rapaport

Post-traumatic stress disorder is a psychological illness in which people repeatedly remember, relive, or dream about a terrible experience. The disorder may result from experiencing or witnessing a natural disaster, warfare, a personal assault, or any other violent or life-threatening incident. Because many soldiers involved in combat develop the disorder, it was formerly known as *battle fatigue, combat fatigue,* or *shell shock.*

A person with post-traumatic stress disorder (PTSD) experiences symptoms for more than one month following a psychological *trauma* (severely upsetting event). The chief symptoms of PTSD include repeated dreams, memories, and *flashbacks* (vivid, involuntary recollections) of the incident. Other symptoms include sleeplessness, difficulty concentrating, and being easily startled. Emotional signs include feelings of anger, fear,

Invitation to the Sideshow (La Parade) (1888), an oil painting on canvas; Metropolitan Museum of Art, bequest of Stephen C. Clark, 1960

Postimpressionism followed Impressionism as a major art movement in the late 1800's. One of the leading Postimpressionist painters was Georges Seurat of France. He developed a style called *pointillism* in which the artist creates a painting by placing dots of pure color side by side. The painting at the left shows Seurat's pointillist style. Other Postimpressionist artists developed their own styles.

helplessness, or guilt. Some patients develop emotional numbness and feelings of isolation from others. Children may show restlessness, repeat the trauma in play, or have frequent nightmares.

PTSD may persist for many years. Some people held as prisoners of war or concentration camp inmates during World War II (1939-1945) showed symptoms of the condition more than 50 years later. Treatment of PTSD involves psychotherapy and, often, medication. Prompt treatment following the trauma may help prevent PTSD or lessen its severity. Theodore Nadelson

Postulate. See Geometry (Axiomatic organization).

Posture is the position of a person's body while standing or sitting. Posture is determined by the person's ability to maintain balance against the force of gravity, which constantly pulls the body downward. The action of certain muscles keeps the body upright. These muscles include those that keep the back, hips, and knees from bending. Because of the constant give and take of the pull of gravity and of muscle action, posture is a dynamic, ever-changing state.

Good posture requires the least amount of muscle activity to breathe well and to maintain an upright position. The feet should be placed comfortably apart, with the weight distributed evenly over both feet. From a front or back view, the shoulders, the hips, and the fingertips should be approximately aligned. From a side view, the ear and the shoulder should be aligned, and that line projected downward should fall in front of the middle of the knee. The back should not be excessively arched. The arches of the feet should be visible without conscious effort.

Posture is an indication of the way people have stood or sat for much of their lifetime. If a person constantly stands or sits with the head hanging forward, the neck muscles change in length, and good posture becomes hard. All body parts work together, so getting one part, such as the head, out of alignment will cause other parts also to be out of alignment. The further away one's body parts are from the body's center of gravity, the more the muscles will have to work to keep the body upright. When this happens, fatigue and stress result.

Posture also may indicate the way people feel. If they are tired or depressed, their posture may be poorer than usual. Changes in posture may affect a person's appearance, gait, and personality. Good posture gives an impression of poise and self-confidence, and may allow the body to function at its best. Learning about body function and body relaxation can help improve posture.

Mary T. Moffroid

Pot, a drug. See Marijuana.

Potash, *PAHT ash,* is the commercial name for a group of salts containing the element potassium. The most important type of potash is *potassium chloride* (KCl), which is mainly used to make fertilizer. About 95 per cent of the potash that is processed throughout the world is refined for fertilizers. Potash is also used in the manufacture of soaps and detergents, glass, ceramics, textiles, dyes, chemicals, and drugs.

The mineral sylvite is the chief potash ore. Most potash ore is found in underground salt beds that formed when ancient seas evaporated. The deposits are usually obtained by a method of mining called the *room-and-pillar* system (see Mining [Underground mining methods]). Potash also occurs in salt lakes. Potash is graded according to its *potassium oxide* (K_2O) *equivalent,* a standard that measures potassium content. The K_2O equivalent is also used to determine how much potash a mine will produce.

Potash was originally obtained by running water through wood ashes and boiling the resulting solution in large iron pots. The substance that formed, *potassium carbonate* (K_2CO_3), was called *pot ash.* The United States imports two-thirds of its potash supply from Canada. Most of the potash produced in the United States comes from New Mexico. Robert J. Ouellette

See also Potassium.

Potassium, *puh TAS ee uhm,* is a silvery metallic element. It reacts readily with both oxygen and water. In nature, because of this characteristic, potassium always occurs combined with other elements. It is found in the form of minerals, such as carnallite and sylvite. Sir Humphry Davy, an English chemist, first isolated potassium as a pure metal in 1807.

Potassium, with a density of 0.856 gram per cubic centimeter at 20 °C, is the lightest metal except lithium (see Density). It is so soft that it can be cut with a knife. Potassium has an atomic number of 19 and an atomic weight of 39.0983. Its chemical symbol is K. Potassium belongs to the group of elements called *alkali metals* (see Element, Chemical [Periodic table of the elements]). It melts at 63.2 °C and boils at 766 °C. One isotope of the element, potassium-40, is radioactive. The age of a substance can often be determined by analyzing the amount of potassium-40 it contains.

Potassium is a relatively abundant element and makes up nearly $2\frac{1}{2}$ percent of the earth's crust. Large deposits of its principal compounds, including potassium chloride and potassium sulfate, occur in parts of Canada and Germany. The Dead Sea is another major source of potassium compounds.

Scientists have developed a wide variety of uses for potassium and its compounds. Potassium metal, used chiefly in sodium-potassium alloys, is usually obtained from molten potassium chloride through a special chemical process. These alloys, which are liquids at room temperature, are used in the heat-transfer systems of some types of nuclear reactors called *fast breeders.* Manufacturers use potassium carbonate, also called *potash,* in making certain kinds of glass and soaps. They use potassium nitrate, known as *saltpeter,* in producing matches and explosives. Some potassium compounds are used for medical purposes. For example, potassium bromide is a sedative, and potassium iodide promotes the discharge of mucus from the nose and from the throat.

Plants require potassium for growth. Therefore, soil must contain potassium compounds to produce crops of high quality and yield. Potassium chloride is widely used in commercial fertilizers for most crops. But potassium sulfate is a better fertilizer for tobacco and crops that would be harmed by chloride.

Potassium also is essential for human beings and other animals. It plays a part in *metabolism,* the process by which organisms change food into energy and new tissue. For example, potassium helps enzymes speed up some chemical reactions in the liver and the muscles. Such reactions produce an important carbohydrate

called *glycogen,* which regulates the level of sugar in the blood and helps provide energy for the muscles. Potassium, together with sodium, also contributes to the normal flow of water between the body fluids and the cells of the body. A daily diet that includes fruit, vegetables, and meat supplies enough potassium for the normal needs of the human body. Duward F. Shriver

Potato is one of the world's most widely grown vegetables and most important foods. Potatoes have a high nutritional value and are grown in most countries.

Potatoes are prepared in various ways—baked, boiled, French-fried, fried, and mashed—and are served with meat or fish and with other vegetables. Food processors make potatoes into potato chips, instant mashed-potato powder, and other products. Food canners use potatoes in such foods as hash, soup, and stew. Other products whose ingredients may include potatoes are alcoholic beverages, flour, and certain starches used in industry.

A potato consists of about 80 percent water and 20 percent solid matter. Starch makes up about 85 percent of the solid material, and most of the rest is protein. Potatoes contain many vitamins, including niacin, riboflavin, thiamine, and vitamin C. They also contain such minerals as calcium, iron, magnesium, phosphorus, potassium, sodium, and sulfur.

Potatoes are not especially fattening unless flavored with butter, gravy, or sour cream. An average-sized baked potato that weighs from 6 to 8 ounces (170 to 225 grams) contains fewer than 100 calories.

WORLD BOOK illustration by James Teason

Potatoes rank among the most important and nutritious of all foods. People prepare them in many different ways. Eight of the several hundred potato varieties are illustrated here.

The world's potato growers produce about 340 million tons (310 million metric tons) of potatoes annually. China grows more potatoes than any other country. Other leading potato-growing countries include India, Poland, Russia, Ukraine, and the United States.

The United States produces more than 20 million tons (18 million metric tons) of potatoes yearly. Idaho and Washington are the leading potato-growing states. Among the Canadian provinces, Prince Edward Island is, by far, the leading potato producer.

Leading potato-growing countries

Tons of potatoes produced in a year	
China	67,509,000 tons (61,243,000 metric tons)
Russia	36,135,000 tons (32,781,000 metric tons)
India	27,047,000 tons (24,537,000 metric tons)
United States	23,920,000 tons (21,700,000 metric tons)
Poland	23,722,000 tons (21,520,000 metric tons)
Ukraine	16,925,000 tons (15,354,000 metric tons)
Germany	14,116,000 tons (12,806,000 metric tons)
Belarus	9,152,000 tons (8,303,000 metric tons)
Netherlands	9,039,000 tons (8,200,000 metric tons)
United Kingdom	7,505,000 tons (6,809,000 metric tons)
France	7,288,000 tons (6,611,000 metric tons)

Figures are for a three-year average, 1999-2001.

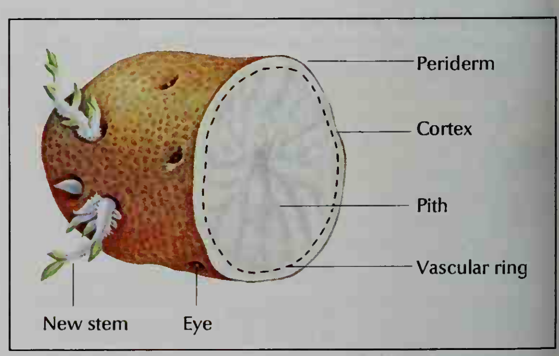
Several hundred kinds of potatoes are grown in the United States. The *Russet Burbank* ranks as the most popular variety. People eat Russet Burbanks fresh and as processed potato snacks. Another variety, the *Russet Norkotah,* is sold mostly in the fresh potato market. The *Ranger Russett* and *Shepody* potatoes most commonly appear in processed foods. Other potato varieties include the *Cobbler, Katahdin, Kennebec, Norchip, Red La-Soda, Red Pontiac,* and *White Rose.*

The potato plant

The edible parts of a potato plant are growths called *tubers,* which form underground on the stems. Most potato plants have from 3 to 6 tubers. Some have from 10 to 20, depending on the variety, the weather, and soil conditions. Potatoes are round or oval and rather hard. They may grow more than 6 inches (15 centimeters) long and weigh as much as 3 pounds (1.4 kilograms). Their skin is thin and may be brown, reddish-brown, pink, or white. The inside of a tuber is white, and potatoes are often called *white potatoes* to distinguish them from a vegetable called the *sweet potato.*

Tubers consist of several layers of material. The outer skin is called the *periderm.* The next layer, the *cortex,* serves as a storage area for protein and some starch. The third layer, known as the *vascular ring,* receives starch from the plant's leaves and stem. The starch moves out of the vascular ring to surrounding tissue made up of *parenchyma cells.* These cells are the tuber's main storage areas for starch. The center of the tuber, called the *pith,* consists mostly of water.



The part of the plant that grows aboveground has spreading stems and coarse, dark green leaves. The potato plant grows from 3 to 4 feet (90 to 120 centimeters) tall. It has pink, purple, or white flowers that appear three or four weeks after the plant starts to grow aboveground.

The flowers of potato plants develop seedballs that resemble small green tomatoes. Each seedball contains about 300 yellowish seeds. Scientists use these seeds in developing new varieties of potato plants.

WORLD BOOK illustration by James Teason

A potato plant has leafy stems and pink, purple, or white flowers. From 3 to 20 growths called *tubers* form underground on the stems. The tubers are the edible parts of the plant.

WORLD BOOK illustration by James Teason

A cross section of a potato shows several layers of material. Each layer serves a function essential to the proper growth of the plant. Stems sprout from the eye of a tuber.

Growing potatoes

Planting and cultivating. Potatoes must be replanted annually because the plants die after the tubers mature. Potato plants grow best in areas where the temperature usually ranges from 60 to 70 °F (16 to 21 °C).

In the United States, potatoes are grown commercially in nearly every state. Farmers in the Southern States generally plant potatoes from September through March. In such Midwestern States as Kansas and Missouri, potatoes usually are planted in March, April, and May. In the Northern States, farmers plant potatoes in late spring and early summer. The tubers mature in 90 to 120 days, depending on the variety.

Most potato growers plant small, whole tubers and segments called *seedpieces,* which weigh about 1 ½ ounces (42 grams) and are cut from tubers. The whole tubers and the seedpieces are both known as *seed potatoes.* Each seed potato has at least one *eye* (bud) from which the stems grow both above and below the ground. Whole tubers are the best seed potatoes because they are less likely to rot and become diseased than seedpieces. Before planting seed potatoes, farmers spray them with fungicides to reduce the possibility of disease.

Commercial potato growers use machines that plant up to six rows of seed potatoes at a time. The seed potatoes are planted from 2 to 4 inches (5 to 10 centimeters) deep and 6 to 20 inches (15 to 51 centimeters) apart. The rows are planted from 30 to 36 inches (76 to 91 centimeters) apart. Potato growers plant 20 to 30 bushels of seed potatoes per acre (49 to 74 bushels per hectare).

Potatoes grow best in *loam,* a type of soil whose tex-

Lockwood Corporation

A potato combine digs up potato plants and separates the tubers from the soil. The potatoes are loaded automatically into a truck and taken to a packing shed. Then they are washed and packed for shipment or stored in warehouses.

ture varies between that of clay soil and sandy soil. The loam should be *aerated* (mixed with air), well-drained, and enriched with fertilizer. Farmers occasionally cultivate the soil around the growing plants. Cultivation helps aerate the soil, kill weeds, and supply soil covering for the growing tubers. Potato growers use two basic methods of cultivation, *ridge,* or *hill, culture* and *level culture.*

Ridge culture is the most common method of cultivation. Farmers use a cultivator to build small hills over the seed potatoes. The hills, which stand from 6 to 8 inches (15 to 20 centimeters) high, protect the tubers from sunburn or frost.

Level culture is used mostly in areas where growers plant the seed potatoes deep in the soil. They are planted in a deep furrow, which the farmer gradually fills as the plants grow.

After the flowers drop off a potato plant, some farmers spray the leaves frequently with chemicals to prevent the tubers from sprouting after being harvested. In certain areas, particularly in the Northern States, farmers sometimes destroy the leaves before the plants reach maturity. The farmers do this so they can harvest the potatoes before frost or disease hits the plants.

Harvesting. Most commercial potato growers use potato combines to harvest their crop. These machines dig the plants out of the ground, separate the tubers from the soil, and load the potatoes into trucks. The combines dig up two to four rows at a time.

The potatoes are collected and then taken to a packing shed to be washed and packed for shipment. Bruised or diseased potatoes are discarded, and the rest are graded according to size. Some potatoes are shipped directly to food-processing plants or supermarkets. But most potatoes are stored in warehouses at temperatures ranging from 40 to 50 °F (4 to 10 °C). The stored potatoes can be marketed as long as a year after being harvested.

Diseases and insect pests. Several diseases may attack potato crops. They include such fungus and bacterial diseases as *late blight, rhizoctonia, ring rot,* and *scab* and such virus conditions as *leafroll, mosaic,* and *spindle tuber.*

Late blight is controlled by spraying or dusting the plants with certain fungicides. Rhizoctonia and scab may be partially controlled by planting healthy seed potatoes. Ring rot can be controlled only by the use of disease-free seed potatoes. Virus diseases are best controlled by removing any diseased plants or tubers from the field and by using healthy seed potatoes.

The chief insects that attack potato plants include *aphids, flea beetles, leafhoppers, potato beetles,* and *potato psyllids.* The tubers are attacked by various insects, including *cutworms, grubs, potato tuber worms,* and *wireworms.*

Insects that feed on potato plants can be controlled by spraying insecticides into the furrow at planting time. The roots absorb the insecticides and transport them to the stems and leaves. The pesticides kill insects that feed on the leaves. Other insecticides may be sprayed directly on the leaves. Insects that attack tubers are controlled by spraying insecticides into the soil before planting.

History

The potato originated in South America. Botanists believe the white potato comes from a species that first grew in Bolivia, Chile, and Peru. Hundreds of years ago, the Inca Indians of those countries grew potatoes in the valleys of the Andes Mountains. From these potatoes, the Inca made a light, floury substance called *chuño.* They used chuño instead of wheat in baking bread.

Spanish explorers in South America were the first Europeans to eat potatoes. The Spaniards introduced them into Europe in the mid-1500's. About the same time, English explorers brought potatoes to England. From there, potatoes were introduced into Ireland and Scotland. They became the principal crop of Ireland because they grew so well there. In fact, the potato became known as the *Irish potato* because such a large part of the Irish population depended on it for food.

White potatoes were probably introduced into North America in the early 1600's. However, they did not become an important food crop until after Irish immigrants brought potatoes with them when they settled in Londonderry, New Hampshire, in 1719.

From 1845 to 1848, Ireland's potato crop failed because of late blight. Due to this and other factors, about 1 million Irish people died of disease or starvation. About 1 $\frac{1}{4}$ million others left Ireland and settled in other countries, chiefly the United States. Since the 1980's, new strains of late blight have reduced potato harvests throughout the world.

During the 1900's, the development of food processing has resulted in a tremendous use of potatoes in making such products as French fries and potato chips. Today, processing plants use about 80 percent of the potatoes grown in the United States. Hugh C. Price

Scientific classification. The white potato belongs to the nightshade family, Solanaceae. It is *Solanum tuberosum.*

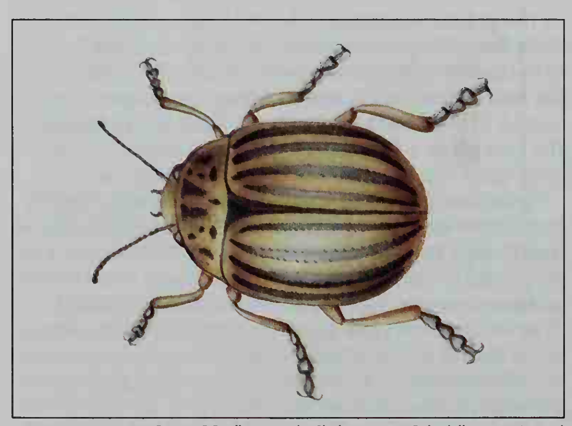
Burbank, Luther	Potato beetle	Sweet potato
Fungicide	Solanum	Tuber
Nightshade	Starch	



Potato beetle is the name of a group of beetles that attack potato plants. The beetles damage potato plants by feeding on the leaves and stems, and by transmitting such diseases as spindle tuber and root rot. The best-known species is the *Colorado potato beetle,* which probably originated in Mexico. When potatoes were first grown in the western United States, the beetle spread from its original food plant, the buffalo bur, to the potato plant. It is now found throughout the United States and parts of Canada.

Adult Colorado potato beetles measure about $\frac{1}{2}$ inch (13 millimeters) long. They are plump and yellow and have five black stripes on each wing cover. Adult beetles lay yellow eggs in clusters on the undersides of potato leaves. Larvae that hatch from the eggs are soft and orange-red in color. They feed on the leaves for about three weeks, then drop from the plant and burrow into the ground to become *pupae* (see **Pupa**). About 10 days later, the adults emerge. Two or three generations of beetles may be produced in one year.

The Colorado potato beetle is a difficult pest to control. A variety of insecticides have been used, but the beetles have gradually developed resistance to most of these chemicals. Enemies of the Colorado potato beetle include stinkbugs, toads, snakes, and birds.

John R. Meyer

Scientific classification. Potato beetles belong to the leaf beetle family, Chrysomelidae, in the order Coleoptera. The Colorado potato beetle is *Leptinotarsa decemlineata.*

The Colorado potato beetle deposits its eggs on potato plants. The larvae then feed on the tender leaves, damaging the plant, as shown in the photograph. Potato beetles are found in nearly every state.

Potato famine. See Ireland (The potato famine).

Potawatomi Indians, *PAHT uh WAHT uh mee,* belonged to the Algonquian language group of eastern forest tribes. They were closely allied with the Chippewa and Ottawa. These three tribes formed a confederacy known as "the three fires." In early days, the Potawatomi lived near the northern shores of Lake Michigan, from the eastern end of Lake Superior to Green Bay, Wisconsin, and in other areas around Lake Michigan. By 1700, groups of Potawatomi had moved into the Chicago and Detroit areas. Major groups lived along the St. Joseph River in Michigan and Indiana.

The Potawatomi raised corn, made maple sugar, and hunted buffaloes. They lived in dome-shaped lodges covered with bark. Early travelers described the Potawatomi as being polite and more civilized than other tribes of the area. Many Potawatomi became Christians.

The Potawatomi sided with the French until the end of the French and Indian wars. They took a prominent part in the Indian rebellion under Pontiac (see **Indian wars** [Along the frontier]; **Pontiac**). They fought with the British against the Americans in the Revolutionary War and the War of 1812. A group of Potawatomi and their Chippewa and Ottawa allies ambushed the retreating garrison of Fort Dearborn in Chicago in August 1812 (see **Fort Dearborn**). After the war, these Indians became friendly with American settlers. In the 1830's, the U.S. government moved the three tribes from their lands in Illinois to regions west of the Mississippi River. The tribes were the last Indians to leave Illinois.

Today, Potawatomi live throughout the United States, but mainly in Wisconsin, Indiana, Michigan, Oklahoma, and Kansas. Potawatomi also live in Ontario, Canada, and in several other countries. Francis Levier

Potomac River, *puh TOH muhk,* is a beautiful and historic stream that forms the boundary between Maryland, West Virginia, and Virginia. It winds 287 miles (462 kilometers) in a southeast course from its source in the Allegheny Mountains to its mouth in the Chesapeake Bay (see **Virginia** [political map]). Large ships can sail inland for 115 miles (185 kilometers) to Washington, D.C. The Potomac is from 2 to 7 miles (3 to 11 kilometers) wide for its last 100 miles (160 kilometers). It drains an area of 14,500 square miles (37,550 square kilometers).

The historic Potomac breaks through the Blue Ridge Mountains at Harpers Ferry, the scene of John Brown's Raid. The river also flows past Mount Vernon, the home of George Washington. Michael P. O'Neill

Potsdam (pop. 138,737) is a German city that stands on the Havel River, about 15 miles (24 kilometers) southwest of Berlin. For the location of Potsdam, see **Germany** (political map).

Potsdam's leading economic activities include engineering and the production of chemicals, processed foods, and textiles. Flower growing is also an important industry, especially the cultivation of winter violets. Broad squares and public gardens add to the city's beauty. John W. Boyer

See also **Potsdam Conference.**

Potsdam Conference was the last meeting among the leaders of the United Kingdom, the Soviet Union, and the United States during World War II (1939-1945). It opened at Potsdam, Germany, near Berlin, on July 17, 1945, about two months after Germany's defeat in the war. Present at the opening were U.S. President Harry S. Truman, British Prime Minister Winston Churchill, and Soviet Premier Joseph Stalin. Clement Attlee succeeded Churchill as prime minister on July 26 and represented the United Kingdom for the rest of the conference, which ended on August 2.

Earlier agreements had divided Germany into British, French, Soviet, and U.S. occupation zones. At Potsdam, the participants agreed to treat the country as a whole in economic matters. The Soviet Union received a third of Germany's ships and some industrial equipment as payment for war damages. The participants also agreed to prosecute German leaders for war crimes (see **Nuremberg Trials**). While at Potsdam, Truman learned of the first successful atomic bomb test. That news led to the Potsdam Proclamation, threatening the destruction of Japan unless it stopped fighting the Allied nations and surrendered without conditions.

At Potsdam, the U.S. and British leaders charged that the Soviet Union had helped establish Communist governments in the countries of Eastern Europe that it had freed from German control. This criticism clearly showed a serious division among the members of the wartime alliance. Diane Shaver Clemens

Potter, Beatrix (1866-1943), was an English author and illustrator known for her charming children's stories about small animals. Her books combine stories of adventure and humor with delicate water colors that capture the action and mood of the text. Potter's first and most famous story is *The Tale of Peter Rabbit* (1902).

Potter wrote and illustrated about 25 books. In addition to Peter Rabbit, her characters include Squirrel Nutkin, Benjamin Bunny, Tom Kitten, Jemima Puddle-Duck, the Flopsy Bunnies, and Pigling Bland.

Helen Beatrix Potter was born on July 28, 1866, in London to wealthy parents. She began drawing plants and animals as a child. Potter based many of her illustrations on the animals and rural landscapes of the Lake District of northern England. Marilyn Fain Apseloff

Potter, Harry, is the boy hero of a spectacularly popular series of fantasy novels for children. The author is J. K. Rowling, an English writer.

Rowling introduced Harry in *Harry Potter and the Philosopher's Stone* (1997), her first published book. The novel became an immediate best seller in both the United Kingdom and the United States, where it was published in 1998 as *Harry Potter and the Sorcerer's Stone.* Also best sellers are *Harry Potter and the Chamber of Secrets* (1998), *Harry Potter and the Prisoner of Azkaban* (1999), and *Harry Potter and the Goblet of Fire* (2000). The motion-picture version of *Harry Potter and the Sorcerer's Stone* (2001) set box-office records.

The Harry Potter series is unique in publishing because of its widespread popularity among both adults and young people. Some literary critics proclaim the novels to be classics of children's literature.

Harry Potter begins the series as an 11-year-old boy. He grows one year older in each succeeding book. Rowling plans the series to run to seven novels.

After the wicked sorcerer Lord Voldemort murders Harry's parents, the orphaned boy is raised by his nasty Aunt Petunia and Uncle Vernon Dursley. Harry learns he is a wizard and is invited to attend the Hogwarts School of Witchcraft and Wizardry to study magic skills. He survives one danger after another, accompanied by his friends Ron and Hermione. Their adventures include encounters with a magical flying car, ghosts, giants, magic spells, and hostile classmates and teachers. All the stories mix suspense with humor. Zena Sutherland

Potter's field is a free burial ground for strangers, criminals, and people too poor to pay funeral expenses. The Bible tells of the first plot of ground known as a potter's field. After Judas Iscariot betrayed Jesus Christ to the high priests of Jerusalem for 30 pieces of silver, he returned the money to the priests. They would not use the money for their Temple. Instead they bought "the potter's field to bury strangers in" (Matthew 27:7). Scholars believe this field was in the Valley of Hinnom, near Jerusalem. The term *potter's field* was widely used in the United States during the 1800's. Richard A. Kalish

Pottery is a type of decorative or useful ware made of baked clay. It ranges from valuable works of art to dinnerware, vases, and other simple household items. The word *pottery* also means a factory that makes pottery.

A piece of pottery may be mass-produced, or it may be the only one of its kind. Since ancient times, potters

have shaped and *fired* (baked) clay to make pottery. Some pottery in museums is thousands of years old and still in good condition.

Pottery belongs to a large group of items called *ceramic products.* Such products are made from materials known as *ceramics.* Ceramic products, in addition to pottery, include bricks, cement, grinding tools, sewer pipes, and other products used in industry. For more information on the products and processes of the ceramics industry, see the *World Book* article on **Ceramics.**

Types of pottery

The three major types of pottery are (1) earthenware, (2) stoneware, and (3) porcelain. Pottery is classified according to the mixture of clays that it contains and the temperature at which the mixture is fired. The firing temperature affects both appearance and strength.

Earthenware is a widely used type of pottery made largely from a mixture of earthenware clays. Such clays are found in soil in all parts of the world. Many people prefer earthenware because of the colorful *glaze* (glassy coating) which is applied to it. This pottery, like most bright, colorful glazes, is baked at a low temperature. Other types of pottery are less colorful because they are fired at a high temperature that harms most colorful glazes. Earthenware breaks and chips more easily than other types of pottery.

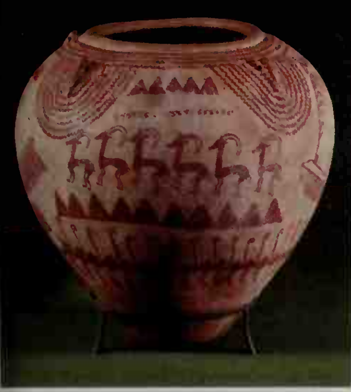
Stoneware is a hard, heavy kind of pottery made mostly from a mixture of stoneware clays. These clays are found in the soil of scattered areas of the United States. Potters fire such clays at extremely high temperatures. The heat causes the surface of stoneware to become glossy, and so many potters do not glaze it. Stoneware is stronger and heavier than earthenware. Like earthenware and some kinds of porcelain, it is *opaque*—that is, light cannot shine through it.

Porcelain is the purest and the most delicate type of pottery. There are two types of porcelain. *Hard paste porcelain* is fired at high temperatures. *Soft paste porcelain,* which includes chinaware, is fired at lower temperatures.

Potters make porcelain from a mixture that includes flint, a mineral called *feldspar,* and large amounts of kaolin. Kaolin is a fine, white clay, and so most porcelain fires to a delicate shade of white. Light can shine through a thin piece of porcelain. See **Kaolin.**

How pottery is made

There are four basic steps in making pottery: (1) preparing the clay, (2) shaping the clay, (3) decorating and glazing, and (4) firing.



Preparing the clay. Potters prepare clay by pressing and squeezing it with their hands or by mechanical methods. This treatment makes clay soft and smooth, and it eliminates air bubbles that could cause the clay to crack during the firing process.

Shaping the clay can be done by various methods. Some of these methods involve *hand building,* in which potters use only their hands to shape the clay. The easiest hand-building method consists of pinching the clay into the desired form. Many beginning potters use this process to make small bowls called *pinch pots.* Another method of hand building, called *solid forming,* consists of shaping a sculpture out of a lump of clay.

The most common ways of shaping clay include (1) the coil method, (2) the slab method, (3) the mold method, and (4) the wheel method. The first two methods involve hand building, and the second two require equipment. A potter may use a combination of these methods. For example, the potter might form the body of a teapot on a potter's wheel and use a hand-building method to make the handle and spout.

The coil method is one of the oldest and simplest ways of making pottery. After preparing the clay, the potter shapes part of it into a flat piece that will be the base of the ware. The remaining clay is rolled into long strips. Using the base piece as a foundation, the potter coils the strips of clay on top of one another.

The coils must be attached together to make the pottery strong. The potter attaches each coil layer to the

ꞏxt with a creamy substance called *slip.* Slip, which ꞏrves as a cement, is made by adding water to clay. Potꞏrs always smooth the inside surface of a piece of coil ꞏttery. They may also smooth the outside surface, deꞏnding on the design of the piece.

The slab method forms pottery from flat pieces of ꞏay. The potter shapes the clay into flat slabs by poundꞏg it with the fists or by flattening it with a rolling pin. ꞏsing one slab as the base, the potter places other slabs ꞏright angles to it to form the sides of a piece of potꞏry. The slabs are then attached together with slip. ꞏabs may be difficult to work with, especially if they are ꞏge. For this reason, the potter may let the slabs ꞏrden slightly before fastening them together.

The mold method is used to produce identical pieces ꞏpottery. One technique of mold shaping, called *slip casting,* is used to turn out a large number of pieces of hollow pottery. In slip casting, the potter pours slip into a mold and lets part of it dry. The slip nearest the sides of the mold thickens quickly. After a few minutes, the slip in the middle of the mold is poured out, leaving the thicker slip attached to the sides. The thick slip dries into a finished piece of pottery.

Mold shaping can also be done by *jiggering.* Jiggering involves a device called a *jigger,* which consists of two pieces of plaster that form a mold. The potter puts the clay between the two pieces of plaster and, by pressing them together, squeezes the clay into the desired shape.

The wheel method involves the use of a *potter's wheel.* This device consists of a round, flat, metal surface that turns while the potter shapes clay on it.

Most wheels are electrically powered and turn when the potter presses a foot pedal.

As the wheel turns, the potter pushes the thumbs or other fingers into the center of the spinning clay. This action forms the clay into a pot that has low, thick sides. The potter shapes the sides into the desired form by pressing one hand on the inside and one hand on the outside of the spinning pot.

Decorating and glazing. Potters can put simple decorations on their ware by pressing their fingers into the soft clay or by scratching lines into it. Elaborate designs can be drawn on pottery by using colored substances that will not be damaged by heat during firing. Such substances include enamel, glaze, and slip.

One type of pottery decoration is called *sgraffito.* In this method, the potter puts a thin layer of colored substance on a piece of pottery of a different color. The potter then uses a sharp tool to scratch through the colored outer layer, allowing the color of the clay body to form a design in the actual surface of the pottery beneath. Potters can make attractive decorations by filling in the sgraffito grooves with substances of various colors.

Glazing is used not only to decorate, but also to smoothen and waterproof pottery. Potters have developed many types and colors of glaze. They apply it in several ways, including brushing, pouring, or spraying it onto pottery. After a piece of pottery is glazed, the potter fires it. Some types of pottery must be fired before being glazed. After glazing, they are fired again to bake the glaze. A few kinds of pottery are usually not glazed. They include a stoneware called *jasper* and an earthenware called *terra cotta* (see **Terra cotta**).

Firing makes pottery hard and strong. It also makes glaze stick to clay, and it hardens the glaze as well. Pottery is fired in an oven called a *kiln.*

History

Early pottery consisted of simple household utensils. People in several parts of the world were making pottery by about 11,000 B.C. The Egyptians, about 3000 B.C., became the first people to glaze pottery. Pottery making spread from Egypt and the Near East to the areas around the Mediterranean Sea.

By about 1600 B.C., people on the island of Crete were producing beautiful pottery decorated with curved designs and pictures of animals. Cretan methods of making and decorating pottery influenced Greek ware. The ancient Greeks made graceful pottery and decorated it with vivid designs.

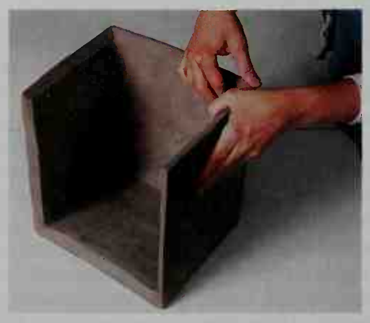
Peoples in other parts of the world also developed pottery skills. In North and South America, many Indian tribes developed the art of making pottery. Tribes that created especially beautiful pottery included the Inca, the Maya, and the Pueblo.

In Africa, potters in the kingdom of Nok developed an advanced pottery style by about 500 B.C. They specialized in making decorative pottery in the form of realistic human heads. Between about A.D. 600 and 950, artists in the African kingdoms of Ife and Benin used sculptured pottery figures as models for large, metal statues.

In China, potters had started to use the pottery wheel during the Shang dynasty (c. 1500-1027 B.C.). Chinese potters learned to make porcelain, probably during the Tang dynasty (A.D. 618-907). Potters of the Song dynasty (A.D. 960-1279) experimented with many pottery shapes and glazes. They created some of the loveliest pottery in history.

About 1200, the Chinese began to export pottery to the countries of the Near East. The potters of these nations combined Chinese styles with their own and developed new forms and designs. One of the new forms resulted in a type of colorfully glazed pottery called *majolica* (see **Majolica**).

Pottery of the 1700's and 1800's featured developments in Europe and the New World. The nations of the Near East began to export much of their pottery, including majolica, to Europe. European pottery-making centers, especially in Italy, copied the Near Eastern pottery. The European centers introduced new styles of their own as well, including types of majolica called *delft* and *faïence* (see **Delft; Faïence**).



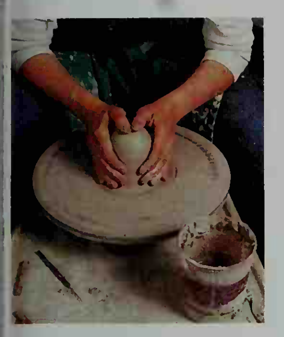
In 1708, Johann Friedrich Böttger, a German chemist,

How pottery is made

First, the potter selects and prepares the clay. The potter shapes it, using one of several methods. Three common methods are described below. After the clay dries, the potter may coat it with a smooth glaze. Finally, the potter bakes the pottery in an oven to harden it.

The coil method involves cutting out a bottom and then rolling ropes of clay and stacking them. The potter then may smooth the layers together.

The slab method. The potter first cuts the clay into slabs and then fastens the slabs to one another with creamy clay called *slip.*

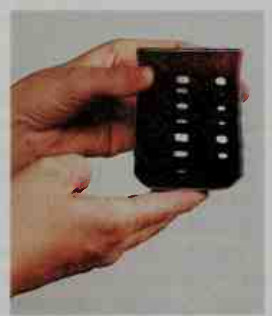


WORLD BOOK photos by Odyssey Productions

The mold method. Slip is poured into a mold. After the slip next to the mold hardens, the extra slip is poured out. The mold is split, and the piece is removed.

Making pottery on a potter's wheel

Since early times, people have made vessels by using a potter's wheel. The wheel consists of a revolving disk mounted on a spindle. The potter spins the disk by using a foot control or mechanical power. Various hand and finger movements are used to mold the clay into the desired shape.



A lump of clay is spun on a wheel. The potter smooths it and pokes both thumbs into the top to make it hollow.

The sides of the vessel are shaped by drawing up the clay. The potter locks thumbs to steady the hands.

Excess clay is trimmed off with a tool. Then the potter removes the finished vessel with a wire or a knife.

WORLD BOOK photos by Odyssey Productions

Finished pottery is given color, smoothness, and extra toughness by being glazed and fired in an oven.

became the first European to discover how to make porcelain. The Chinese had refused to share the secret of porcelain making. After European industrialists established factories to make porcelain, they also kept the method of porcelain making a secret. Many European wares greatly influenced pottery making. These respected wares included Meissen, Sèvres, Wedgwood, and Worcester.

When Europeans settled in the New World, they brought their own styles of pottery making. Later, pottery in the United States followed European styles until 1880. That year, Maria Longworth Nichols, better known by her married name of Mrs. Bellamy Storer, a potter in Cincinnati, Ohio, founded the Rookwood Pottery to produce art pottery. This plant produced pottery that reflected local ideas and tastes. Most of the Rookwood pottery that was produced had colorful glazes and many types of decoration.

Modern styles of pottery developed during the 1900's. These styles resulted from the desire of potters to create individual, personal ware. Today, most studio potters use methods of shaping and decorating that were used before the Industrial Revolution of the 1700's and 1800's. Developments in pottery design that take place in one part of the world quickly reach and influence potters in other regions.

Since the early 1900's, people in many parts of the world have developed an interest in pottery making as a hobby. Amateur potters can go to specialized schools and pottery studios to learn the craft. Exhibitions encourage amateur and professional potters to show their wares and to exchange ideas. William C. Gates, Jr.

Poulenc, *poo LANK,* **Francis,** *frahn SEES* (1899-1963), was a French composer and pianist. He was particularly noted for his vocal music, which features beautiful melodies and great sensitivity to words. Poulenc's songs and song cycles are among the most important solo vocal works of the 1900's.

Poulenc, a devout Roman Catholic, wrote several major religious works, including his *Mass in G* (1937), *Stabat Mater* (1950), and *Gloria* (1959). He also wrote the religious opera *The Dialogues of the Carmelites* (1957) and a one-act tragedy for soprano, *The Human Voice* (1959). Poulenc was a fine pianist and developed a highly personal composing style in such works as *Trois mouvements perpétuels* (1918).

Poulenc was born in Paris. In the early 1920's, he became a member of a group of six French composers known as *Les Six.* Daniel T. Politoske

Poultry are birds that are raised to provide meat and eggs for human food. Chickens are by far the most common kind of poultry raised throughout the world. Other important species include turkeys, ducks, geese, guinea fowl, pheasants, pigeons, and quail. Some birds are particularly prized by certain peoples. For example, guinea fowl are an important species in France.

Although poultry are used primarily for food, they also provide several important by-products. Manufacturers use the feathers of ducks and geese to stuff pillows and insulated clothing. Farmers use poultry manure as fertilizer. Eggs are used not only as food but also in making paint, vaccines, and other products.

Chickens, ducks, and turkeys are the most common kinds of poultry raised in the United States and Canada. In the late 1990's, U.S. farmers earned about $22 billion a year from the sale of poultry meat and eggs. Canadian farmers earned about $1.4 billion (in U.S. dollars) annually from poultry and eggs.

People in the United States consume an average of 65 pounds (29 kilograms) of poultry yearly. About 80 percent of the poultry consumed comes from chickens. The rest comes mainly from turkeys. Canadians eat an average of 61 pounds (28 kilograms) of poultry a year. People in the United States eat an average of about 240 eggs each per year. Canadians average 235 eggs annually. Almost all the eggs eaten in Canada and the United States are chicken eggs. People in some other countries also eat the eggs of ducks, geese, and other fowl.

California, Indiana, Iowa, Ohio, and Pennsylvania lead the United States in egg production. Leading producers of chickens for use as meat include Alabama, Arkansas, and Georgia. Minnesota and North Carolina are the chief turkey-producing states. Other leading producers include Arkansas, California, Missouri, and Virginia. Long Island produces about a fourth of the ducks in the United States. Ontario and Quebec produce the majority of the poultry products in Canada.

A large poultry house holds thousands of chickens. Mechanical equipment brings feed and water to the birds automatically.

Raising poultry. Most of the poultry produced in the United States comes from large commercial farms that raise only these birds. Some of the farms have flocks of more than a million birds. A small percentage of U.S. poultry is raised in flocks that consist of 5,000 or fewer birds. Many small poultry farmers also do other kinds of farming. Most commercial poultry farmers buy baby birds from hatcheries, which hatch eggs in incubators.

Female chickens raised to produce eggs are called *laying hens.* They begin to lay eggs when they are about 21 weeks old. The birds are kept in long, low buildings called *laying houses,* each of which may hold as many as 50,000 hens. In many of these houses, the hens live in cages that have a sloped floor so the eggs can roll out. In highly automated laying houses, mechanical devices carry feed and water to the hens, and a conveyor belt carries the eggs to a central collecting room. The hens are kept in the laying house for about 12 months after they start to lay eggs. Then they are either kept in laying houses for another season, or are sold for slaughter and replaced with young birds.

Chickens raised only for their meat are called *broilers* or *fryers.* Most broilers are raised indoors on a dirt or concrete floor that is covered with *litter.* Litter is straw, wood shavings, or some other material that absorbs moisture, keeping the birds clean. Broilers eat and drink from automatic feeders and water containers.

Geese, turkeys, and some other birds require more space because they are larger than chickens. Most of these birds are raised outdoors in pens or fenced fields. However, many turkey farmers raise their birds indoors. Most ducks are also raised indoors. Pheasants, quail, and other birds are cared for much as broilers are, but most farmers raise them in smaller flocks.

Poultry feed consists of a mixture of ingredients that promotes rapid growth or high egg production. The main ingredient is corn, wheat, sorghum, or some other

grain. The grain is mixed with protein supplements, such as soybean meal or meat by-products. Vitamins and minerals are also added. A broiler eats an average of 1 pound (0.45 kilogram) of feed per week. A laying hen consumes about 4 pounds (1.8 kilograms) of feed for every dozen eggs that she lays.

Diseases and parasites are a major problem of poultry farmers. Many birds are kept in a small area, and so disease can spread quickly through a flock. Farmers vaccinate their birds, add drugs to the water or feed, and keep the flocks clean. Respiratory ailments of poultry include *Newcastle disease, infectious bronchitis,* and *laryngotracheitis. Marek's disease* and *leukosis,* which kill many birds, result from tumors caused by viruses. Parasites cause a disease called *coccidiosis.*

Breeding is another important aspect of poultry raising. Breeders have developed types of birds that produce more meat or eggs than other types. For example, turkeys raised in the United States have an extremely broad breast that yields much white meat.

Marketing poultry and eggs. Poultry raised for meat are marketed at various weights and ages. For example, broilers reach a market weight of about 4 pounds (1.8 kilograms) when they are about 8 weeks old. Turkey market weights vary widely, depending on type. A typical hen turkey reaches its market weight of about 15 pounds (6.8 kilograms) at 15 weeks old. Tom turkeys weigh about 24 pounds (11 kilograms) at 17 weeks. Ducks are ready for market when they are 7 or 8 weeks old and weigh approximately 6 pounds (2.7 kilograms).

Market-size poultry are sent to processing plants to be slaughtered, inspected, and graded. Then they are sent to supermarkets. More than 90 percent of the broilers sold in the United States and Canada are sold fresh. About 70 percent of the turkeys are processed and sold as specialty meat. Most whole turkeys are sold frozen, chiefly at Thanksgiving and Christmas. About 40 percent of ducks and geese are sold frozen.

Egg farmers generally sell their eggs directly to supermarkets or to wholesalers. Most eggs are sold to consumers fresh, though some are used in such processed food items as cake mixes and noodles. Eggs must be washed, graded, and packed in cartons to prepare them for marketing. Inspectors determine the quality of the interior of an egg by *candling.* This technique involves examination of the egg while shining a strong light through it from behind. Eggs are stored and shipped under refrigeration to ensure their freshness.

During the 1970's, the poultry industry developed several new kinds of processed meats from poultry. These meats included "frankfurters" made of chicken and "ham" made of smoked turkey. The poultry meats were generally cheaper and less fatty than the products made from beef or pork. N. Paul Johnston

Pound, also called *pound sterling,* is the monetary unit of the United Kingdom and some other countries. The British pound (£) is equal to 100 pence (*p*). There are paper bills for £5, £10, £20, and £50. In 1983, the British government introduced a one-pound coin to replace the one-pound note, which it stopped issuing on Dec. 31, 1984. In 1999, the government began issuing a five-pound coin.

WORLD BOOK photo

A British one-pound coin has a picture of Queen Elizabeth II on the front and a symbol of the United Kingdom on the back.

Until 1931, the government had made for circulation one-pound gold coins called *sovereigns.* Sovereigns were first made in 1489. Later, the sovereign was called a *unite,* in honor of the joining of England and Scotland under James I, who became king of both nations in 1603. George III chose the sovereign as the monetary unit, and it was first issued regularly in 1817. Half sovereign, two-pound, and five-pound pieces were also coined. Sovereigns and other gold coins are now used for dealings with nations that require payment in gold.

The British pound is often used as an international form of money to settle debts between nations. But gold and United States dollars are the most widely accepted forms of international money. Burton H. Hobson

Pound is a unit of weight used primarily in the United States. In science and technology, *weight* refers to the gravitational force on an object, and the pound is used as a unit of force. This unit also appears in the term *pounds per square inch* (psi), which is used as a measure of pressure. In commercial and everyday use, the term *weight* is understood to mean *mass* (quantity of matter), and so the pound is also used as a unit of mass.

In the system of weights called the *avoirdupois (AV uhr duh POYZ) system,* which is used to weigh most objects, there are 16 ounces to a pound. As a unit of force, the avoirdupois pound is equivalent to 4.448 newtons in the metric system; as a unit of mass, 0.454 kilogram in the metric system. In the troy weight system, used throughout the world to measure precious metals, a pound equals 12 ounces and is equivalent to 0.373 kilogram.

The abbreviation for pound is *lb.* The abbreviation stands for the Latin word *libra,* which means *pound* or *balance.* Libra was the name of a unit of weight used by the ancient Romans, and it was the name for a balance, or scale, that Romans used to measure weight. The symbol # is sometimes used for pound. Michael Dine

Pound, Ezra Loomis (1885-1972), was an American poet and essayist. He became one of the most influential and controversial literary figures of the 1900's.

Disillusioned with what he considered the artistic backwardness of the United States, Pound left the country in 1908. He lived in Venice, London, Paris, and, finally, Rapallo, Italy. He became the friend and critic of Irish writers William Butler Yeats and James Joyce.

Pound also helped such then-unknown poets as T. S. Eliot, William Carlos Williams, and Robert Frost.

Pound's early work reflects his conviction that the poet must play a vital role in the culture of the time. In his poem "Hugh Selwyn Mauberley" (1920), Pound revealed his anger at the slaughter during World War I (1914-1918) and his despairing sense of the failure of art to affect the course of history.

Pound spent the last 50 years of his life composing a never-completed, 800-page poem called *The Cantos.* In the first section, Pound traced the rise and fall of Western and Eastern civilizations, emphasizing the conflict between artistic spirit and materialistic greed. The *Cantos* that were written during the late 1920's and the 1930's deal with the economic and political corruption Pound saw developing since the time of two of his heroes, John Adams and Thomas Jefferson.

Pound's indignation rapidly turned to anti-Americanism and anti-Semitism. Pound became an admirer of the Fascist rule of Italian dictator Benito Mussolini. During World War II (1939-1945), Pound broadcast Fascist propaganda to the United States. In 1945, the U.S. government arrested Pound for treason. While imprisoned at a U.S. Army camp in Pisa, Italy, Pound wrote some of his most moving and self-critical verses, the *Pisan Cantos.* In 1946, Pound was judged insane and spent 12 years in a Washington, D.C., mental hospital. He was released in 1958 and returned to Italy.

Pound was born in Hailey, Idaho. An edition of *The Cantos* was published in 1970. His criticism was collected in *Literary Essays of Ezra Pound* (1954) and *Selected Prose 1909-1965* (1973). Steven Gould Axelrod

Pound, Roscoe (1870-1964), was an American educator and authority on law. He introduced to the United States a view of the nature and purpose of law which came to be known as "sociological jurisprudence." This view treats law as a system of social engineering.

Pound wrote widely on legal history, legal philosophy, and law reform. He became one of the best-known figures in American legal education. His books include *The Spirit of the Common Law* (1921), *Law and Morals* (1924), *The Formative Era of American Law* (1938), and *Social Control Through Law* (1942). Pound was born in Lincoln, Nebraska, and graduated from Harvard Law School. He became a professor of law at Harvard in 1910, and served as dean of the Harvard Law School from 1916 to 1936. David M. O'Brien

Poundmaker (1826-1886), a Cree Indian chief, led a band of warriors against the Canadian government during the North West Rebellion in 1885 (see **North West Rebellion**). The Cree had been suffering from shortages of food. They joined the uprising because they felt the government had done little to help them solve this and other problems.

The Public Archives of Canada
Poundmaker

In March 1885, Poundmaker's band raided Battleford, in what is now Saskatchewan. In May, Indians led by Poundmaker defeated Canadian troops in the Battle of Cut Knife Hill. The Cree chief later surrendered after learning that the forces of Louis Riel, the leader of the rebellion, had been defeated. Poundmaker was sentenced to three years in prison. He served only six months and died shortly after his release. He was born near what is now Edmonton, Alta. His Indian name was Opeteca-hanawaywin.

Hartwell Bowsfield

Poussin, *poo SAN,* **Nicolas,** *nee kaw LAH* (1594-1665), was the most highly respected French painter of his age. Poussin believed that painting should appeal to the mind more than to the senses. His works are meant to be read from figure to figure and incident to incident, and to be brought together as a whole in the viewer's mind. He believed an artist should choose as subjects only the noblest human actions, and he took almost all his subjects from mythology and from the Bible.

Saint Matthew and the Angel (about 1643), an oil painting on canvas; Staatliche Museum, Berlin

A Poussin painting shows the harmony and clarity typical of the artist's classical style. The figures of Saint Matthew and an angel reflect Poussin's interest in religious themes.

Like many painters of the mid-1600's, Poussin believed that drawing was a more important foundation of painting than color. The clarity of Poussin's forms reflects this belief. However, for all of Poussin's sober forms and clarity of color, his paintings, especially his religious works, show deeply felt emotion.

Poussin was born in or near Les Andelys, near Rouen. He went to Paris at the age of 18 to become a painter, but he did not develop his own style and gain success until he traveled to Italy 12 years later. He lived in Rome nearly all of the rest of his life. He was supported by aristocratic patrons, and he held the position of First Painter to the king of France. Ann Friedman

For examples of Poussin's work, see **Painting** (The 1600's and 1700's) and **Mythology** (How myths began). See also **Classicism** (The qualities of classicism).

Poutrincourt, *poo tran KOOR,* **Jean de Biencourt de** (1557-1615), Baron de St. Just, a French colonizer, helped found Acadia, a region in eastern Canada and northern Maine (see **Acadia**). He went to Canada in 1604 with Sieur de Monts (see **Monts, Sieur de**). Poutrincourt received a grant of land and established a colony at Port

Royal. In 1606, he accompanied Samuel de Champlain in his exploration of the Bay of Fundy. In 1607, Poutrincourt went back to France. He returned to Acadia in 1610 and lived at Port Royal until 1613, when English settlers from Virginia destroyed most of the settlement. He then went back to France. His son Charles de Biencourt de Saint-Just stayed in the colony and traded with the Indians. Poutrincourt was born in Picardy, France.

John A. Dickinson

Poverty is the lack of enough income and resources to live adequately by community standards. These standards—and the definition of poverty—vary according to place and time. For example, many people who live in the United States today believe they must have an automobile to live decently. Such people would consider themselves poor if they could not afford one. However, people who live in some nonindustrial countries regard cars as luxuries. They would not consider the lack of a car a sign of poverty.

Poverty causes suffering among millions of people. Many of the poor cannot buy the food, shelter, clothing, and medical care that they need. Neediness causes malnutrition and poor health. It also produces feelings of frustration, hopelessness, and a loss of dignity and self-respect. Governments and private organizations have tried to reduce or eliminate poverty. But it remains a widespread and serious world problem.

Who are the poor?

The different definitions of poverty from country to country make it difficult to determine how many people are poor. It is estimated that more than 1 billion people, about a fifth of the world's population, are so poor that their health and lives are endangered. The most widespread and severe poverty occurs in nations with few resources. These nations are sometimes called *developing nations.* This article will deal mainly with poverty in the United States and other highly industrialized nations. For information on poverty in other countries, see **Developing country.**

Measuring poverty. The U.S. government measures poverty according to yearly income. The government identifies as poor those households whose incomes fall at or below a certain level called the *poverty level* or *poverty line.* The poverty line is based on the income that households need to eat adequately without spending more than a third of their income on food. The U.S. government revises the poverty line each year to keep up with changes in the cost of living.

The government varies the poverty line according to household size. In addition, it varies the poverty line for one- and two-person households of people 65 and older. For the poverty line for families of various sizes, see the table "Poverty in the United States" that appears in this article.

The distribution and rate of U.S. poverty. The U.S. government classifies approximately 14 percent of the population as poor. Some groups have poverty rates that exceed that of the general population. These groups include African Americans, Hispanic Americans, and families headed by single mothers. Groups with lower-than-average poverty rates include the elderly and two-parent families.

Many people are poor at some time in their lives. Most can raise their incomes above the poverty line within a few years. But many of the people who are poor are in the midst of a long period of poverty lasting a decade or more. Many poor people are homeless.

The poverty rate has gone alternately up and down in the United States since the 1960's. The rate tends to fall in times of strong economic growth and rise when the economy is weak. A number of other factors have put upward pressure on the poverty rate. They include a rise in the percentage of the population that lives in single-parent families. Such families have a much higher poverty rate than two-parent families. Also, some government social welfare programs have reduced the amount of assistance to the poor. In addition, the wages of many workers do not always rise as fast as prices.

Because the United States is such a prosperous country, a smaller percentage of its citizens lack basic necessities than the citizens of many other countries. But the poverty rate is higher in the United States than in several other industrialized nations, including Canada, Australia, and Germany. Such nations often have more generous social programs for the poor.

Effects of poverty

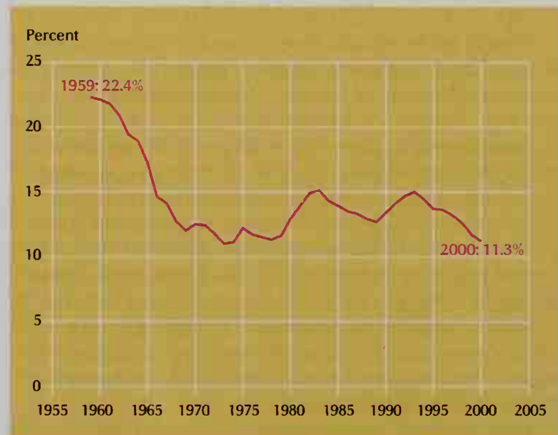
Effects on the poor. Poverty-stricken people suffer from the lack of many things they need. For example, they are less likely to receive adequate medical care or to eat the foods they need to stay healthy. The poor have more diseases, become more seriously ill, and die at a younger age than other people do. Poor people often live in substandard housing in socially isolated areas where most of their neighbors are poor. Many low-income families live in crowded, run-down buildings with inadequate heat and plumbing. The jobs most readily available to the poor provide low wages and little opportunity for advancement. Many of these jobs also involve dangerous or unhealthful working conditions. Financial, medical, and emotional problems often strain family ties among the poverty-stricken.

The poor have less economic and political influence than other people have. For example, businesses try to produce goods and services that many people will buy. Low-income consumers buy relatively little, and so they have relatively little influence on what businesses produce. The needy have little political power because few of them vote in elections.

Some social scientists call poverty a vicious circle or say that poverty breeds poverty. Studies show that some children born into low-income families remain poor for many years. Poor children often enter school with less preparation and less-developed language skills than other children do. They also often attend lower-quality schools and thus are less likely to go to college or get a good job. Public schools in the United States rely heavily on local property taxes. Low-income communities generate less tax money, and so they cannot afford the educational programs that wealthier communities have.

Some social scientists say the poor have a set of customs, values, and attitudes that are part of a *culture of poverty.* This culture tends to view educational and economic achievements as a product mostly of luck rather than hard work. Many social scientists consider this culture a result of the economic stresses that are associated with poverty. However, some social scientists believe

Poverty in the United States



This table shows the average poverty line for families of various sizes in 2000. For example, the government classified an average family of four persons as poor if its annual income was $17,603 or less. This table also shows the number of families at or below the poverty line for each level of family size.

Family size	Annual income	Number of families
1	$ 8,794*	8,529,000
2	11,239*	2,202,000
3	13,738	1,428,000
4	17,603	1,250,000
5	20,819	708,000
6	23,528	342,000
7	26,753	135,000
8	29,701	75,000
9 or more	35,060	81,000

*For persons 65 and older, the poverty line was $8,259 for a single person and $11,590 for a two-person family.

Poverty rate in the United States since 1959

The poverty rate is the percentage of people living at or below the poverty line. The Census Bureau began measuring the poverty rate in 1959.

Source: U.S. Census Bureau.

the culture also causes poverty. Both views are widely held by the public and lawmakers, which has caused disagreements over which policies are the best for reducing poverty.

Effects on society. Society is affected by poverty in a number of ways. For example, inadequate food, medical care, and education reduce the economic and social contributions of the poor. A person who is ill or poorly educated is less likely to become a productive worker or an active citizen. A significant portion of the revenue that state and federal governments collect through taxes pays for programs that assist the needy.

Poverty is also associated with crime. Urban slums, inhabited mainly by poor people, have high rates of violent crime and drug abuse. However, many of the needy do not commit crimes, and numerous nonpoor people do. As a result, many social scientists disagree about the extent to which poverty causes crime.

The causes of poverty

Poverty in the United States has a variety of causes. One major cause is that steady, well-paying jobs can be difficult to find and keep. Many people lack the education or skills needed for such jobs. Other people are too old or sick to work.

Economic forces and changes in labor requirements also cause poverty. For example, inflation contributes to poverty by reducing the amount of goods that a given amount of money can buy. People whose incomes fail to keep pace with prices can afford less and less. Economic downturns add to poverty by forcing businesses to lay off workers. Advances in technology may cause unemployment and poverty among workers whose jobs are taken over by machines. Poverty also may strike a particular community when a major business moves away or closes, leaving workers jobless.

Social forces also contribute to poverty. For example, certain employers purposely try to avoid hiring blacks and other members of minority groups. Other employers pay such people less than similarly qualified workers who are not members of minority groups. Laws prohibit such unequal treatment in the United States, but it persists and adds to neediness among minorities.

Many women become poor after they have become widowed, divorced, or separated from their husbands. Some of them lack the education, job experience, and skills they need to support themselves and their children. Many women also have difficulty obtaining the child-care services they need to work outside the home. In addition, many employers pay women less than similarly qualified men, though such policies are illegal.

The fight against poverty

Many Americans believe the United States has enough resources to eliminate poverty. However, Americans disagree about the best way to accomplish this task. The federal government—along with the state governments—fights poverty with three major weapons: (1) measures to improve job opportunities, (2) educational programs, and (3) social welfare programs.

© Owen Franken, Stock, Boston

Victims of poverty often suffer from poor nutrition, inadequate medical care, and emotional anxiety. As a result, many of them cannot become productive workers or active citizens.

Measures to improve job opportunities include efforts to reduce unemployment. For example, the government tries to promote economic growth and stability, which keep the demand for workers high. Under the federal Job Training Partnership Act, state and local governments receive federal funds to provide job training for unskilled, disadvantaged youths and for needy adults. The Job Corps furnishes job training for unemployed people between the ages of 16 and 22. The Equal Employment Opportunity Commission seeks to promote equal job opportunities for women and minority group members.

State and federal minimum-wage laws establish the lowest hourly wage employers can pay. But some people argue that minimum-wage laws contribute to unemployment. They say some companies cannot afford to pay workers the minimum wage. Laws that force these firms to raise their wages may force them to close or to employ fewer workers, increasing unemployment.

Educational programs are designed to give the poor the knowledge and skills they need to support themselves. Such programs serve people of all ages. The Head Start program offers educational, medical, and social benefits to preschool children from low-income families. School integration and bilingual education attempt to improve the education of members of minority groups. Scholarships, loans, and work-study programs help many needy students attend college. Adult Basic Education trains adults in such skills as reading and arithmetic. Educational programs, such as programs that improve job opportunities, receive wide support. However, they cannot help all the poor.

Social welfare programs provide money, food, medical care, and other aid to the poor and certain other groups. The government provides two main types of aid: *social insurance* and *public assistance*. Social insurance mainly covers people—or their families—who have worked and paid special taxes in the past, whether or not they are poor. Public assistance provides aid to the needy regardless of their work record.

Social-insurance programs include (1) Social Security, (2) unemployment insurance, and (3) workers' compensation. Social Security pays benefits to retired or disabled workers and their dependents. It also provides financial aid to the families of workers who have died. Social Security includes a health insurance program called *Medicare*. Medicare helps the aged and the disabled pay medical costs. Unemployment insurance pays workers who have lost jobs. Workers' compensation gives cash and medical care to workers who have been hurt on the job and cannot work as they could before.

Public-assistance programs, also called welfare programs, include (1) cash aid for the poor, (2) food stamps and other nutrition programs, (3) Medicaid, (4) Supplemental Security Income, (5) housing programs, and (6) day-care programs. Cash aid programs provide money to poor people who cannot support themselves or their dependents. Food stamps, which are available to low-income families, can be exchanged for certain kinds of groceries. Medicaid pays medical expenses for many people who otherwise cannot afford them. Supplemental Security Income guarantees a minimum income to the aged and to the blind and others who are disabled. Housing programs include the construction of public housing for the poor and financial aid, which is used to help needy people pay their rent. Day-care services for children enable low-income parents to hold jobs or to get training outside the home. Sheldon H. Danziger

Powder. See Cosmetics; Gunpowder.

Powder horn was a container for carrying the gunpowder used in muzzleloading firearms. People usually used cattle horns for powder horns. The hollow horn was cut at both ends and then scraped on the inside. Caps constructed of metal or wood were attached to the ends to hold the powder in. To load a gun, the cap on the small end of the horn was removed, and the powder was poured into a measure for the correct charge. People often decorated powder horns, and they usually wore the horns slung over the shoulder.

Douglas M. Wicklund

Powder metallurgy is a process that reduces metals to powdered form and presses the powder into certain somewhat restricted shapes. A heating process called *sintering* is used to bind the metal powders and add strength to the finished product.

Powder metallurgy has many advantages over other methods of making metal objects. Some metals will not mix (alloy) when heated to the *fusion* (melting) point. But these metals can be made to form valuable compounds by powdering them and then mixing the powders together. For example, graphite will not fuse with metals by heat alone. But it can be powdered and mixed with powdered metals, pressed into shape, and heated to make a bearing. Such a bearing does not need frequent oiling because the graphite acts as a self-lubricant. Other advantages of powder metallurgy include rapid production, high dimensional accuracy, controlled *porosity* (number, shape, and size of pores), low scrap loss, and use of unskilled labor.

Metals are made into powders in many ways. Molten metals can be *atomized* (broken down into tiny drops), and some solid metals can be crushed. Another method is electrolysis (see **Electrolysis**). A fourth way is to heat the oxide compound of the metal in contact with hydrogen. Joel S. Hirschhorn

Powell, Adam Clayton, Jr. (1908-1972), was a political and religious leader of New York City's Harlem area. From 1945 to 1955, he and William Dawson of Chicago were the only African Americans in the United States Congress. Powell condemned all forms of segregation and discrimination, especially in his early years in Congress. Later, his absenteeism, boastful attitude, and colorful private life disappointed many reformers and offended many members of Congress. But he remained popular in his congressional district.

Powell became pastor of the Abyssinian Baptist

Church in Harlem in 1937. He was first elected to the U.S. House of Representatives in 1944. In 1960, he became chairman of the House Committee on Education and Labor. Powell was denied his seat in Congress by the House in 1967 on grounds he misused public funds. He won a special election to fill the vacancy, but he did not claim his seat. He won the regular election in 1968 and returned to Congress in January 1969. In 1969, the Supreme Court of the United States ruled that Congress had acted unconstitutionally when it excluded Powell in 1967. In 1970, he was defeated in his bid for renomination in the Democratic primary.

Wide World
Adam Clayton Powell, Jr.

Powell was born on Nov. 29, 1908, in New Haven, Connecticut. He graduated from Colgate University and received graduate degrees from Columbia and Shaw universities. Richard Bardolph

Powell, *POH uhl,* **Anthony** (1905-2000), an English writer, became best known for his 12-volume series of novels called *A Dance to the Music of Time.* In the series, Powell described what he considered the changing nature of the English upper-middle class from the early 1920's to the 1970's. The novels are narrated by Nicholas Jenkins, who speaks for Powell. Jenkins records his experiences and those of a group of characters, especially Widmerpool, a ruthless, aggressive, self-made man. The series began with *A Question of Upbringing* (1951) and concluded with *Hearing Secret Harmonies* (1975).

Powell was born on Dec. 21, 1905, in London. He began his literary career with the comic satiric novels *Afternoon Men* (1931), *Venusberg* (1932), *From a View to a Death* (1933), and *Agents and Patients* (1936). Powell also wrote *John Aubrey and His Friends* (1948), a biography of English author John Aubrey. His plays include *The Garden God* (1971) and *The Rest I'll Whistle* (1971). Powell wrote four volumes of autobiography (1976-1982) under the title *To Keep the Ball Rolling.* Garrett Stewart

Powell, Colin Luther (1937-), became the first African American secretary of state of the United States in 2001. President George W. Bush appointed Powell, a former U.S. Army general, to the post.

Powell was born on April 5, 1937, in New York City. His parents were Jamaican immigrants. He graduated from the City College of New York and earned an M.B.A. degree from George Washington University. He was commissioned a second lieutenant in the Army in 1958. He served in Vietnam in 1968 and 1969. He later headed forces in South Korea, West Germany, and the United States. In 1986, he became commanding general of the Fifth Corps in Germany. In 1987, President Ronald Reagan named him assistant to the president for national security affairs. In 1989, President George H. W. Bush appointed Powell chairman of the Joint Chiefs of Staff, the nation's highest military advisory group.

Reuters/Archive Photos
Colin Luther Powell

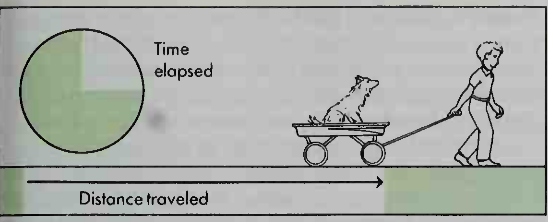
In 1991, Powell won the Spingarn Medal for his achievements. In 1993, he retired as Joint Chiefs of Staff chairman and from the Army. He wrote *My American Journey* (1995), an autobiography. In 1997, President Bill Clinton appointed him chairman of a campaign directed toward helping children develop learning and work skills. Joel D. Meyerson

Powell, John Wesley (1834-1902), was an American explorer, geologist, and biologist. He is known as an explorer of the Colorado River, an expert on the arid lands of the West, and an early environmentalist.

Powell was born on March 24, 1834, in Mount Morris, New York. He attended several colleges but never earned a degree and was largely self-taught. Powell served in the Union Army during the American Civil War (1861-1865). He lost his lower right arm in the Battle of Shiloh in 1862. From 1865 to 1867, he was a professor of natural science at Illinois Wesleyan University.

In 1868, Powell explored the Green and Colorado rivers in what are now Colorado and Utah. A year later, he led the first expedition of white men to travel in boats down the Colorado through the Grand Canyon in what is now Arizona. During his journeys, Powell recorded his observations of the terrain and the plant and animal life. He also studied the cultures of the Indian tribes he encountered along the way.

In 1879, Powell became director of the Bureau of Ethnology, devoted to studying American Indians. He held the office until his death on Sept. 23, 1902. From 1881 to 1894, he had also served as director of the United States Geological Survey. Helen Delpar



Powell, Lewis Franklin, Jr. (1907-1998), was an associate justice of the Supreme Court of the United States from 1972 to 1987. President Richard M. Nixon nominated him to fill the vacancy created when Justice Hugo L. Black retired.

Powell was born on Sept. 19, 1907, in Suffolk, Virginia. He attended Washington and Lee University and graduated from the university's law school in 1931. He earned a master's degree from the Harvard Law School the next year. From 1932 to 1972, Powell practiced law in Richmond, Virginia, and was regarded as one of the state's most distinguished lawyers. Powell served as president of the American Bar Association in 1964 and 1965. In that position, he proposed various improvements in court procedures and in legal aid to the poor.

On the Supreme Court, Powell generally held conservative views, especially in cases involving criminal justice. For example, he supported state laws imposing the death penalty. However, he often provided the decisive "swing vote" in the court's 5-4 decisions. In 1986, he cast the deciding vote in two major court rulings viewed as victories for liberals. One of these decisions supported affirmative-action programs, and the other reaffirmed the court's 1973 ruling establishing a woman's right to have an abortion. Owen M. Fiss

Power, in physics, is the rate of doing work. Physicists consider that work is done whenever a force moves an

WORLD BOOK diagrams by Leon Bishop

The power needed to pull a wagon depends on its weight, and how far and how fast it is pulled. A boy uses a certain amount of power to pull a dog in a wagon over a given distance in a set time, *above.* He must use twice as much power to pull the dog and wagon over the distance in half the time, *below.*

object against a resistance. The amount of work done depends on the size of the force and on the distance that the object moves in the direction of the force. The idea of power involves time, as well as force and distance. The power exerted determines the amount of work that can be accomplished per unit of time.

A task requires the same amount of work whether done quickly or slowly. But greater power is necessary to do the work quickly. For example, a horse does the same amount of work if it pulls a load over a given distance in 20 seconds or in 10 seconds. But it must use twice as much power to perform the task in the shorter time.

Power can be calculated with the following formula:

$$P = \frac{W}{t}$$

In the formula, P stands for power, W for work, and t for time. Physicists measure work by multiplying the force times the distance. Therefore, the formula for power can also be written:

$$P = \frac{Fd}{t}$$

Here F stands for force and d for distance.

In systems of measurement, power is always expressed as units of work divided by units of time. The basic unit of power in the customary, or English, system is *foot-pounds per second.* One foot-pound of work is done when a force of 1 pound moves an object 1 foot. For example, if a 100-pound object is lifted 2 feet, the work done equals 200 foot-pounds. If the work is performed in 4 seconds, the power used is 50 foot-pounds per second:

$$P = \frac{100 \text{ pounds} \times 2 \text{ feet}}{4 \text{ seconds}} = \frac{50 \text{ foot-pounds}}{1 \text{ second}}$$

Another unit of power in the customary system, the *horsepower,* equals 550 foot-pounds of work per second. The horsepower originally represented the amount of power delivered by a typical draft horse.

In the metric system, the common unit of power is the *watt.* A watt is the power needed to perform one *joule* of work per second. A joule of work is done when 1 *newton* of force moves an object 1 meter (see Newton). One horsepower equals 746 watts.

Force		

Power, in the social sciences, is the ability of persons or groups to impose their will on others. Persons with power can enforce their decisions by applying, or threatening to apply, penalties against those who disobey their orders or demands. Power is present in almost all human relationships. Teachers have power over students, employers over employees, parents over children, bullies over weaklings, and militarily strong nations over weak nations.

Forms of power include *coercion, influence,* and *authority.* Coercion is the use of physical force to enforce decisions. Influence is the ability to produce an effect through example, persuasion, or some other means without using force.

Authority is power that is based on agreement by a majority of the members of a society or group. For example, teachers have power (authority) over their students because it is widely recognized and agreed that they must have it to keep order and teach effectively. In democracies, the authority of government is based on the consent of the governed. Leaders chosen by the voters in free elections have authority to make decisions for the people.

Main sources of power include (1) superior resources, (2) superior numbers, and (3) superior organization.

Resources may be physical or human. Physical resources include money, goods, and property. They give a person the power to buy what he wants, and enable him to command the services of others. Human resources that give power include intelligence, knowledge, skill, prestige, social position, bravery, and personal charm or beauty. Such qualities become a source of power when they enable a person to lead, influence, or control other persons.

Power in numbers can be seen in elections which give the winners the authority to make decisions for the group. But numbers are not all-important. Inferior numbers can exercise power when they have control of important resources, such as the military.

Superior numbers and resources do not by themselves give a person a high degree of power over others. People must know how to use their resources effectively. They do this through organization. Individuals alone have relatively little power to affect important decisions. But by joining together in some kind of organization, they can become powerful. Political parties, pressure groups, and other associations attempt to gain power through social organization. Countries also join together to consolidate power. International power groups include the European Economic Community (EEC) and the Organization of American States (OAS).

Systems of power. Power relationships occur in all societies and organized groups. There are important differences in how private and public power systems en-

force their decisions. The leaders of private groups—such as businesses and clubs—can fine, suspend, and even expel dissenting members. But only public power systems—that is, governments—can legally use physical force, including imprisonment. Governments control the police and the military, the chief agents of force. This monopoly of force makes control of the state an important source of power.

The social organization that enables certain people to govern in all the organized groups of a community or society makes up the *power structure.* Sometimes, the most powerful people are referred to as *the Establishment,* or the *power elite.* Wolf Heydebrand

See also **Government.**

Power, in arithmetic, is the product of a number multiplied by itself a specified number of times. For example, $3 \times 3 \times 3 \times 3 \times 3$ is called the fifth power of 3 and is written 3^5. In 3^5, the number 3 is called the *base* and 5 is called the *exponent.* The second and third powers of a number are called its *square* and its *cube* (see **Cube; Square**). The first power of a number is the number itself, and the zero power of a number is one. For example, 3^1 is 3 and 3^0 is 1. The concept of power also applies to negative numbers and fractions. For example,

$$3^{-2} \text{ is } \frac{1}{3^2} \text{ and } 3^{\frac{1}{3}} \text{ is } \sqrt[3]{3}.$$

Power of attorney is a legal, written document. The signer of the document appoints an agent or attorney who has the power to act for the signer. The appointed person can act as if he or she were the actual signer rather than merely the agent of the signer (see **Agent**). When a power of attorney is officially recorded, it must generally be certified by a notary public.

The power of attorney is especially useful to people who are ill and unable to conduct their own affairs, or to people who must be away from home for a long time. In times of war, many members of the armed forces make out a power of attorney to someone at home. This is especially true of those who leave civilian business to the management of friends and relatives.

A *general* power of attorney permits the agent to act for the signer in all circumstances. A *special* power of attorney permits the agent to do only those things that the signer lists in the document. The death of the signer voids the power of attorney. Sherman L. Cohn

Power plant is any system that generates power. Power plants include the various engines used in airplanes, automobiles, locomotives, and other vehicles. Most of these power plants use gasoline or oil for fuel. Larger power plants, often called *power stations,* use coal, nuclear fuel, or oil to produce electricity.

Related articles in *World Book* include:

Airplane (Power for flight)	Gasoline engine	Rocket
Automobile (The engine)	Horsepower	Solar energy
Diesel engine	Hydraulic engine	Steam engine
Electric power	Jet propulsion	Turbine
	Locomotive	Water power
	Nuclear energy

Powers, Hiram (1805-1873), was one of the best-known American sculptors of the mid-1800's. His *Greek Slave* (1843), a full-length female nude, ranks among the most famous sculptures in American art. Praised as a symbol of beauty, virtue, and innocence, the marble statue helped establish the nude as an acceptable subject for art in the United States.

Powers was especially gifted at creating realistic portrait busts of famous people, including *Andrew Jackson* (1835) and *Henry Wadsworth Longfellow* (1869). His other works include *Fisher Boy* (1844), *California* (1850), *Benjamin Franklin* (1862), and *Thomas Jefferson* (1863). He was born in Woodstock, Vt. George Gurney

Powhatan, *pow uh TAN* or *pow HAT uhn* (?-1618), was the Indian chief in the romantic story about John Smith and Pocahontas. Smith was a soldier who had helped establish the first permanent English colony of North America, at Jamestown in what is now Virginia. Powhatan was ready to kill Smith when Pocahontas, the Indian's favorite daughter, stopped him and saved Smith's life. No one knows if this story is true. Powhatan is also famous for building the Powhatan Confederacy of Virginia (see **Powhatan Indians**).

Powhatan at first sought to use the colonists as allies against native enemies and as sources of weapons and trade goods. But the colonists' rude behavior and demands angered him. Powhatan attacked the colony repeatedly until 1614, when Pocahontas was kidnapped by the English and married John Rolfe, a settler.

Powhatan's real name was *Wahunsonacock.* But he was called Powhatan after his favorite village, which was near present-day Richmond, Va. James Axtell

See also **Pocahontas; Smith, John.**

Powhatan Indians, *pow uh TAN* or *pow HAT uhn,* formed a small but powerful tribe of eastern North America. They controlled the Powhatan Confederacy of Virginia, which once included as many as 30 tribes totaling about 9,000 people. The confederacy occupied much of what is now Virginia. The chief of the Powhatan tribe headed the confederacy. A famous chief, Wahunsonacock, was also known as Powhatan (see **Powhatan**). Jamestown, first permanent English settlement in North America, was made among the Powhatan.

The customs of the Powhatan resembled those of other eastern coast tribes. The Powhatan worshiped animal spirits, especially the Great Hare (creator).

In the early 1600's, the Powhatan often clashed with the settlers, particularly under Opechancanough (see **Indian wars** [Colonial days]). Later, the tribe seemed to no longer exist. During the mid-1900's, however, a revived confederacy was formed by several hundred Indians in Virginia and Delaware who claimed to be Powhatan.
Donald L. Fixico

Poznań, *PAWZ nahn yuh* (pop. 589,700), is a city that lies on the Warta River in west-central Poland (see **Poland** [political map]). Products of Poznań include machinery, metals, and transportation equipment. The city has two universities and many historic buildings. It was probably founded about A.D. 800. In 1956, antigovernment riots in Poznań and other Polish cities resulted in reforms that gave the people more economic, educational, and religious freedom. Janusz Bugajski

Prado. See **Madrid** (Education and cultural life).

Praetor, *PREE tuhr,* was the chief legal officer of ancient Rome. Citizens brought complaints before the praetor. The praetor decided which complaints were justified and assigned them to judges for trial. When taking office, a praetor issued an *edict* (public order) stating how the law would be interpreted in granting trials. Each new praetor generally copied or improved upon the successful edicts of earlier praetors. In that way, praetors helped to build the Roman legal system, which in turn influenced many of the legal systems used today. Praetors also served as governors of Roman provinces, and later they presided over criminal courts.

The office of praetor was created in 367 B.C. The number of praetors was increased to two in 242 B.C., and eventually increased to 16. D. Brendan Nagle

See also **Law** (Ancient Roman law).

Praetorian Guard, *pree TAWR ee uhn,* was the personal guard of the Roman emperors. Until the reign of Septimius Severus (A.D. 193-211), only soldiers recruited in Italy could serve in the guard. Septimius opened the guard to soldiers from all the Roman legions.

Emperor Augustus made the praetorians a standing army. He divided them into nine *cohorts* (groups) of a thousand soldiers each. Three cohorts remained in Rome, and the others were stationed in nearby cities. Members of the guard received much higher pay than other soldiers. The praetorians eventually became so powerful they could overthrow emperors whenever they chose. Emperor Constantine finally abolished the guard in A.D. 312. Arther Ferrill

See also **Rome, Ancient** (picture: The praetorians).

Pragmatic sanction, *prag MAT ihk SANGK shuhn,* was a type of decree concerning church or state matters issued by European rulers. The most important pragmatic sanction was privately issued by the Habsburg Emperor Charles VI in 1713 and publicly announced in 1724. At that time, German law required rulers to pass their property on to their oldest male heirs. Charles was a member of the Habsburg family. His pragmatic sanction declared that his family's holdings could be inherited by his oldest daughter if he had no sons. It also stated that the Habsburg lands could not be divided.

Several countries recognized the decree. But Charles died without a male heir in 1740, and most of these countries soon broke their pledges. Their refusal to recognize the claim of Maria Theresa, Charles's oldest daughter, to all of her father's territories led to the War of the Austrian Succession. Charles W. Ingrao

See also **Maria Theresa; Succession wars** (The War of the Austrian Succession).

Pragmatism, *PRAG muh tihz uhm,* is a philosophy that attempts to apply the methods of science to philosophy. Its central idea is that the meaning and truth of an idea are determined by the idea's effects in practice and on conduct. Three American philosophers—Charles Sanders Peirce, William James, and John Dewey—developed pragmatism. Peirce originated the philosophy, James made it popular, and Dewey extended it to key areas of life. Each of these men interpreted pragmatism in his own way.

Peirce first presented the basic ideas of pragmatism in a series of essays called "Illustrations of the Logic of Science" (1877-1878). Peirce conceived of belief as something on which we are prepared to act, not just as a state of mind. He defined belief as a *habit* or *rule of action.* He called doubt (the opposite of belief) an unsatisfactory state from which we struggle to free ourselves. For Peirce, thinking, or *inquiry,* was the struggle to eliminate the irritation of doubt. Peirce thus regarded inquiry as a practical activity—not just something that goes on in our heads. Inquiry aims to eliminate doubt by arriving at a settled belief.

Peirce's writings were technical and attracted little attention when they were published. Pragmatism as a philosophical movement began in 1898, when William James restated Peirce's ideas in more popular language. According to James's interpretation of Peirce, the concrete meaning of any abstract or general proposition can be traced to a particular concrete consequence in our future practical experience. Therefore, supposedly different ideas that have identical consequences in practice are really the same idea expressed in different words.

James's interpretation of pragmatism stated that the meaning of an abstract idea is determined by the idea's effects on one who believes it. James wrote that a true idea is one that can be verified, that "works," and that satisfies. According to this concept, truth is changeable. Because a true idea is one that agrees with reality, James concluded that we can make ideas true by our actions and change the world in which we live.

John Dewey was greatly influenced by the English biologist Charles Darwin and Darwin's theory of evolution. Dewey conceived of thought and of the mind as instruments developed in the course of evolution to allow human beings to reshape their environment. Dewey's version of pragmatism, later called *instrumentalism,* stated that all ideas are instruments. Therefore, true ideas are those that work best for attaining human goals. Dewey urged that philosophy become a tool for dealing with the specific problems of all human beings rather than with the remote problems of philosophers. Dewey advocated that the method of science be used to reshape education, morals, politics, and society.

Pragmatism became the most important philosophical movement in the United States during the early 1900's, and it has had an enormous influence on American life. Pragmatism has been called a typically American philosophy because of its basic optimism, its emphasis on action, and its belief in a future that can be changed by human ideas and efforts. Many people claim that pragmatism expresses the essential American character.

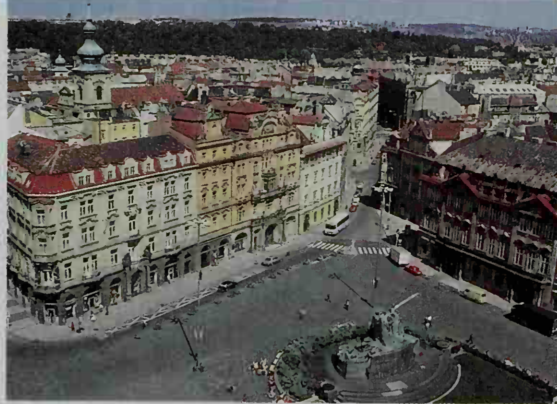
Prague, *prahg* (pop. 1,215,656), is the capital and largest city of the Czech Republic and an important center of culture and learning. Prague, called Praha in the Czech language, is one of the oldest and most beautiful cities in central Europe. It lies on the Vltava River, in the central part of the country (see **Czech Republic** [map]).

Prague is called the "City of a Hundred Spires" because of its many churches. It was one of the few central European cities that escaped major damage during World War II (1939-1945).



The city lies on both banks of the Vltava River. A number of bridges connect the two sections of Prague. The Charles Bridge, a stone structure lined with statues of saints, is the most famous one. The city covers about 70 square miles (180 square kilometers). Much of the city's area is made up of scenic hills.

Prague Castle, once the home of the kings of Bohemia, stands on *Hradčany* (Castle Hill) on the left bank of the Vltava River. Prague Castle houses a number of art treasures, and part of the castle serves as the official residence of the president of the Czech Republic. St. Vitus' Cathedral also stands on Hradčany. Many beautiful old palaces and other structures line the narrow, winding streets of Malá Strana, a district of Prague that is located on the slopes and at the bottom of the hill.

Old Town, the historic center of Prague, lies on the right bank of the Vltava, across from Hradčany. Old Town Hall and the Týn Church are in Old Town Square. Old Town Hall, built during the 1300's, served as the seat of the city government for hundreds of years. It has a famous clock with statues of the 12 apostles that move every hour. A monument to John Hus, a religious reformer of the early 1400's, stands in the middle of the square. The Týn Church was the main church of the Hussite reformers (see **Hus, John**). Many buildings of Charles University, founded in 1348 by King Charles IV of Bohemia, are in Old Town.

The business center of Prague is in New Town, also located on the right bank of the river. Much of the New Town area was built during the 1800's. Its Wenceslas Square—which is actually a wide boulevard lined with hotels, restaurants, and shops—is the busiest street in Prague. The National Museum occupies one end of Wenceslas Square. A statue of Saint Wenceslas stands in front of the museum. Prague also has many other museums, as well as libraries, theaters, opera houses, and concert halls.

Residential neighborhoods lie north, south, and west of Prague. Factories have been built chiefly in the eastern and southern suburbs.

Jessie Blackburn, FPG

Prague's Old Town Square is lined with historic buildings. A memorial to religious reformer John Hus is in the foreground.

People. Most of Prague's people are Czechs. The city had a large German community before World War II, but most of the Germans were expelled after the war. Because of government restrictions on migration to Prague and a low birth rate, the size of the population has increased only slightly since the war ended.

Prague has a housing shortage. Many houses in the city were built during the early 1900's and are in poor condition. Since the mid-1900's, the government has constructed many apartment buildings in the suburbs. But many people still live in crowded city apartments.

Economy. Prague ranks as one of the country's leading manufacturing centers. The city's most important industrial products include aircraft engines, automobiles, beer, chemicals, diesel engines, furniture, machine tools, optical instruments, processed food, and streetcars. Prague also is an important railroad center.

History. Prague was probably founded during the A.D. 800's. It soon grew into an important trading center. In time, the city became the residence of the Bohemian kings, who were crowned in St. Vitus' Cathedral. King Charles IV, who also ruled the Holy Roman Empire, erected many important buildings. He founded the first university in central Europe in Prague in 1348. The Hussite religious reformation began in Prague during the 1400's, and Prague suffered much damage in the religious wars that followed.

The Thirty Years' War began in Prague in 1618 after Protestant Bohemians rebelled against the Roman Catholic Habsburg (or Hapsburg) emperor. The revolt failed, and the Habsburgs ruled Prague until the end of World War I in 1918. That year, the city became the capital of the new nation of Czechoslovakia.

German troops occupied Prague during World War II. Many of Czechoslovakia's people, including thousands of Jews, were killed by the Germans. In 1945, at the end of the war, the Soviet Army entered Prague. The Czechoslovak Communist Party, supported by the Soviets, took control of Czechoslovakia in 1948.

For a brief period in 1968, Prague was the center of a liberal reform movement, sometimes called the *Prague Spring,* in Czechoslovakia. The movement ended after tanks and soldiers from the Soviet Union and several other Eastern European Communist countries swept into Prague. In the late 1980's, Prague was also the center of the movement that led to the end of Communist control of Czechoslovakia. In 1993, the independent countries of the Czech Republic and Slovakia were formed to replace Czechoslovakia. Prague remained the capital of the Czech Republic. Vojtech Mastny

Prairie is a region of flat or hilly land covered chiefly by tall grasses. The pioneers who first saw the flat prairies of the American Middle West described them as a "sea of grass." The wind blew gentle waves in a green carpet of grasses. In some places, the grasses grew taller than an adult. Today, corn and wheat fields cover most of the prairie. Few prairies remain untouched.

The North American prairie extends from central Texas to southern Saskatchewan. It includes most of Oklahoma, Kansas, Nebraska, Iowa, Illinois, South Dakota, and North Dakota, and parts of other nearby states and provinces. Alberta, Saskatchewan, and Manitoba are called the "Prairie Provinces" of Canada. Other prairies include the Pampa of Argentina, the *veld* of

Prairies are covered chiefly by tall grasses. Few natural prairie regions remain in the world because most of them have been turned into farms or grazing land. The prairie shown at the left lies in Waterton Lakes National Park in Alberta, Canada.

Artstreet

South Africa, the Canterbury Plains of New Zealand, and parts of Hungary, Romania, Russia, and Ukraine.

Climate and soil. Prairies have hot summers, cold winters, and moderate rainfall. Summer temperatures may reach well over 100 °F (38 °C) and winter temperatures may drop as low as −40 °F (−40 °C). Tropical grasslands, where temperatures vary less from summer to winter, are called *savannas* (see **Savanna**). Most prairies receive from 20 to 35 inches (51 to 89 centimeters) of rain a year—less than forests get but more than *steppes* (regions of short grasses) receive. Most of the rain falls in late spring and early summer.

Prairie soils have especially deep, dark, fertile upper layers. Such soils result from the growth and decay of deep, many-branched grass roots. The rotted roots hold the soil together and also provide a source of food for living plants. The richest, blackest prairie soils are called *chernozems.* This term comes from a Russian word meaning *black earth.*

Life on the prairie. The thick cover of grasses of the American prairie consists of many species. Each kind of grass grows best in a certain kind of environment but also occurs in other places. For example, slough grass is found in low, marshy ground. Big bluestem, Indian grass, switch grass, and wild rye thrive in fairly moist areas. Drier areas have little bluestem, dropseeds, June grass, blue grama, needlegrasses, and side oats grama. In the moist eastern parts of the prairie, near forested areas, the grasses may grow 6 feet (1.8 meters) high or even taller. On the dry western edge, the grasses grow only about 2 feet (61 centimeters) high. There, the prairie gradually changes to a steppe.

Many kinds of nonwoody plants other than grasses also grow on the prairie. Hundreds of species of flowers add splashes of yellow, orange, red, purple, and other colors to the sea of grass. Many of these wildflowers belong to the *composite* family or to the *legume* family of plants. Composites that grow on the prairie include such flowers as asters, blazing stars, coneflowers, goldenrods, and sunflowers. Prairie legumes include clovers, psoraleas, and wild indigos. A purplish phlox and an orange-flowered milkweed called butterfly weed also color the prairie.

Cattails and sedges rustle in the breeze in marshy areas and near lakes and ponds on the northern prairie. Some woody shrubs, such as the prairie rose, grow among the grasses. A few trees, including cottonwoods, oaks, and willows, grow in river valleys on the prairie.

Many animals feed on the leaves, roots, and seeds of prairie plants. Some of these animals, such as jack rabbits, deer, and pronghorns, use their speed to escape from enemies. Others, including mice and prairie dogs, hide in underground burrows. Such birds as blackbirds, grouse, meadowlarks, quail, and sparrows build their nests in a thick cover of plants. Until the late 1800's, large herds of bison—commonly called buffaloes—roamed the American prairie.

Coyotes, foxes, and skunks feed both on smaller prairie animals and on certain plants. Badgers, hawks, owls, and some species of snakes eat meat almost entirely. Insects—especially grasshoppers and leafhoppers—and spiders are also common on the prairie.

The soil of the prairie contains millions of tiny organisms that feed on dead plants and animals. These organisms include bacteria and fungi as well as such soil animals as centipedes, earthworms, mites, and nematodes. All of them speed the process of decay among the dead plants and animals. This decaying process provides the soil with food for future generations of prairie plants.

René W. Barendregt

Prairies

The world's largest prairie lies in North America. This map also shows other large prairie regions of the world.

Prairie-chicken is the name of two species of North American grouse. These birds live in the central and western plains of the United States. The *greater prairie-*

Dave Spier, Tom Stack & Assoc.

Prairie dogs keep a sharp lookout for their enemies. The black-tailed prairie dogs pictured here have gathered at an entrance to one of their burrows. Prairie dogs live in large groups called *colonies* or *towns.*

chicken is about 18 inches (46 centimeters) long and weighs about 2 pounds (0.9 kilogram). Its feathers are yellowish-brown and white above, crossed with black bars, and white and brown barred below. Its head is deep buff with brown stripes. The *lesser prairie-chicken* is somewhat smaller, measuring about 16 inches (41 centimeters) long. Its feathers are paler than those of the greater prairie-chicken.

Prairie-chickens have unusual courtship habits. The male bird erects the feather tufts on his neck, spreads and raises his tail, and stretches out his wings and allows them to droop. He inflates two pouches on the side of his throat and makes a hollow booming noise. The male also leaps and dances during the courtship period.

The number of prairie-chickens has decreased greatly since the mid-1800's, chiefly because their habitats have been turned into farmland. The lesser prairie-chicken inhabits the southern Central Plains, from Kansas to Texas. The Greater prairie-chicken now lives in isolated areas from Michigan and Illinois westward to the Great Plains. They once lived as far east as Massachusetts. The heath hen, a subspecies of the greater prairie-chicken, has been extinct since the 1930's. Bertin W. Anderson

Scientific classification. Prairie-chickens belong to the family Phasianidae. The greater prairie-chicken is *Tympanuchus cupido;* the lesser prairie-chicken is *T. pallidicinctus.*

See also **Bird** (picture: Birds of grasslands); **Grouse.**

Prairie dog is a burrowing rodent that lives in western North America. It belongs to the squirrel family. The animal gets its name from the *prairies* (grassy plains) where it lives, and from its warning call, which sounds like a domestic dog's bark.

Prairie dogs have short legs; long, sharp claws; small eyes at the top of the head; and a short tail. Their thick fur is light brown. Adults measure from 9 to 15 inches (23 to 38 centimeters) in length, including the tail, and weigh from 1 to 3 pounds (0.5 to 1.4 kilograms).

There are five *species* (kinds) of prairie dogs. The *Black-tailed prairie dog,* the most common kind, inhabits the Great Plains from southern Canada to northern Mexico.

Habits. Prairie dogs live in burrows. They come out of their burrows only in the daytime to eat. Their diet consists mostly of plants, especially grasses. Occasionally they eat grasshoppers and other insects.

Prairie dogs are social animals. They live in large groups called *colonies* or *towns* that may contain more than 500 residents. Each colony of black-tailed prairie dogs contains many family groups called *coteries.* A typical coterie consists of one adult male, three or four adult females, and several offspring. Coterie members defend their territory by fighting or chasing off trespassing prairie dogs from other groups. A territory usually has 25 to 50 burrows, some as deep as 16 feet (5 meters). Most burrows have at least two entrances surrounded by mounds. The mounds protect burrows from flooding, improve underground ventilation, and provide prairie dogs with perches to watch for predators.

The enemies of prairie dogs include American badgers, bobcats, coyotes, red-tailed hawks, golden eagles, and prairie falcons. When a prairie dog sees a predator, it commonly gives a loud alarm. Other prairie dogs then run to their burrow mounds to watch the predator. They only submerge underground if the predator approaches within 10 to 15 feet (3 to 4.6 meters).

Black-tailed prairie dogs mate in the winter. The female carries her young for about 34 days and then gives birth to one to six blind, hairless babies. The young stay underground for about 6 weeks before they emerge from their burrows. Males leave the original coterie when they are about 12 months old, and each attempts

Brian Parker, Tom Stack & Assoc.

The black-tailed prairie dog has a tail tipped with black fur. This prairie dog lives in an area of the Great Plains from southern Canada to northern Mexico.

to take over a coterie from an older male. Most females remain in the original coterie for life. About half of all prairie dogs die before they are 1 year old. Males that survive the first year sometimes live five years, and females eight.

Prairie dogs and people. Over time, ranchers and other people have reduced prairie dog populations by killing them and destroying their habitats. All five prairie dog species have now become threatened with extinction. Ranchers traditionally feared their livestock would step into prairie dog burrows and suffer leg injuries. They also believed prairie dogs ate grasses and other plants preferred by cattle. Yet horses and cows rarely step into burrows, and prairie dogs generally eat different plants than livestock eat. Moreover, prairie dog activities improve the quality of certain plants. For example, the animals expose subsoil when they dig, making the land more fertile. Thus livestock commonly prefer to feed within prairie dog colonies. More research is needed to better understand the relationship between prairie dogs and livestock. John L. Hoogland

Scientific classification. Prairie dogs belong to the squirrel family, Sciuridae. The black-tailed prairie dog is *Cynomys ludovicianus.* The other four species are *C. gunnisoni, C. leucurus, C. mexicanus,* and *C. parvidens.*

See also **Animal** (picture: Prairie dogs); **Gopher; Ground squirrel; Rodent; Squirrel.**

Prairie Provinces are the three Canadian provinces of Alberta, Saskatchewan, and Manitoba. These provinces make up a large region that borders Montana, North Dakota, and Minnesota. The Prairie Provinces cover a total of 758,100 square miles (1,963,470 square kilometers), or about a fifth of Canada.

The three provinces have more than three-fourths of Canada's farmland and provide much of the nation's cattle and grain. The region also has rich deposits of petroleum and many other minerals. Several cities in Alberta and Manitoba are important manufacturing centers.

About a sixth of Canada's people live in the Prairie Provinces. The 2001 Canadian census reported that the region had a population of 5,073,323, of whom about three-fourths lived in cities or towns. The population included about 180,000 people with American Indian ancestry, or about a third of the Indians in Canada. The largest cities of the region are, in order of size, Calgary, Alberta; Edmonton, Alberta; Winnipeg, Manitoba; Saskatoon, Saskatchewan; and Regina, Saskatchewan.

Economy. A majority of the income of the Prairie Provinces comes from industries that provide services rather than produce goods. However, agriculture and mining are more important to the region than they are to Canada as a whole.

Prairie farmers raise almost all of Canada's barley, wheat, and oats, and about three-fourths of the beef cattle. Cattle sales provide about a fourth of the region's farm income. Major farm products also include canola, corn, dairy goods, hogs, peas, potatoes, and poultry.

The Prairie Provinces produce about 90 percent of Canada's natural gas and petroleum, and the region has about half the known coal deposits in the nation. The majority of coal, gas, and oil produced in the region comes from Alberta. Southern Saskatchewan has the largest known potash deposits in the world. Thompson, Manitoba, ranks as one of the world's chief centers of nickel production. Other mined products of the Prairie Provinces include cobalt, copper, gold, quartz, salt, sand and gravel, sodium sulfate, uranium, and zinc.

The production of chemicals is the leading manufacturing activity in the Prairie Provinces. Other important manufactured goods include electrical equipment, fabricated metal products, machinery, printed materials, and processed foods and beverages.

Commercial fisheries operate on a number of lakes in the Prairie Provinces. Fur farmers and trappers of the region market valuable pelts. Airlines, highways, and railroads link the cities and towns of the Prairie Provinces. Ships carry cargo between Churchill, Manitoba, and Atlantic Ocean ports by way of Hudson Bay.

History. A number of American Indian tribes lived in what are now the Prairie Provinces when white explorers first arrived there. Major tribes included the Assiniboine, Blackfoot, Chipewyan, and Cree.

The English explorer Sir Thomas Button and his crew were probably the first white people to see the region. In 1612, they sailed down the west coast of Hudson Bay and claimed the land for England. In 1670, King Charles II of England granted control of most of what are now the Prairie Provinces to the Hudson's Bay Company of London, a fur-trading organization. The fur trade was the region's major economic activity for the next 200 years.

In 1869, the Hudson's Bay Company sold the region to the newly formed Dominion of Canada. Manitoba became a province in 1870, when the Dominion of Canada took possession of the region. In the late 1800's and early 1900's, millions of people settled in the region. They came from eastern Canada, the United States, and such European areas as Britain, Germany, the Netherlands, Poland, Scandinavia, and Ukraine. Alberta and Saskatchewan became provinces in 1905. Roderick C. Macleod

Praseodymium, *PRAY zee oh DIHM ee uhm* (chemical symbol, Pr), is one of the rare-earth elements. Its atomic number is 59, and its atomic weight is 140.90765. At 25 °C, its density is 6.475 grams per cubic centimeter (see **Density**). Austrian chemist C. F. Auer von Welsbach first discovered praseodymium in 1885, when he separated salts of the so-called element didymium into praseodymium and neodymium. The name *praseodymium* comes from the Greek words *prasios,* meaning *leek-green,* and *didymos,* meaning *twin.* The element received this name because it occurred in the green fraction, or part, of didymium. It is best separated from the other rare-earth elements by ion-exchange or solvent extraction processes.

Praseodymium melts at 931 °C and boils at 3520 °C. It makes a useful alloy, especially in *misch metal* (a mixture of rare earths). Praseodymium oxide is a black powder that dissolves in acid to form green solutions or green salts. These salts are used in the ceramics industry for coloring glass and for glazing. Larry C. Thompson

Pratt, E. J. (1882-1964), was a Canadian poet known for his epics of Canadian history and his narrative poems. The typical hero of his works is a group or community.

His first book, *Newfoundland Verse* (1923), marks his lifelong interest in the sea as a world of primitive clashes. *The Titanic* (1935) retells the story of the ocean liner that sank in 1912.

In *Brébeuf and His Brethren* (1940), Pratt wrote about Jesuit missionaries in Canada during the 1600's. *Towards the Last Spike* (1952) is an account of the construction of the Canadian Pacific Railway. Pratt's best works have been brought together in *The Collected Poems of E. J. Pratt* (1958). Edwin John Pratt was born on Feb. 4, 1882, in Western Bay, Newfoundland (now Newfoundland and Labrador), near Carbonear. Laurie R. Ricou

Praxiteles, *prak SIHT uh leez,* was one of the greatest Greek sculptors of the 300's B.C. He was one of the first sculptors to humanize the Greek gods and goddesses, a departure from the stern, remote, awe-inspiring figures of previous Greek sculptors.

National Museum of Athens (Raymond V. Schoder, S.J.)

Hermes is a Roman copy of a statue by Praxiteles. It shows the sculptor's lifelike style.

Praxiteles excelled in sculpting the beauty of the human form. Face and body features were delicately lifelike, and the marble surfaces had a lustrous finish. The eyes of his figures had a dreamy look. The hip was often thrust out, creating a graceful "S" curve, and giving the body a more relaxed appearance.

Although none of Praxiteles's work has survived, Greek and Roman copies of his sculptures exist that are excellent representations of his style. One famous copy is a statue of Hermes and the infant Dionysus (see **Hermes**). In antiquity, Praxiteles's most famous statue was the Aphrodite of Knidos. The statue was the earliest to show the goddess of love standing nude, modest but alluring. Praxiteles's Aphrodite was the inspiration for many later statues of the goddess. Praxiteles was born in Athens.

Marjorie S. Venit

Prayer refers to reverent words and thoughts directed toward God, gods, goddesses, or other objects of worship. People pray to ask for spiritual benefits for themselves or others. They also offer praise, thanks, or adoration to the object of worship. Prayers may take the form of speech, song, dance, or silent reverence. Some people kneel while praying. Others stand, sit, or lie down. Prayer is an important form of worship in nearly all the religions in the world. Most religions have regular prayers for both community and private worship. Individuals may also offer private prayers that express personal thoughts. *Contemplation* is prayer in which a person concentrates only on the object of worship.

Predestination is the belief that God foresees and wills from all eternity that some individuals will be saved. Other terms for predestination include *election* and *foreordination*. The belief that God predestines some people for salvation and others for damnation is called *double predestination*. Both Christianity and Islam include a belief in predestination. This article deals with predestination in Christianity.

The doctrine of predestination has been a problem in Christian theology since the time of Saint Augustine, in the early 400's. The problem arises from the apparent conflict between the beliefs that God is all-powerful and that human beings have free wills. Some theologians have stressed the importance of human freedom, and others have emphasized God's power and grace in salvation. Augustine wrote that salvation is initiated only by God's freely given grace. In the 1500's, Martin Luther and other leaders of the Protestant Reformation taught that salvation depends entirely on God's all-powerful will. They believed that nothing humanity did could require God to grant salvation in return. The Protestant leader John Calvin taught the doctrine of double predestination.

Some people have criticized the doctrine of predestination as being negative and pessimistic. But Luther, Calvin, and others saw it as a doctrine that should free people from constantly worrying about and struggling to earn salvation. Because salvation is in God's hands, they believed, the individual should stop being anxious and simply trust in God. Albert J. Raboteau

Preeclampsia, *pree uh KLAMP see uh,* is a serious condition that affects about 5 percent of pregnant women. Preeclampsia can interfere with growth of the *fetus* (unborn baby) and lead to premature birth. It may result in the death of the mother, her unborn baby, or both. Symptoms usually occur late in pregnancy. They include high blood pressure, excessive protein in the urine, and body swelling. Preeclampsia was formerly called *toxemia of pregnancy*.

The cause of preeclampsia is unknown. Certain conditions, including overweight and diabetes, increase a woman's risk of developing preeclampsia. Good medical care during pregnancy detects most cases before they become severe. Preeclampsia can cause abnormal development or death of the fetus by restricting circulation of the mother's blood to the *placenta*. The placenta is the organ that transfers food and oxygen from the mother's blood to the fetus's blood.

Untreated preeclampsia may progress to *eclampsia*, an even more serious condition in which women suffer convulsions. Such symptoms as headache, abdominal pain, and extremely high blood pressure may appear before convulsions, or convulsions may occur without warning. Other dangers of eclampsia include

kidney failure, liver damage, and bleeding in the brain.

Doctors treat preeclampsia by prescribing bed rest and other measures that lower the patient's blood pressure. Some cases must be treated in a hospital. If warning signs of eclampsia develop, doctors give drugs to prevent convulsions. They also end the pregnancy early, by delivering the fetus surgically or using drugs to stimulate labor. After the pregnancy ends, the patient usually recovers rapidly. Marshall D. Lindheimer

Pre-emption is the act of buying something ahead of other persons, or the right to do so. The term comes from two Latin words, *emptio,* meaning *buying,* and *pre,* meaning *before.* Pre-emption had special meaning in the United States in the 1800's. People called *squatters* moved into unsettled areas and built on land they did not own. Real estate speculators called *claim-jumpers* often worked with lawyers to take the squatters' land.

Beginning about 1800, Congress granted the right of pre-emption to some squatters. In 1841, Congress passed a pre-emption law that applied to all squatters. Squatters who lived on surveyed government land and made improvements on it had the right to buy that land before anyone else could do so. When the land they occupied was offered for sale, they could buy up to 160 acres (65 hectares) of it for $1.25 an acre.

A person who already owned as much as 320 acres (129 hectares) of land could not get more by pre-emption. A married woman living with her husband could not get any land by pre-emption, and neither could a person who moved within the same state.

After the American Civil War (1861-1865), big land companies sent out "dummy" settlers, who filed applications for land which they did not intend to keep as their own. In return for a cash payment from a land company, a dummy settler would file a claim, live on the land for six months, buy it for an absurdly low price, and hand it over to his or her employer. Then the dummy settler would file another claim.

Congress abolished pre-emption in 1891. During the years the system was in force, about 200 million acres (81 million hectares) of land passed from the government to private owners. Dennis L. Thompson

Pregnancy, also called *gestation,* is the period when a female carries a developing baby within her body. The females of almost all species of mammals have a period of pregnancy before giving birth. In human beings, pregnancy normally lasts about nine months.

Pregnancy begins when an *egg* (female sex cell) and a *sperm* (male sex cell) unite in a woman's body. This union, called *conception,* forms a single cell called a *fertilized egg.* The fertilized egg attaches itself to the lining inside the woman's *uterus,* a hollow, muscular organ in the abdomen. During the next nine months, the egg develops within the uterus into a fully formed baby. From about the third week to the eighth week after conception, all the baby's major organs begin to form. During this time, the baby is called an *embryo.* From the ninth week until birth, the baby's body grows in size while its organs mature. During this period, the baby is called a *fetus.* Pregnancy ends when the baby passes out of the mother's body at birth.

This article discusses pregnancy and the experiences of the expectant mother up to the baby's birth. For detailed information on the development of the baby during pregnancy and on the birth process, see **Baby; Reproduction, Human;** and **Childbirth.**

Becoming pregnant

A woman usually becomes pregnant by means of sexual intercourse. In sexual intercourse, a man's penis discharges *semen*—fluid containing sperm—in the woman's vagina. Pregnancy begins if a sperm penetrates an egg.

In addition, scientists have developed techniques that enable women to become pregnant without sexual intercourse. For example, in a process called *in vitro fertilization,* sperm are collected from a man and used to fertilize eggs in a laboratory dish. The eggs are then inserted into the woman's uterus.

Planning for pregnancy. Medical experts recommend that women who plan to become pregnant seek medical advice before conception, as much as a year before pregnancy. A woman should choose a health care provider skilled in giving such advice and in providing medical care during pregnancy. This person may be either a physician who is qualified to care for pregnant women or a *nurse-midwife.* In the United States, a nurse-midwife is a registered nurse specially trained and certified to care for pregnant women.

During the initial pregnancy visit, the woman provides information about her present health, past illnesses and pregnancies, and her family medical history. The health care provider gives the woman a thorough physical examination and orders certain medical tests. For example, blood and urine tests check for diseases or conditions in the mother that can harm a developing baby, including anemia, hepatitis B, syphilis and other sexually transmitted diseases, and *rubella* (German measles). One important blood test determines if the mother and baby have the same *Rh factor,* a substance on red blood cells. If they have different Rh factors, the baby may develop a serious blood disorder. See **Rh factor.**

The doctor or midwife counsels the woman about risks to the pregnancy based on her health, habits, medical history, or age. Women who have certain disorders in their family histories or who are over 35 may be advised to seek additional counseling to determine the chances of bearing a child with genetic defects.

Confirming pregnancy. For the majority of women, the first sign of pregnancy is a missed *menstrual period.* A menstrual period is the time when a woman *menstruates* (discharges blood and tissue through the vagina). Each month, the lining of the uterus thickens in preparation for pregnancy. If the woman does not become pregnant, the lining breaks down and menstruation occurs. If the woman becomes pregnant, however, the thickened lining remains intact, helping to sustain the developing baby. As a result, menstruation stops after conception and resumes after the baby is born.

A woman who suspects she may be pregnant should have a pregnancy test as soon as possible. Pregnancy tests check for a hormone called *human chorionic gonadotropin* (hCG) in the woman's blood or urine. This hormone is first produced by the fertilized egg and later by the *placenta,* an organ that forms in a pregnant woman's uterus. The placenta enables the baby to

A childbirth class helps expectant mothers and their partners prepare for labor and delivery. Such classes provide a realistic preview of the birthing process and teach natural pain-control techniques for use during childbirth.

obtain food and oxygen from the mother's blood.

Blood tests performed in a laboratory can verify pregnancy as early as about seven days after conception. Women can test their urine for hCG using a home pregnancy test kit. Such tests are accurate beginning about the time of the woman's first missed menstrual period. However, a qualified health care provider should confirm the results of a home pregnancy test.

Estimating the date of birth. The health care provider uses the date of the expectant mother's last menstrual period to estimate when the baby will be born. The birth typically is calculated to occur 280 days, or 40 weeks, from the first day of the woman's last menstrual period. Throughout pregnancy, the estimated birth date may be adjusted somewhat based on the size of the uterus and other factors.

How pregnancy affects women

During pregnancy, a woman's body undergoes enormous changes. Many changes result from increased levels of the hormones *estrogen* and *progesterone* in the woman's blood. During pregnancy, these hormones are secreted into the bloodstream primarily by the placenta. The placenta also produces certain other hormones that trigger changes in a woman's body. To help describe when changes occur in the woman and her developing baby, pregnancy is often divided into three three-month periods called *trimesters.*

Weight gain. Women normally gain between 25 and 35 pounds (11 and 16 kilograms) during pregnancy. Several factors affect the amount gained, including a woman's weight at the start of pregnancy and the number of babies she is carrying. At birth, the baby accounts for about $6\frac{1}{2}$ to 8 pounds (3 to 3.5 kilograms) of the weight gained and the placenta about 1 to $1\frac{1}{2}$ pounds (0.5 to 0.7 kilogram). The rest of the weight is mainly fat, blood and other fluids, and extra tissue in the breasts and uterus.

Changes in breasts. A woman's breasts change in certain ways throughout pregnancy so that they can produce milk to feed the baby after birth. For example, the glands in the breasts that make the milk and the *ducts* (tubes) that carry the milk to the nipples both enlarge. The breasts themselves become larger and more tender. The *lactation* (milk-making) process begins soon after the baby is born.

Changes in the uterus prepare a woman's body for the birth process, also called *labor.* During labor, contractions of the uterus and abdomen push the baby out of the woman's body through the vagina.

The uterus expands to about 24 times its normal size during pregnancy, mostly because the muscle cells in the wall of the organ increase in size. Around the sixth month of pregnancy, the uterus begins to have irregular contractions that may be mild or intense.

Other common symptoms of pregnancy. During the first trimester, hormonal changes cause many women to experience *morning sickness* (nausea and vomiting). By about the fourth month, however, morning sickness usually lessens or disappears.

Many pregnant women experience increased fatigue and the need to urinate frequently. Hormonal changes, weight gain, and other changes in the woman's body contribute to fatigue. Frequent urination results mainly from the expanding uterus pressing on the bladder.

Other symptoms caused or made worse by the uterus pressing on organs include back pain, shortness of breath, discomfort in the pelvic region, heartburn, and constipation. In addition, *varicose veins* (enlarged veins in the legs) and *hemorrhoids* (enlarged veins around the anus) may occur.

Prenatal care

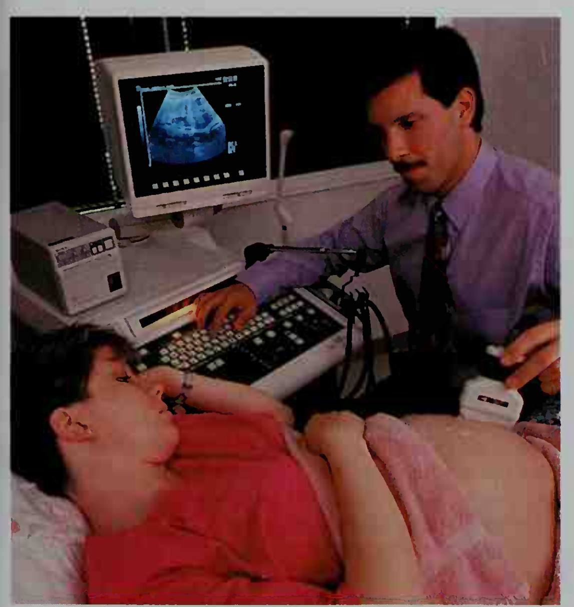
A pregnant woman's health and habits can affect the growth and development of her baby. The term *prenatal care* refers both to medical care during pregnancy and to an expectant mother's healthful lifestyle. Good prenatal care helps protect the health of the unborn baby.

Medical care. A woman who becomes pregnant should receive periodic physical examinations and tests.

Routine examinations. During each physical examination, the health care provider checks the mother's

weight, blood pressure, heart rate, and general physical condition. He or she listens to the baby's heartbeat and measures and feels the mother's abdomen to determine the growth and position of the fetus. Routine checkups also include a urine test to check for *preeclampsia,* a serious condition that can occur later in pregnancy, and *gestational diabetes,* a disorder that impairs the body's ability to use sugar normally.

Special tests. The health care provider may order one or more special tests. One of the most common of these is an *ultrasound examination.* In this examination, special equipment produces ultrasonic waves that reflect off the fetus. The returning echoes produce an image of the fetus on a screen. Ultrasound testing can help confirm the position and growth of the fetus and determine the number of babies the mother is carrying.



Special tests also may be given to determine whether the fetus has certain genetic defects, such as Down syndrome. In a test called *amniocentesis,* a physician takes a sample of the *amniotic fluid,* the watery liquid in the protective sac that forms around the baby. The fluid contains cells shed by the baby that can be tested for genetic disorders. In *chorionic villus sampling,* a sample of the placental tissue is analyzed for abnormalities. See **Amniocentesis; Genetic counseling.**

Lifestyle during pregnancy. In general, a pregnant woman should eat a well-balanced diet, get plenty of sleep, and exercise regularly at a mild or moderate level. Doctors also recommend taking extra amounts of certain vitamins and minerals. Expectant mothers should not eat undercooked meat. Such meat may contain parasites that cause *toxoplasmosis,* a disease that can severely damage a developing baby. A cat's body waste can also spread toxoplasmosis. As a result, pregnant women should not touch dirty cat litter.

Any chemical in the expectant mother's blood can enter the developing baby's bloodstream through the placenta. Some chemicals damage the developing baby or interfere with its growth. For this reason, pregnant women should not take medications, including over-the-counter drugs such as aspirin and nasal spray, unless advised to by a health care provider. Nonmedicinal drugs, alcoholic beverages, and cigarette smoke should also be avoided.

Pregnant women should avoid X rays and exposure to hazardous chemicals. They should also avoid excessive heat, such as in hot tubs or saunas. The body's effort to keep cool in such heat can result in blood—and therefore oxygen—being drawn away from the uterus.

A pregnant woman can help herself, as well as her baby, by learning about labor and delivery. Childbirth classes provide a realistic preview of the birth process and teach natural pain-control techniques, such as breathing and relaxation. These methods can reduce or eliminate the need for pain medication during labor.

Kevin Beebe, Custom Medical

An ultrasound examination uses sound waves to produce an image of the fetus on a computer screen. Such testing can confirm the position and growth of the fetus.

Complications

Common complications of pregnancy include (1) miscarriage, (2) ectopic pregnancy, (3) preeclampsia, and (4) premature birth.

Miscarriage, also called *spontaneous abortion,* is the unintentional early ending of pregnancy by a natural cause before the 20th week of pregnancy. In a miscarriage, the embryo or fetus is expelled from the body by contractions of the uterus. More than 20 percent of pregnancies end in miscarriage. The majority of miscarriages occur during the first trimester.

Abnormalities in the embryo or fetus cause most miscarriages. Physical problems in the expectant mother also cause many miscarriages. Such problems, which usually cause more miscarriages later in the pregnancy than do fetal abnormalities, include infections; disorders of the immune system, cervix, or uterus; and diabetes or other diseases. Medical care before and during pregnancy can prevent some miscarriages.

An ectopic pregnancy occurs when a fertilized egg implants itself outside the uterus, usually inside the *fallopian tube,* the tube through which the egg passes on its way from the ovary to the uterus. The developing baby cannot survive in an ectopic pregnancy. The pregnancy may be fatal to the mother if untreated.

Preeclampsia, *PREE uh KLAMP see uh,* formerly called *toxemia of pregnancy,* is one of the most serious conditions that can occur during the later months of pregnancy. Its cause is unknown. Physical symptoms include high blood pressure, headaches, sudden and excessive weight gain, and swelling, especially of the face, feet, and hands. If untreated, preeclampsia can lead to *eclampsia,* a condition that can result in the death of the mother, the baby, or both.

Premature birth. Some infants are born *prematurely*—that is, before the 37th week. The more premature a baby is, the less it weighs and the higher its risk of death. A pregnant woman can lessen the risk of some premature births by good prenatal care.

Prehistoric animal

Prehistoric animal refers to any animal that existed more than 5,500 years ago, before human beings began recording their history in writing. Some prehistoric animals greatly resembled their present-day relatives. Many ancient creatures, however, were unlike anything alive today. Dinosaurs rank among the best-known prehistoric animals. One dinosaur, *Seismosaurus* (pronounced *SYZ muh SAWR uhs),* may have grown up to 150 feet (45 meters) in length. Other unusual creatures included flying reptiles, sea scorpions 8 feet (2.4 meters) long, and hairy relatives of elephants called *mammoths.* Not all of these animals lived at the same time.

The long history of animals is recorded by *fossils.* Fossils are the remains of prehistoric life. They include the bones, shells, and tracks of animals, as well as petrified wood and impressions of leaves. Fossils help scientists called *paleontologists* learn what prehistoric animals looked like and when, where, and how they lived. Paleontologists use fossils to compare prehistoric animals with living ones. Such comparisons help people understand how ancient and modern animals are related.

The oldest known animal remains date from about 600 million years ago. However, some paleontologists think that simple, tiny animals may have existed much earlier, perhaps as early as 1 billion years ago.

The world of prehistoric animals

Most animals have developed during a time in the earth's history that scientists call the Phanerozoic Eon, which means "time of visible animal life." It began about 544 million years ago and continues to the present day. Scientists divide the Phanerozoic Eon into three *eras:* (1) the Paleozoic Era, which lasted from about 544 million to 248 million years ago; (2) the Mesozoic Era, which lasted from 248 million to 65 million years ago; and (3) the Cenozoic Era, which began 65 million years ago and continues today. Throughout each era, climates kept changing, continents drifted and changed in outline, mountains rose up and were leveled, and sea levels rose and fell. These changes helped determine which living things survived and which died out.

Each of the three eras is divided into shorter intervals called *periods.* Periods, in turn, can be divided into still shorter intervals called *epochs.* Different layers of rock with different kinds of fossils formed during each period. Such rocks help scientists understand how the earth's surface and climates have changed. The fossils tell paleontologists what animals and plants lived during each period.

Early forms of animal life

Animal life evolved and flourished only after plants became available as food. Like animals today, prehistoric animals depended on green plants. Green plants can use energy from sunlight to make food. Animals cannot do so. They must eat either plants or plant-eating animals.

Hans-Dieter Sues, the contributor of this article, is Senior Curator of Fossil Vertebrates at the Royal Ontario Museum.

Prehistoric animals included some of the most unusual creatures that ever lived. This fossil skeleton belonged to a giant ground sloth. This huge, plant-eating mammal was nearly as tall as a house, standing 14 $\frac{1}{2}$ feet (4.4 meters) tall on its hind legs.

The earliest animals lived in the seas and were probably tiny. Although their bodies were small, they were made up of many cells. Some groups of those cells became adapted for feeding or reproduction, while others helped the animals move and detect changes in their environment.

The first animals are known from fossils preserved in rocks about 600 million to 570 million years old. They include jellyfishes, worms, and leaflike creatures called *sea pens.* All these creatures were *invertebrates*—that is, they had no backbones. Their soft bodies also lacked shells or other hard parts. As a result, few of them were preserved as fossils.

According to fossils found by scientists, animals first become abundant at the beginning of the Paleozoic Era. A tremendous variety of invertebrate animals suddenly developed in the oceans during this time. Unlike earlier animals, many of these creatures had hard shells or tough outer frames to protect them from enemies.

Trilobites ranked among the most common early Paleozoic animals. They were ancient *arthropods,* the group to which spiders and crabs belong. Most trilobites fed on small food particles from the sand or mud on which they lived. Such food may have included small worms and other bottom-dwelling animals. Another common group of Paleozoic animals, the *brachiopods,* had shells

similar to those of clams. They lived on the sea floor or burrowed in the mud. Brachiopods ate tiny organisms. They fed by opening their shells and filtering food from the water with a comblike organ.

The first animals with backbones, called *vertebrates,* probably appeared at the end of the Cambrian Period, more than 500 million years ago. The earliest vertebrates were small. Plates of bone usually protected their heads and much of their bodies. In later vertebrates, a skeleton made up of many bones formed inside the body. The skeleton provided a solid internal frame to which muscles could attach.

The earliest vertebrates had mouths without jaws. They most likely fed on small bits of dead animals or tiny creatures on the sea floor or in the water. In the Silurian Period, beginning 440 million years ago, vertebrates developed bony jaws and teeth. These mouth parts enabled them to catch and consume larger kinds of food. The vertebrates also developed movable paired fins, enabling them to become more active swimmers.

The Devonian Period, often called the *Age of Fishes,* began about 410 million years ago. One of the largest Devonian fishes, *Dunkleosteus (DUHNK uhl AHS tee uhs),* grew 23 feet (7 meters) long. Massive plates of bone protected *Dunkleosteus's* head and the front of its body. Its jawbones formed sharp edges for cutting up and eating smaller fish.

Bony fishes of the Devonian Period had two types of fins, *rayed* and *lobed.* Rayed fins consist of a web of skin supported by a skeleton of rods called rays. Fish with this type of fin, known as *ray-finned fishes,* are fast swimmers. Lobed fins consist of a fleshy stalk fringed with rays. The Devonian Period was the time of greatest abundance for fishes with this type of fin, called *lobe-finned fishes.* Lobed fins enabled the creatures to crawl along the bottom of the sea or over land. Many lobe-finned fishes also had lungs with which they gulped air when there was not enough oxygen in the water. All land-living vertebrates, including human beings, descended from these fishes.

The move onto land. Animals first established themselves on dry land by the beginning of the Devonian Period. The oldest known land animals were arthropods, including scorpions, spiders, and mites. Vertebrates probably first moved onto land near the end of the Devonian Period. The sturdy fins of lobe-finned fishes evolved into the legs of land-living vertebrates, with ankles, wrists, fingers, and toes suitable for leaving the water. Lungs became full-time suppliers of oxygen.

Four-footed land vertebrates are known as *tetrapods (TEHT ruh pahdz).* The first tetrapods, called *amphibians,* had to return to the water to lay eggs. These eggs were enclosed in a jellylike substance that, if left on land, would dry out and kill the eggs. Thus amphibian eggs developed and hatched in water, where the young lived until they changed into land-dwelling, air-breathing adults. During the late Paleozoic Era, a great variety of amphibians inhabited the shores of lakes and rivers, dividing their lives between land and water. Modern amphibians, including frogs and toads, are small, but some Paleozoic amphibians were large. The meat-eating *Eryops (UR ee ahps)* grew more than 5 feet (1.5 meters) long and had a big head. Others, such as *Ophiderpeton (oh fee DURP uh tahn),* were small and snakelike.

The earliest insects were wingless and appeared during the Devonian Period. By the late Carboniferous Period, about 300 million years ago, many insects had developed wings. They included *Meganeura (mehg uh NYUR uh),* a spectacular animal resembling a dragonfly. It had a wingspan of up to 26 inches (65 centimeters).

The first reptiles evolved from amphibians during the Carboniferous Period. Reptiles had an important advantage over earlier land-living vertebrates: they could lay their eggs on land. Reptile eggs were protected by a hard leathery shell that prevented them from drying out. Special membranes inside the eggs enclosed and protected the developing young in a fluid-filled chamber. This type of egg enabled reptiles to live entirely on land.

The Age of Reptiles

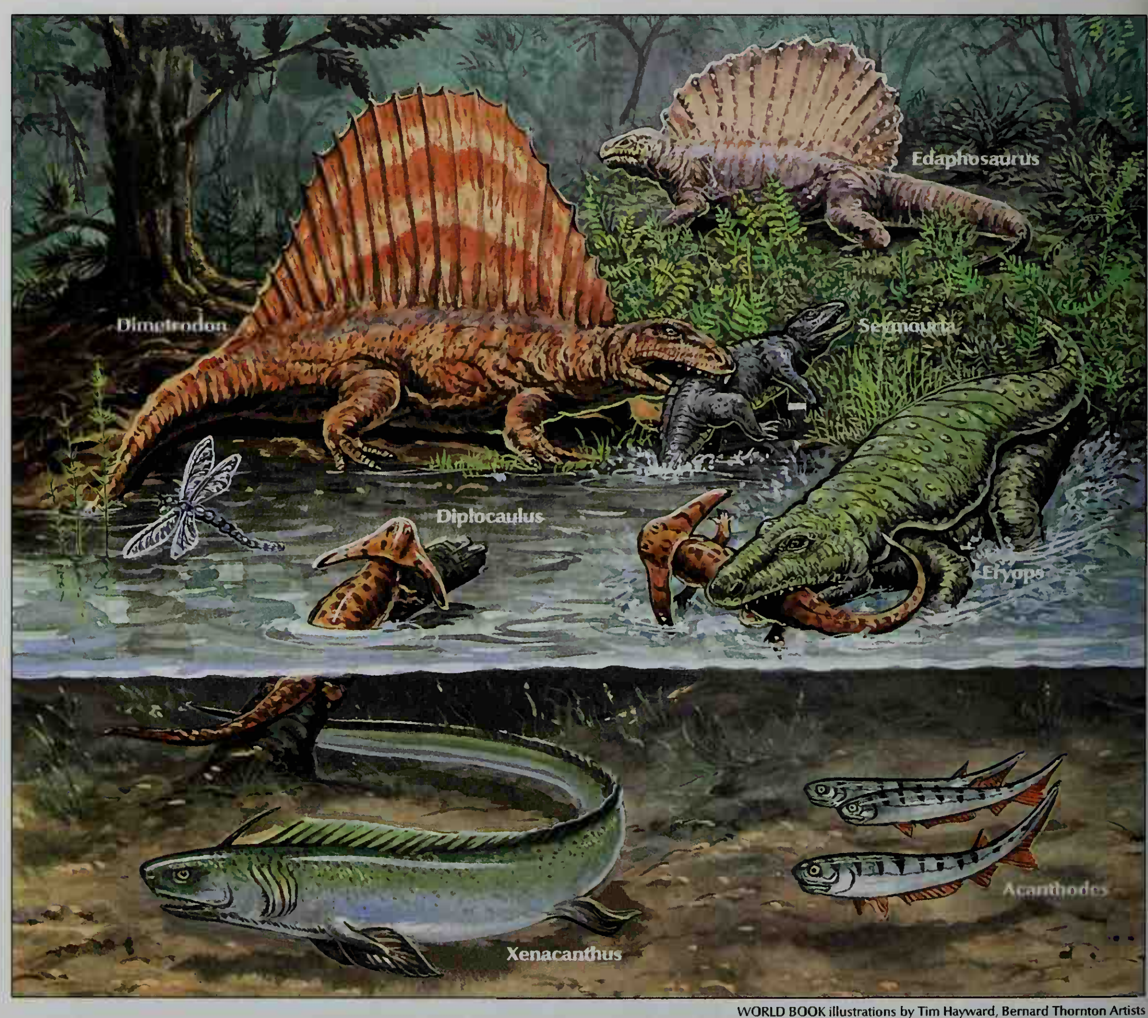
During the Permian Period at the end of the Paleozoic Era, the earth's climate generally grew warmer and drier. Deserts spread over large areas, displacing many amphibians that needed water for their survival. At the end of the period, about 248 million years ago, the seas shrunk as sea levels dropped severely worldwide. This lowering of the sea level helped cause one of the earth's largest known extinctions. Ninety-five percent of species may have perished in the seas at that time. But reptiles survived the new conditions on land and sea. Thus these animals came to dominate the earth throughout most of the Mesozoic Era, which lasted from about 248 million years ago to about 65 million years ago. This era is often called the *Age of Reptiles.*

Dinosaurs ranked as the dominant reptiles of the Mesozoic. They varied greatly in size, including some of the largest animals that ever lived. The longest was the plant-eating *Seismosaurus,* which may have measured about 150 feet (45 meters) in length. The smallest fully grown dinosaurs grew to about 3 feet (1 meter) in length. Many large dinosaurs were probably slow-moving. But scientists believe some dinosaurs, such as *Ornithomimus (awr NIH thuh MY muhs),* could run fairly fast. For more information about dinosaurs, see **Dinosaur.**

Other reptiles. While dinosaurs ruled the land, many kinds of large reptiles inhabited the sea and air. Sea-dwelling reptiles included *ichthyosaurs (IHK thee uh sawrs),* which resembled dolphins in shape and probably could swim fast. *Mosasaurs (MOH suh sawrs)* were enormous sea lizards that lived during the late Cretaceous Period, which ended about 65 million years ago. They grew up to 30 feet (9 meters) long. *Plesiosaurs (PLEE see uh sawrs)* had four large flippers and a short tail. Many plesiosaurs also had an extremely long neck.

Flying reptiles called *pterosaurs (TEHR uh sawrz)* became the first vertebrates to evolve flapping flight, the kind of flight later used by most birds. Each of a pterosaur's wings consisted of a membrane of skin supported by a long finger made of hollow bones. Pterosaurs had no feathers, but hairlike structures probably covered their bodies. Some pterosaurs ranked as the largest flying animals of all time, reaching a wingspan of 40 feet (12 meters).

Invertebrates flourished during the Age of Reptiles, and many new kinds appeared. Numerous species of mollusks lived in the seas. They included clams, snails, squids, and *ammonites,* which formed spiral-shaped shells. *Crustaceans,* including lobsters, crabs, and



shrimp, became common in the oceans during the Cretaceous Period. All major present-day groups of insects had evolved by Cretaceous times.

Fish remained abundant in the Mesozoic Era. The first modern kinds of bony fish, called *teleosteans (TEHL ee AHS tee uhnz* or *TEE lee AHS tee uhnz)*, evolved near the end of the Triassic Period, about 213 million years ago.

Amphibians. Many of the larger amphibians had died out by the end of the Triassic Period. But some kinds persisted well into the Cretaceous Period. Smaller amphibians, including frogs and salamanders, first appeared at the beginning of the Jurassic Period, around 213 million years ago.

Birds evolved from small meat-eating dinosaurs during the Jurassic Period. The oldest known bird, *Archaeopteryx (AHR kee AHP tuhr ihks)*, lived around 145 million years ago. It grew to about the size of a crow. *Archaeopteryx* was covered with feathers, but it resembled reptiles in many features. It had teeth, a long tail, and three grasping, clawed fingers on each wing.

Period	Cambrian	Ordovician	Silurian	Devonian	Carboniferous	Permian
Began	544 million years ago	505 million years ago	440 million years ago	410 million years ago	360 million years ago	286 million years ago

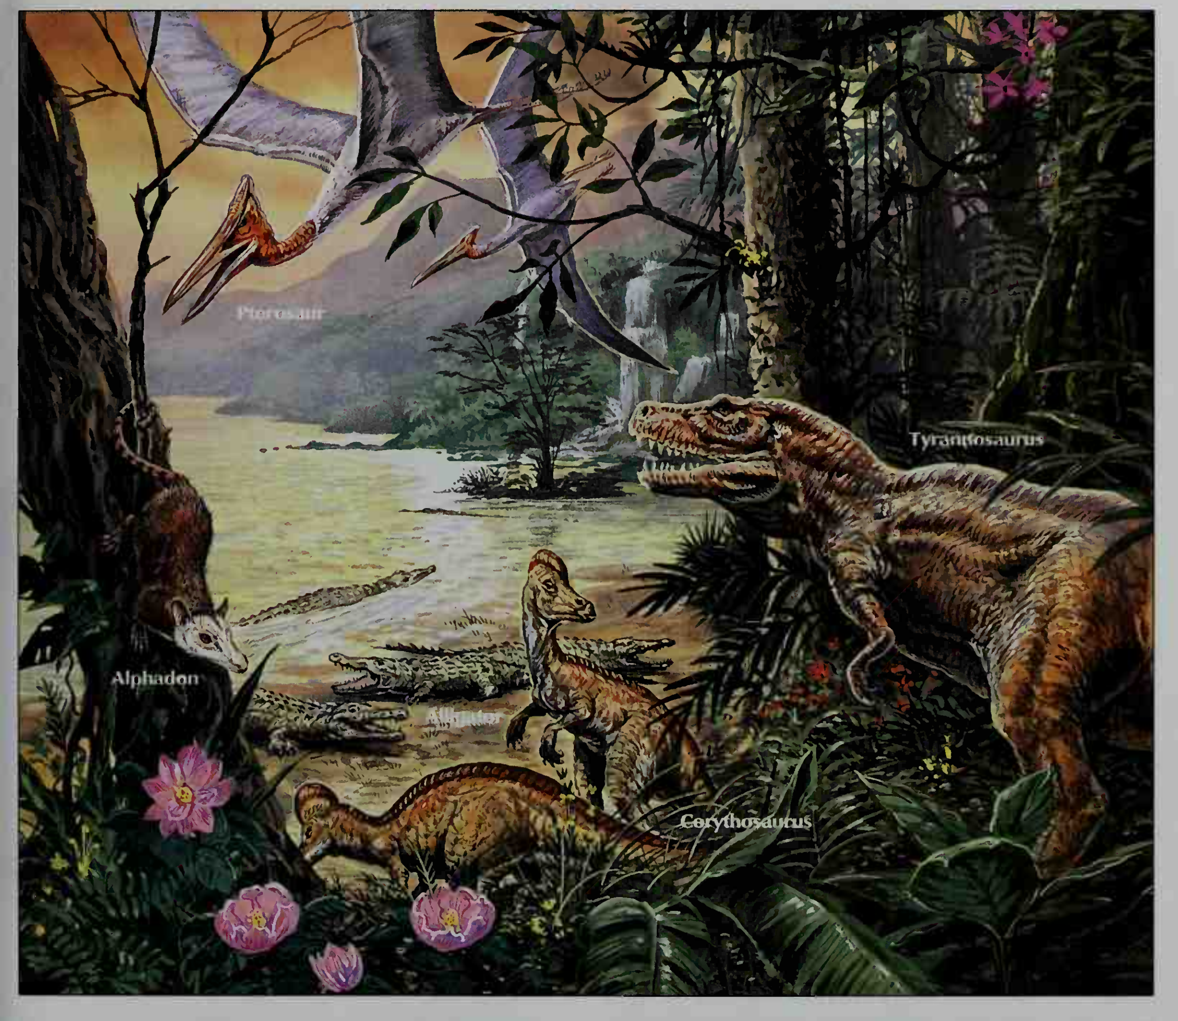
Animal life	Trilobites were common in the sea. Jawless fish appeared. Land was bare.	Mollusks and coral were plentiful in the sea. Algae became common.	Fish developed jaws. Plants appeared on land.	Fish were plentiful. Insects and amphibians appeared.	Crustaceans, fish, and amphibians were plentiful. Reptiles appeared. Huge, swampy forests grew. Giant insects lived in the forests.	Seed plants appeared. Trilobites died out near the period's end.

WORLD BOOK illustrations by Tim Hayward, Bernard Thornton Artists



Animal life of the Paleozoic Era included an abundance of species. Animals from the Permian Period at the end of that era, *shown here*, included *Dimetrodon* and *Edaphosaurus*, which had large saillike fins on their backs. Such amphibians as the large *Eryops*, triangular-headed *Diplocaulus*, and smaller *Seymouria* lived on land and sea. Large insects and fish were also common.

The first modern birds appeared in the Cretaceous Period. They developed a toothless beak covered by hornlike material. The tail became short, and the fingers fused into a single structure supporting the wing.

Mammals evolved from mammallike reptiles near the close of the Triassic Period. The first mammals were small, about 6 inches (15 centimeters) long, and probably ate insects and other small animals. These mammals likely had hair covering their bodies. Like their modern descendants, ancient mammals suckled their young from special milk glands. Most Mesozoic mammals probably laid eggs as their reptile ancestors had done. Today, the only egg-laying mammals, called *monotremes,* are the duck-billed platypus and the echidnas of Australia and New Guinea.

The two major groups of mammals, *marsupials* and *placentals,* first developed in the Cretaceous Period. Both these groups give birth to live young. Marsupial young are born in an underdeveloped state. The young crawl into a special pouch on the mother's belly, where

Period	Triassic	Jurassic	Cretaceous
Began	248 million years ago	213 million years ago	145 million years ago

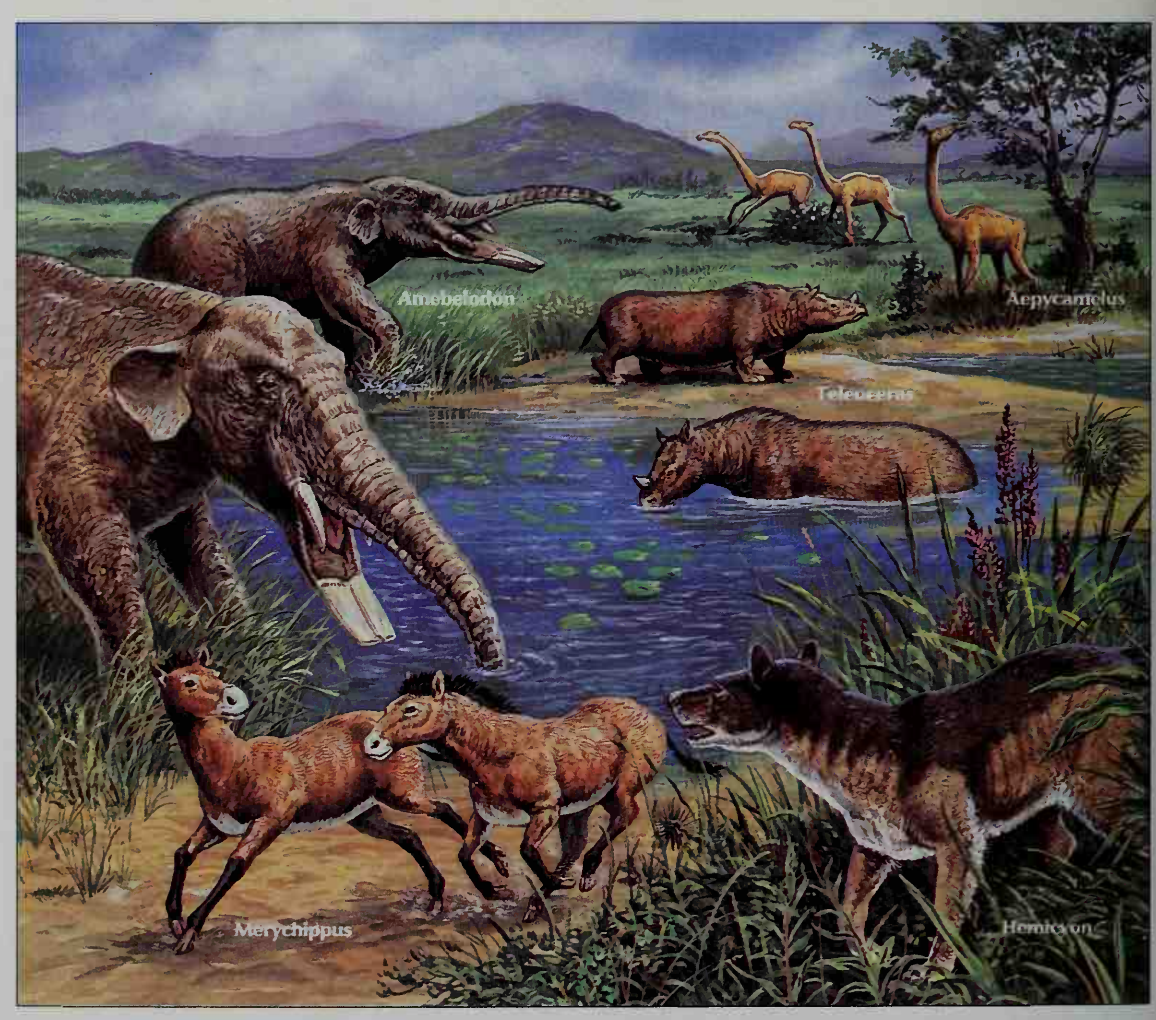
Animal life	The first turtles, crocodiles, dinosaurs, sea reptiles, flying reptiles, and mammals appeared. The huge supercontinent began to break up into separate continents.	The first birds appeared. Dinosaurs reached their greatest size. Insects were plentiful. Ammonites flourished in the sea. A few small mammals lived on land.	Horned and armored dinosaurs became common. Flowering plants developed. Dinosaurs, flying reptiles, and giant sea reptiles died out at the end of the period.

Reptiles dominated the Mesozoic Era, ruling the land, sky, and sea. The illustration above shows animals from the Cretaceous Period. They include the huge meat-eating dinosaur *Tyrannosaurus* and the plant-eating duckbilled dinosaur *Corythosaurus.* Other reptiles besides dinosaurs included flying pterosaurs and early aquatic alligators. Early mammals ,such as *Alphadon,* also lived during this time.

they continue to develop and grow. Most early marsupials resembled modern opossums.



Placentals give birth to fairly well-developed young. These young grow inside the mother's body, where they receive nourishment from a special organ called the *placenta.* Many early placentals resembled shrews.

The Age of Mammals

By the end of the Mesozoic Era, some 65 million years ago, dinosaurs and other dominant reptiles had become extinct. Scientists have found evidence that a huge asteroid hit the earth about 65 million years ago. Dust from the impact of this asteroid, as well as soot from the wildfires caused by the impact, would have blocked sunlight from reaching the earth's surface. Lack of sunlight would have lowered temperatures worldwide and killed many of the plants and animals that dinosaurs ate.

The Cenozoic Era, also called the *Age of Mammals,* followed the Mesozoic Era and continues today. During this new era the climate grew gradually cooler and drier,

Period	Tertiary					Quaternary	
Epoch	**Paleocene**	**Eocene**	**Oligocene**	**Miocene**	**Pliocene**	**Pleistocene**	**Holocene**
Began	65 million years ago	56 million years ago	34 million years ago	24 million years ago	5 million years ago	2 million years ago	11,500 years ago
Lasted	9 million years	22 million years	10 million years	19 million years	3 million years	2 million years	11,500 years
Animal life	The kinds of mammals expanded rapidly.	First camels, horses, and other mammals appeared.	Grassland spread. Primitive apes appeared.	Mammals reached their greatest variety.	Humanlike creatures and many modern mammals appeared.	Modern human beings developed. Ice ages occurred.	Human beings hunted and tamed many animals.

Mammals ruled the earth during the Cenozoic Era. This illustration shows mammals that lived in the Miocene Epoch. Some of them resembled their present-day relatives, such as the elephantlike *Amebelodon,* the early rhinoceros *Teleoceras,* and the ancient horse *Merychippus.* Others resembled modern mammals that are not close relatives. The doglike *Hemicyon* was actually an early bear.

and mammals became the dominant animals on the earth. All mammals have warm-blooded bodies covered with hair and are equipped with a variety of teeth for chewing food. Warm-bloodedness, which keeps the mammals' bodies at constant high temperatures, probably enabled early mammals to adapt more easily than other vertebrates to the cooler, drier climates of the Cenozoic Era.

The development of placentals. Most of the world's modern placentals probably evolved at the beginning of the Cenozoic Era. These creatures had small bodies. For example, *Miacis (MY ah sihs),* a forerunner of all meat-eating mammals, grew about as large as a weasel. The ancient horse *Hyracotherium (HY ruh koh THEER ee uhm),* also called *Eohippus (EE oh HIHP uhs),* stood no taller than a dog. Primates started out as small creatures but later evolved into monkeys, apes, and human beings. One of the earliest whales, *Pakicetus (pak ee SEE tuhs),* grew only about 6 feet (1.8 meters) long. Its descendants, however, became some of the earth's largest animals.

By the middle of the Cenozoic Era, many forests had disappeared. Grasslands spread across many parts of the world, and climates grew cooler and drier. Such hoofed mammals as deer and horses developed teeth suitable for feeding on grass. Many hoofed mammals also had long, slender legs, enabling them to run fast to escape from predators in open country.

The great increase in plant-eating mammals provided abundant prey for meat-eating mammals. These meat-eaters included the earliest dogs and the saber-toothed cats, large lionlike predators that could kill their prey with huge fanglike teeth. In Africa and Asia, the first apes evolved. Many new species of rodents appeared, and they quickly became the most common small mammals.

The distribution of mammals. About 250 million years ago, all the continents drifted together to form one huge land mass, the supercontinent *Pangaea.* Around 200 million years ago, Pangaea began to break up again into separate continents, which slowly moved to their present positions.

Placental and marsupial mammals may have developed on the northern continents. When Australia separated from South America and Antarctica at the beginning of the Cenozoic, many marsupials and probably only a few placentals had spread there. With few placentals to compete with for food and nesting sites, many kinds of marsupials evolved only in Australia. Some marsupials resembled placental mammals in appearance and habits. They included *Diprotodon (dy PROH tuh dahn),* which resembled a hippopotamus, and the doglike Tasmanian wolf. *Procoptodon (proh KAHP tuh dahn)* and other early kangaroos developed a plant-eating way of life similar to that of hoofed placentals.

Both marsupials and placental mammals spread to South America during the Cretaceous Period. But at the end of that period, South America became separated from the rest of the world for about 60 million years. As a result, many unique kinds of mammals developed on that continent. Prehistoric South American marsupials included the *Thylacosmilus (THY luh koh SMY luhs),* a predator that looked like a saber-toothed cat, and *Borhyaena (bor hy EE nuh),* which resembled a wolf. Placental mammals in South America included armadillos and huge ground sloths.

About 3 million years ago, a land connection formed between North and South America. Many North American mammals moved to South America, causing the extinction of numerous South American marsupials and placentals. But some South American mammals migrated in the opposite direction and settled in North America. These included the opossum, a marsupial, and the porcupine, a placental.

The development of other animals. All major groups of modern amphibians and reptiles had evolved by the Cretaceous Period and survived the great extinction 65 million years ago. Among reptiles, lizards and snakes became common. Many birds developed during the Cenozoic Era. They included the flightless *Diatryma (DY uh TRY muh),* which grew about 7 feet (2 meters) tall.

The ice ages. A few million years ago, the climate grew colder on the northern continents. This led to a series of ice ages during the Pleistocene Epoch, which occurred about 2 million to 11,500 years ago. During these ice ages, glaciers repeatedly spread and retreated over large areas of North America, Europe, and Asia. One of the most prominent mammals of this period, the elephantlike mammoth, roamed the frozen plains of the Northern Hemisphere. Its thick coat of dense, long hair helped keep it warm.

Many large placental mammals died out before the last glaciers retreated about 11,500 years ago. In North America, these included giant ground sloths, saber-toothed cats, and mammoths. Some scientists believe many large mammals were hunted to extinction by prehistoric people, but others argue that the animals disappeared because of changes in climate and plant life.

Prehistoric human beings lived only a short part of the earth's long history. Most scientists now think that prehistoric people evolved from humanlike apes between about 10 million and 5 million years ago.

The study of prehistoric animals

Interpreting fossil evidence. Fossils provide paleontologists with a record of prehistoric animals and plants and the environments in which they lived. On rare occasions, entire prehistoric creatures are preserved as fossils. Most fossils, however, consist of such hard body parts as shells, bones, and teeth.

Paleontologists must compare fossils with animals that live today to learn about prehistoric creatures. For example, scientists can estimate an ancient mammal's size and weight by comparing the shape and size of its leg bones with leg bones of related modern mammals. Fossils also reveal information about an animal's way of life. Prehistoric animals with long legs probably were fast runners, just like animals with long legs today, whereas animals with short, stout legs moved more slowly. By measuring the distance between a dinosaur's fossilized footprints, paleontologists can calculate how fast the animal moved. The shape of fossil teeth can show what type of food a prehistoric animal ate. The teeth of meat-eaters have sharp edges for cutting and slicing through meat, while plant-eaters often have broad, blunt teeth for grinding plant material, which may include tough fibers.

Fossils show that many prehistoric animals have de-

scendants that still exist today. Birds are the closest living relatives of dinosaurs. Bird skeletons resemble the skeletons of meat-eating dinosaurs more closely than they resemble those of any living animal.

Evolution and extinction. According to the *theory of evolution,* organisms adapt to changes in their environment by developing new characteristics. These characteristics increase their chance to survive and flourish under the changed conditions. The study of fossils provides important evidence for evolution. Fossils show that living beings usually have developed from simpler organisms throughout the earth's long history.

Much evolutionary change is gradual, producing a kind of extinction called *background extinction.* In background extinction, old species slowly die out as new ones evolve. But during a *mass extinction,* many different kinds of plants and animals suddenly die out. The most famous mass extinction occurred at the end of the Cretaceous Period, when dinosaurs and countless other living things disappeared.

Some paleontologists believe a collision of an asteroid with the earth caused each mass extinction. But according to other scientists, this theory may not explain why many animals survived such events. They think an overall change in the earth's climate caused most large extinctions. A general rise or fall in temperature or a change in the amount of rainfall could create conditions in which some species die off and others adapt and survive. Extinctions may also result after animals move across a newly formed land bridge into a new area. The newcomers may compete successfully for food with animals already living there, thus killing off the native species.

By studying why prehistoric extinctions occur, scientists may learn more about why species are disappearing today. Up to 99.9 percent of all animal species that have ever existed are now extinct.

Prehistoric people are the ancestors of modern human beings. This illustration is an artist's idea of how one type of prehistoric people, *Homo erectus,* may have learned to use fire. Cultural advances, such as the use of fire and clothing, helped *Homo erectus* spread to much of the world.

Prehistoric people

Prehistoric people are human beings who lived before writing was invented about 5,500 years ago. Writing enabled people to record information they wished to save, including descriptions of events in their lives. In this way, the invention of writing marked the beginning of history. The period before human beings learned to write is called *prehistory,* and people who lived during this period are known as *prehistoric people.*

Most scientists believe the first human beings lived about 2 million years ago. But early people probably arose from prehuman ancestors who first lived over 4 million years ago. These ancestors were small, humanlike creatures who walked erect. This article will discuss both prehistoric people and their near ancestors.

Scientists first discovered evidence of prehistoric people during the mid-1800's. Most of this evidence consisted of ancient, sharp-edged tools that prehistoric people had made of stone. The first fossilized bones of prehistoric people were also found during this time.

As scientists collected fossils of prehistoric people, they began to form a clearer picture of what early people looked like. For example, scientists learned from fossil evidence that early human beings had smaller brains than most modern people have. This evidence indicated to many scientists that human beings had *evolved*—that is, modified their physical structure over time. Scientists formed a set of ideas about human origins called the theory of human evolution. This theory states that as the environment of the prehistoric world changed, the prehuman ancestors of prehistoric people underwent a series of changes that resulted in the first human beings. They, in turn, evolved into modern human beings.

Today, many kinds of scientists work together to learn about prehistoric people. Physical anthropologists examine the fossilized bones and teeth of prehistoric people and their prehuman forerunners. They study these objects to learn more about what our ancestors looked like, how long they lived, and what foods they ate. Archaeologists search for and examine evidence, such as pottery and tools, to help explain how prehistoric people lived. Botanists study the remains of prehistoric plants, and zoologists analyze fossils of animals that lived when prehistoric people did. Geologists study the rock in which fossils are found. All these scientists are

called anthropologists if their chief concern is the study of human physical and cultural development.

Evidence of prehistoric people—such as fossils, tools, and other remains—is rare and often fragmented. Evidence of the earliest types of prehistoric people is the most difficult to find. Anthropologists must base their theories on this extremely limited evidence. As a result, scientists cannot yet present a detailed picture of early human life. In addition, new discoveries sometimes disprove theories that scientists already hold. For example, in 2000 and 2001, scientists in Kenya announced the discovery of fossil bones from two new humanlike species, *Orrorin tugenensis* and *Kenyanthropus platyops.* In 2002 in Chad, a fossil from another humanlike species was discovered. This fossil, from the new species *Sahelanthropus tchadensis,* is about 7 million years old. Scientists are studying these fossils to determine how these new species are related to other human ancestors.

Prehuman ancestors

Most scientists believe that human beings and apes—such as chimpanzees and gorillas—share a common ancestor. To support this theory, scientists point out that the fossilized remains of ancient humanlike beings and apes reveal many similarities, including similar brain sizes. In addition, studies comparing the physical structure, blood, and genetic material of modern human beings with those of apes show that people are more similar to apes than to any other living animal.

The ancestors of human beings probably began evolving separately from the ancestors of apes between about 10 million and 5 million years ago. This evolutionary split marks the beginning of the development of *hominids.* Hominids make up the scientific family that consists of human beings and early humanlike ancestors.

Where and when they lived. The earliest known hominids were a species called *Ardipithecus ramidus.* The name *Ardipithecus* comes from words in the Afar and Greek languages that mean *ground ape.* These creatures lived in Ethiopia in northeast Africa about 4,400,000 years ago. Scientists know little about them except that, like all hominids, they stood and walked on two legs.

© John Reader, SPL from Photo Researchers

Footprints of a prehuman ancestor were found at Laetoli, in Tanzania. These footprints, which were fossilized in volcanic ash, provide evidence that early hominids walked upright.

A much better-known group of early hominids are the *australopithecines* (pronounced *aw stray loh PIHTH uh seenz).* They first appeared about 4 million years ago in Africa. Fossil evidence suggests that these creatures became extinct between 2 million and 1 million years ago, about when the first human beings appeared.

Scientists have found australopithecine fossils in eastern, southern, and north central Africa. Most scientists believe that hominids originated in Africa and that prehistoric people later spread to other parts of the world.

What they looked like. The australopithecines looked much different from modern human beings. In some ways, such as in their facial features, they may have resembled chimpanzees. But they could stand upright and walk on two legs, and their canine teeth were much smaller and less pointed than those of apes.

The australopithecines had large faces that jutted out. Their brains were about one-third the size of modern human brains. Their molars were large, flat, and suitable for grinding food. Anthropologists believe from the shape of these creatures' teeth and from chemical analysis of their bones that they ate such foods as fruits, vegetables, nuts, seeds, insects, and small animals.

Types of australopithecines. The australopithecines belonged to the genus *Australopithecus,* a term that means *southern ape.* Most scientists have divided the genus into at least five species based on differences in the creatures' overall size, in the shape and size of their jaws and teeth, and in the size of their brains. The five species are (1) *A. anamensis,* (2) *A. afarensis,* (3) *A. africanus,* (4) *A. boisei,* and (5) *A. robustus.*

The earliest known species of *Australopithecus* was *A. anamensis,* which appeared in eastern Africa around 4 million years ago. Another *Australopithecus* species, *A. afarensis,* appeared about 3,700,000 years ago. One of the most complete australopithecines that scientists have found is a partial skeleton of a female *A. afarensis.* It was found at Hadar, Ethiopia. Scientists estimate that this creature, nicknamed "Lucy," was a little more than 3 feet (90 centimeters) tall and weighed about 60 pounds (27 kilograms). Scientists also have discovered the fossilized footprints of three *A. afarensis* individuals at Laetoli, in Tanzania. The footprints resemble those of modern people and show that *A. afarensis* walked as we do, fully supported by two legs. *A. afarensis* had about the same size brain that a chimpanzee has.

By about 3 million years ago, another australopithecine, *A. africanus,* was living in southern Africa. These creatures had rounder skulls and slightly larger brains than those of *A. afarensis.* In 1998, a complete *A. africanus* skeleton was discovered at Sterkfontein, a fossil site near Johannesburg, in South Africa.

During the time of *A. africanus,* two more australopithecine species appeared. One of them, *A. boisei,* lived in eastern Africa. The other, *A. robustus,* lived in southern Africa. Scientists call these two species the *robust* australopithecines. They had larger molars and more powerful jaws than the other three *Australopithe-*

Institute of Human Origins

The skeleton of "Lucy," a prehuman ancestor, is one of the most complete australopithecine fossils that scientists have found. This creature lived about 3 million years ago.

cus species, and may have had larger bodies. But their brain size was about the same as that of *A. africanus.* The earlier three species are called *gracile* (slender) australopithecines. The robust species probably became extinct between 1 $\frac{1}{2}$ million and 1 million years ago.

Scientists are uncertain about the precise relationships between the *Australopithecus* species. Some think the gracile species evolved one after the other, from the earliest, *A. anamensis,* to the latest, *A. africanus.* According to this theory, the two robust species formed an evolutionary side branch. Other scientists think the australopithecine species were linked differently. They believe that early in australopithecine evolution, these creatures spread to different parts of Africa, changing to adapt to their new environments. As a result, different species developed in different environments.

The first human beings

Most anthropologists believe the first people evolved from an australopithecine about 2 million years ago. The oldest tools scientists have found date from about that time. But because no hominid fossils were found with these tools, scientists do not know whether an australopithecine or an early human being made them.

Most prehistoric tools that have been found are made of stone. Thus, this period is called the Stone Age. Early toolmakers may also have used wood and other materials, but no tools made of those materials have survived. The Stone Age lasted from the first use of stone tools until bronze replaced stone as the chief toolmaking material. In some areas, this occurred about 3000 B.C.

The first part of the Stone Age is called the Paleolithic Period. It began over 2 million years ago and lasted until about 8000 B.C., when some people in the Middle East began farming. Even after these people learned to farm, many others continued to live by gathering wild plants and by hunting. These Stone Age hunters and gatherers who lived after 8000 B.C. are called *Mesolithic* people. Farmers from this period are called *Neolithic* people.

Three species. The first human beings lived in Africa about 2 million years ago. Anthropologists have found important fossils of these people near the shores of Lake Turkana in Kenya and in Olduvai Gorge in Tanzania. Many scientists divide these people into three species—*Homo habilis, Homo rudolfensis,* and *Homo erectus.*

Homo habilis had a brain larger than an australopithecine brain but only about half the size of a modern human brain. *Homo habilis* also had smaller molars and a less protruding face than the australopithecines had. The Latin word *Homo* means *human being. Habilis* means *handy* or *skillful. H. rudolfensis* had a brain larger than that of *H. habilis.* It also had large molars, like those of the australopithecines. The name *rudolfensis* comes from Lake Rudolph, an old name for Lake Turkana. Fossils of *H. rudolfensis* have been discovered near the lake.

Some anthropologists are uncertain whether *H. habilis* and *H. rudolfensis* were two different species or whether they represent, respectively, the females and males of one species. Such a difference in size between the sexes is known as *sexual dimorphism.* This type of difference appears among many modern apes and was present among the australopithecines. Sexual dimorphism is less extreme in modern human beings.

Another species of early human being, *Homo erectus,* lived at the same time as *H. habilis* and *H. rudolfensis.* The term *erectus* refers to the upright posture of these creatures. Most scientists believe *H. erectus* was the species that evolved into modern people.

Homo erectus had a brain slightly larger than that of *H. rudolfensis,* but it also had smaller back molars. During the course of *H. erectus* evolution, brain size increased, eventually reaching a size just slightly smaller than that of a modern human brain. *Homo erectus* individuals had thick skulls, sloping foreheads, and large, chinless jaws. Their skulls had a *browridge,* a raised strip of bone across the lower forehead. *H. erectus* also had a smaller and less protruding face than *H. habilis* and *H. rudolfensis* had. Fossils indicate that the *Homo erectus* males were larger than the females.

The earliest *Homo erectus* fossils have been found in Africa. They date from more than 1,750,000 years ago. One of the best-known examples of *H. erectus* is a nearly complete fossil skeleton of a boy who was probably about 11 or 12 years old when he died. The skeleton, which is over 1,500,000 years old, was found near Lake Turkana. The boy had already reached 5 feet 3 inches (160 centimeters) in height and might have grown to 6 feet 1 inch (185 centimeters) if he had lived to adulthood.

Members of *H. erectus* eventually migrated from Africa to Asia and Europe. The species reached the is-

land of Java, in Indonesia, by 1,200,000 years ago, and perhaps as early as 1,600,000 years ago. *H. erectus* reached Europe more than 700,000 years ago. By 600,000 years ago, the species had spread into northern Asia.

How they lived. Many anthropologists believe that *H. habilis, H. rudolfensis,* or *H. erectus* made the first stone tools. The earliest tools were sharp-edged stones used for cutting, scraping, and chopping. Prehistoric people made them by striking one stone with another, chipping pieces away to produce a cutting edge. The first tools were crude, but over time early human beings began to craft tools of a finer quality. Later toolmakers used mallets of wood or bone to tap away small chips of stone, producing a straight, sharp cutting edge.

Scientists believe the early human beings ate meat in addition to fruits, insects, and plants. Archaeologists have found animal bones buried with stone tools from the time of the first people. Some of the bones show scratch marks that were probably made by the cutting action of stone tools. These marks indicate that the early butchers used tools to cut up game and to scrape meat off bones. But scientists do not know whether these early people killed large animals themselves or merely ate the meat after the animals had been killed by predators.

During the time of *Homo erectus,* tools became more skillfully made, and new tool types appeared. For example, *H. erectus* made double-edged cutting tools called *hand axes* out of stone. Workers probably held these axes in their hands and used them without a handle for many tasks, such as shaping wood or bone and cutting up meat. *H. erectus* may have hunted large animals.

Homo erectus was probably the first human being to master the use of fire. These people may also have been the first to wear clothing. Scientists believe that as *H. erectus* moved into northern areas and faced cold winters, fire and clothing became necessary. Archaeologists have not found any traces of early clothing, but it was probably made from animal hides. The oldest evidence of the use of fire was found in a cave that *H. erectus* occupied about 600,000 years ago near what is now Beijing, in northern China. Stone tools and the remains of more than 40 *H. erectus* individuals were found in the cave, along with burnt animal bones.

The development of *Homo sapiens*

Scientists classify today's people as *Homo sapiens,* a term that means *wise human being.* Anthropologists disagree about the precise evolutionary relationships between *Homo sapiens* and earlier peoples. They also disagree about where and when *H. sapiens* first appeared.

Compared with the earliest human beings, people today have a high forehead and a higher and more rounded skull. They lack the browridge of earlier people and have a chin and a smaller, less-protruding face.

The origin of *Homo sapiens* is related to the origin of human races. Anthropologists today reject the idea that human beings can be divided into biologically defined races. Only slight differences distinguish the features of any two modern peoples who developed in neighboring regions. Thus, it is hard to draw a dividing line between them. But groups of people who have lived in certain parts of the world for many thousands of years tend to differ in appearance from groups in other parts of the world. These differences are probably adaptations to local environments. For example, people whose ancestors have lived for generations in sunny climates tend to have dark skin. Dark pigment helps protect the skin from sunburn and reduces the risk of skin cancer.

Anthropologists have developed two main theories to explain the origin of modern human beings and the development of what are sometimes called "races"—that is, the physical differences among populations in different regions. These theories may be referred to as (1) the multiple origins theory and (2) the single origin theory.

The multiple origins theory states that after *H. erectus* spread out of Africa, groups of these early human beings settled in different parts of Asia, and then, sometime after 1 million years ago, reached Europe. As they moved to new areas, with differing climates and plants and animals, these scattered populations developed different characteristics. In each geographical area, human groups with different appearances evolved. But because of the constant movement of individuals from one region to another, they continued to form a single species. Most anthropologists who support the multiple origins theory believe that between about 700,000 and 400,000 years ago, these scattered groups of *H. erectus* evolved into *H. sapiens.*

According to these scientists, the first *Homo sapiens* differed greatly from modern people, and in many ways strongly resembled *H. erectus.* The main difference between early *H. sapiens* and *H. erectus* was that early *H. sapiens* had a higher and more rounded skull. But like *Homo erectus,* the first *H. sapiens* individuals had large faces that protruded around the mouth and nose. They also had big browridges and low, sloping foreheads. These people lacked a chin, a feature found only in later *H. sapiens.* The brain size of early *H. sapiens* varied. Some of these people had brains that were similar in size to those of late *H. erectus.* Others had brains as large as modern human brains.

Neanderthals make up one of the groups that supporters of the multiple-origins theory classify as early *H. sapiens.* Neanderthals are the most widely known of the early human beings, mainly because their fossils were the first traces of prehistoric people ever discovered. The term *Neanderthal,* also spelled *Neandertal,* comes from the Neander Valley near Düsseldorf, Germany. The first Neanderthal fossils were found there in 1856.

Neanderthals lived in Europe, and eventually in the Middle East, between 130,000 and 30,000 years ago. They had features typical of early *H. sapiens,* including a protruding face, large browridge, and low forehead. Most Neanderthals also lacked a chin. But on the average, their brain was larger than that of modern human beings. Neanderthals were also large and muscular.

According to the multiple origins theory, today's human beings eventually developed from the Neanderthals and other groups of early *H. sapiens* who lived in different parts of Europe, Africa, and Asia. In time, these groups evolved higher, more rounded skulls. Their large browridges and protruding faces gradually disappeared, and they developed a chin. But they maintained certain differences in appearance that had developed during their long evolution in different regions. These local differences now distinguish different groups of modern peoples around the world.

The best evidence supporting the multiple origins

theory comes from a series of skulls found in Indonesia and Australia. In age, these skulls span a period that began about 1 million years ago and lasted until the appearance of physically modern people about 100,000 years ago. All the skulls show similar features characteristic of that part of the world. The fossils appear to represent a population that continuously evolved and, over time, resulted in modern Southeast Asian peoples.

A few anthropologists who accept the multiple origins theory believe that the earliest human beings, those who lived about 2 million years ago, did not form a separate species, such as *Homo erectus.* Instead, they believe that the earliest people belonged to the same species as modern people, *Homo sapiens.* According to these scientists, the key difference between the first people and their prehuman ancestors was the way they lived and obtained food, including their use of stone tools and their greater reliance on hunting. These anthropologists believe that all human beings, early and late, and including those with browridges, no chins, and small brains, should be called *Homo sapiens.*

The single origin theory, like the multiple origins theory, begins with the spread of *H. erectus* out of Africa—perhaps as early as 1,600,000 years ago—and into Asia and eventually Europe. According to the single origin theory, however, the scattered population groups did not maintain contact from their different continents.

Ofer Bar-Yosef, Harvard University

A Neanderthal grave from Kebara Cave in Israel contains a human skeleton that is about 60,000 years old. Such graves suggest that the Neanderthals were the first to bury their dead.

For this reason, they eventually became separate species in Africa, Asia, and Europe. The Neanderthals were one of these species, *Homo neanderthalensis.*

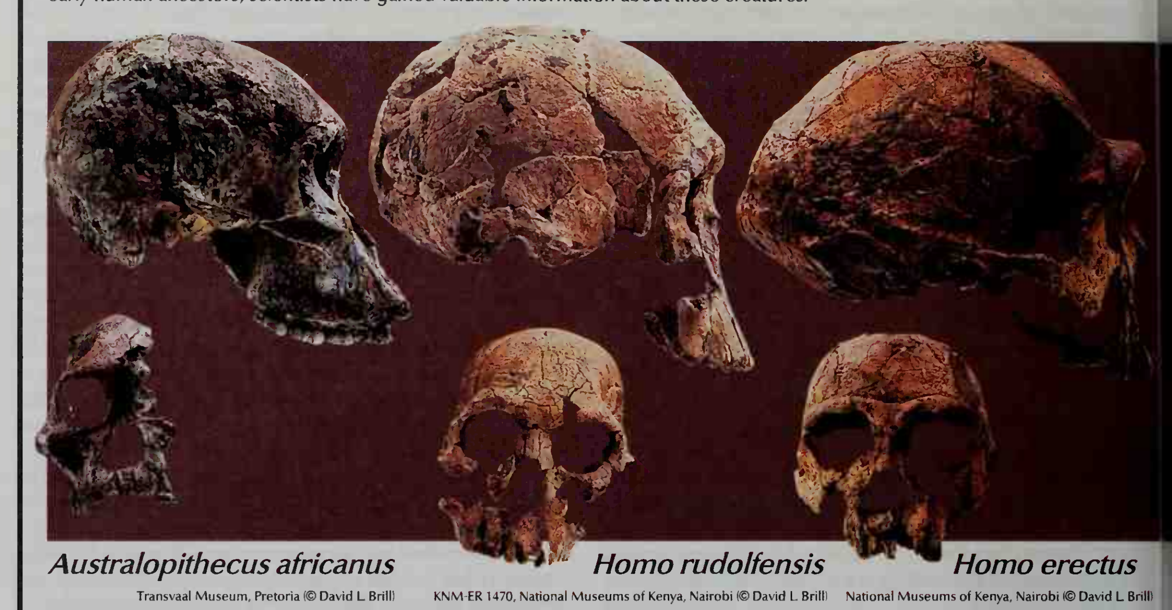
According to the single origin theory, the first *Homo sapiens* appeared in Africa between 200,000 and 100,000 years ago, having developed from earlier human beings in that region. Soon afterward, *H. sapiens* spread to other parts of Africa, as well as to Asia and Europe, replacing the earlier peoples who lived there. All these earlier peoples, such as the Neanderthals, became extinct.

According to the single origin theory, the development of different physical characteristics in today's so-called racial groups began with the spread of *H. sapiens* from Africa between 200,000 and 100,000 years ago. This development would have occurred much later than that portrayed in the multiple origins theory. According to that theory, modern human population differences originated with the first spread of early human beings out of Africa more than 1,500,000 years ago.

Some of the best fossil evidence that supports the single origin theory comes from cave sites in Israel. At two of these sites, called Qafzeh and Skhul, archaeologists excavated fossil skeletons of modern-looking human beings that date from about 100,000 years ago. These people had a chin, a high forehead, and a smaller, less-protruding face than earlier peoples had. They also lacked the large browridge of earlier people and had a higher and more rounded skull. At another site nearby, called Kebara, a Neanderthal skeleton that dated from about 60,000 years ago was found. This fossil evidence shows that Neanderthals lived in the Middle East after the modern type of human beings appeared. Supporters of the single origin theory point out that it is difficult to place the Neanderthals as ancestors of modern human beings if they lived after modern human beings first appeared.

Some scientists also support the single origin theory through use of genetic evidence from living people. Molecular biologists have gained a greater understanding of human evolution by studying the rate of change of human genetic material. By calculating this rate, some scientists have concluded that all living people must have evolved from a small group of human ancestors who lived in Africa about 200,000 years ago. But some molecular biologists doubt that enough is known about human heredity to draw such a conclusion.

Cultural development after *Homo erectus*



The culture of prehistoric people developed extensively after the time of *Homo erectus.* Some of this development occurred during the time of the Neanderthals. But human culture developed more rapidly after the appearance of physically modern people, especially after about 35,000 years ago.

Neanderthals were more skilled hunters and toolmakers than earlier people. The bones of many animals have been found at Neanderthal sites. Some of the bones indicate that these people hunted such large animals as horses, reindeer, and mammoths. But they had more success in capturing hares and other small animals. The Neanderthals made a variety of stone tools and used them to butcher animals, prepare vegetable foods, scrape hides, and carve wood. They also made sharp, pointed tools that may have been spearheads.

Neanderthals lived in Europe during the most recent

The development of prehistoric human beings

The skulls of prehistoric people changed dramatically over time. By studying the fossilized skulls of our prehuman and early human ancestors, scientists have gained valuable information about these creatures.

Prehistoric tools were made chiefly of stone. Neanderthals made a variety of tools, including the hand axe, *top left,* and the scraper, *bottom left.* To form these tools, they used a hard object—such as a rock or bone—to chip pieces away from a carefully selected stone. Later prehistoric people used more complicated toolmaking techniques, such as the one shown on the far left. This process, employed by Upper Paleolithic people, required the cooperation of two individuals. The toolmakers used two hard objects as a hammer and chisel to split bladelike slivers from a large stone. In this way, they could create many useful tools from a single stone.

ice age, when vast sheets of ice covered many northern parts of the world. As a result, they developed qualities that enabled them to cope with harsh winter conditions. Archaeologists have found most evidence of Neanderthals in caves, where many of these people lived to escape the extreme cold. Archaeologists have also discovered sites where Neanderthals camped in the open. These sites provide evidence that the Neanderthals pitched large circular tents around a central hearth area. The tent covering probably consisted of hides, leaves, or bark and was supported by wooden posts.

The Neanderthals were the first people known to have buried their dead. In Neanderthal sites in Europe and the Middle East, archaeologists have uncovered the carefully buried skeletons of women, men, and children.

Physically modern human beings. The cultural activities of the first physically modern people resembled those of the Neanderthals and other early people who lived during that time. For example, the modern-looking human beings from the 100,000-year-old sites of Qafzeh and Skhul were found with the same kinds of stone tools that Neanderthals used nearby. Thus, the appearance of modern human beings did not represent a sudden change in lifestyle or culture from earlier people.

Throughout the early stages of human evolution, the rate of cultural change among prehistoric people was extremely slow. At times, stone tools and other products of human skill remained unchanged for many thousands of years. However, about 35,000 years ago, the rate of cultural change began to accelerate rapidly. This later period is generally referred to as the Upper Paleolithic.

In the Upper Paleolithic, prehistoric people made many advances in their way of life. The best-known type of human beings from this period are the Cro-Magnons. The Cro-Magnons lived in Europe, the Middle East, and North Africa from about 40,000 to 10,000 years ago. Scientists believe they resembled modern Europeans.

The improvement of tools was a major accomplishment of the Cro-Magnons and other Upper Paleolithic people. New tool types and methods of manufacture appeared at a rapid pace. Stone tools made during this time were more refined and complex in design. Toolmakers invented new devices to serve specialized carving, cutting, and drilling functions. Tools of bone, ivory, and animal horns also came into use. Archaeologists have found harpoons, fish spears, and needles made from bone that date from this period. These tools suggest the introduction of such activities as sewing close-fitting clothes and fishing with better equipment.

Upper Paleolithic fossil sites also indicate that these people had become skillful hunters. Some sites hold the remains of thousands of animals. In addition, the bones of mammoths, horses, and reindeer are common, suggesting these people hunted large animals successfully.

The appearance of art was one of the most spectacular developments of the Upper Paleolithic. The oldest known works of art date from this period. Furthermore, the practice of creating art seems to have spread rapidly in Europe, Africa, and Australia.

Some of the oldest artworks from the Upper Paleolithic were ornaments, such as beads made from polished shells. After about 30,000 years ago, prehistoric people began to produce a variety of artwork. They excelled at carving—creating beautiful sculptures of animals and people, usually from ivory or bone. They also made engravings of people, fish, birds, and other animals on bone, ivory, and stone. In addition, the Upper Paleolithic people sculpted clay, ivory, and stone figurines of

Cave paintings were one of the earliest forms of art. Prehistoric people had begun producing them by about 30,000 years ago. Many cave paintings of deer, *left,* were found at Lascaux, a cave in southwestern France. The handprints of prehistoric people, *above,* decorate the walls of Gargas Cave in southern France. These prints show that some of the prehistoric artists had lost parts of their fingers.

women, which may have represented fertility.

A number of caves in Europe are covered with paintings, drawings, and engravings from the Upper Paleolithic. Most distinctive of these are the paintings, which appear on the cave walls and ceilings. Most of the paintings are of the animals early people probably hunted, including bison, mammoths, and horses. Some of the paintings show animals that have been speared.

Many of the paintings are of a high artistic quality. Paleolithic artists used three basic colors: black, red, and yellow. They got these pigments from natural sources, including charcoal, clay, and iron and other minerals.

The development of speech. No one knows when or how spoken language developed. However, many anthropologists think that human beings may have first begun to speak sometime during the Upper Paleolithic. These scientists believe that the many cultural developments that occurred at this time—especially the appearance of art—may be related to the development of speech. The beginnings of speech, the creation of artwork, and the making of complex tools all required advancements in human intelligence and cooperation.

The spread of settlement. Prehistoric people spread into new areas during the Upper Paleolithic period. Cultural and technological advances enabled them to migrate to such places as Australia, the Pacific Islands, and North and South America.

As early as 65,000 years ago, people used boats to reach Australia. About 20,000 years ago, people from Australia and Asia began to colonize the Pacific Islands. These people used sophisticated navigational systems involving knowledge of the stars, water currents, and wind direction. They also used simple navigational tools.

By 130,000 years ago, human beings had spread to the cold, harsh plains of western Siberia, but not until later did people move into the eastern part of the region. At that time, because so much water had been frozen as glacial ice, the level of the oceans and seas was lower than it is today. As a result, the Bering Strait was dry and formed a land bridge between northeast Asia and North America. Most scientists believe prehistoric people crossed this bridge and were living in North America by about 15,000 to 20,000 years ago. Eventually, early modern people populated all of North and South America.

The most recent ice age ended about 11,500 years ago. As the ice receded, the environment of many prehistoric people changed and greatly affected their way of life. In some areas, such as Europe, forests began to spread across the land. The people of these areas learned to hunt new species of animals and gather new varieties of plants from the forests. In other parts of the world, people began to experiment with methods of controlling their supply of food. This led to farming.

The rise of agriculture, according to most scientists, began in the Middle East about 10,000 years ago, or 8000 B.C. The first farmers lived in a region called the Fertile Crescent, which covers what is now Lebanon and parts of Iran, Iraq, Israel, Jordan, Syria, and Turkey. At first, these people probably did not depend entirely on the crops they raised. But as they improved their methods, farming became their most important source of food. The earliest plants grown in the Middle East were probably barley and wheat. Early farmers in the Middle East eventually raised cattle, goats, and sheep.

The first farmers originated in areas where there were enough wild plants and animals to provide food for

Where remains of prehistoric people have been found

The earliest fossils and other remains of prehistoric people have been found in Africa, Asia, and Europe. Most scientists believe that our closest prehuman ancestors originated in Africa, and prehistoric people later spread to other parts of the world.

WORLD BOOK map

Important fossils of prehistoric people and their prehuman ancestors

Fossil	Location	Date found	Discovered or identified by	Importance
		Ardipithecus and Australopithecus		
Ardipithecus ramidus	Aramis, Ethiopia	1994	Tim White (U.S.), Gen Suwa (Japanese), Berhane Asfaw (Ethiopian)	Oldest known hominid, dating from about 4,400,000 years ago
Taung child	Taung, South Africa, near Vryburg	1924	Raymond A. Dart (South African)	First australopithecine discovered
Kromdraai hominid (formerly *Paranthropus robustus*)	Kromdraai, South Africa, in the Sterkfontein Valley	1938	Robert Broom (South African)	First *A. robustus* discovered
OH 5, nicknamed "Zinj" (formerly *Zinjanthropus boisei*)	Olduvai Gorge, Tanzania	1959	Mary D. Leakey (British)	First East African australopithecine found
"Lucy"	Hadar, Awash River Valley, Ethiopia	1974	Donald C. Johanson (U.S.)	One of the most complete australopithecine skeletons
Laetoli fossil footprints	Laetoli, Tanzania, near Lake Eyasi	1978	Mary D. Leakey (British)	Evidence that australopithecines walked erect
Anamensis fossils	Kanapoi, Kenya; Lake Turkana, Kenya	1994	Peter Nzube Mutiwa (Kenyan)	Oldest australopithecine
		Homo habilis and Homo rudolfensis		
Olduvai Gorge *Homo habilis*	Olduvai Gorge, Tanzania	1960	Jonathan Leakey (Kenyan)	First *H. habilis* found
KNM-ER 1470	Lake Turkana (formerly Lake Rudolf), Kenya	1972	Bernard Ngeneo (Kenyan)	Oldest known *H. rudolfensis* skull
		Homo erectus		
Java fossils (formerly *Pithecanthropus erectus*)	Trinil, Indonesia, on the Solo River, island of Java	1891	Eugène F. T. Dubois (Dutch)	First *H. erectus* found
Peking fossils	Zhoukoudian, near Beijing	1921-1937 1949-1966	Davidson Black (Canadian)	Largest collection of *H. erectus fossils* found
East Turkana *Homo erectus*	Lake Turkana, Kenya	1975	Richard E. F. Leakey (Kenyan)	Oldest African *H. erectus* found, about 1,800,000 years old
Nariokotome boy	Lake Turkana, Kenya	1984	Kamoya Kimeu (Kenyan)	Skeleton of a boy, the most complete *H. erectus* found
		Homo sapiens and Neanderthals		
Kabwe fossil (formerly Rhodesian man)	Kabwe (also known as Broken Hill), Zambia	1921	Arthur Smith Woodward (British)	Early African *H. sapiens*
Dali skull	Dali, Shanxi Province, China	1978	Wu Xinzhi (Chinese)	Early Asian *H. sapiens*
Neanderthal	Neander Valley, Germany, near Düsseldorf	1856	Johann K. Fuhlrott (German)	First fossil recognized as remains of prehistoric people
"Old Man" of La Chapelle-aux-Saints	La Chapelle-aux-Saints, France, near Brive	1908	Amédée Bouyssonie and Jean Bouyssonie (French)	Most complete Neanderthal skeleton
Skhul skeletons	Skhul Cave, Mount Carmel, Israel	1931-1932	Theodore D. McCown and Hallam L. Movius (U.S.)	Early modern humans (*H. sapiens sapiens*), dating from 100,000 years ago
Qafzeh skeletons	Qafzeh Cave, near the Sea of Galilee, Israel	1933-1975	René Neuville and Bernard Vandermeersch (French)	Early *H. sapiens sapiens*, dating from 100,000 years ago
Cro-Magnons	Les Eyzies, France, near Brive	1868	Louis Lartet (French)	First Cro-Magnon skeletons discovered

large populations. As a result, people often settled in permanent villages for years at a time. At the end of the Ice Age, the climate became warmer and affected the food supply. New plants, such as grains, replaced older plants. Scientists believe that Upper Paleolithic people could live in permanent settlements because they discovered how to control these new plants and increase the amount of food in their area. They learned that they could plant seeds from the plants they ate. They also learned that they could domesticate animals, perhaps by capturing young ones from the wild and raising them. In time, people began to depend on these planted crops and domestic animals for a steady supply of food.

People were herding cattle and growing grain in northern Africa by 6000 B.C. By about 5000 to 4000 B.C., agriculture had developed independently in Asia. In the Yangtze Valley of China, and perhaps in what is now Thailand, farmers grew rice and millet. By the same time, people had begun to farm in the Indus River Valley of what is now Pakistan.

Between about 4500 and 4000 B.C., farming peoples spread from southeastern Europe into the dense forests of central and western Europe. These people brought wheat and cattle with them. Foraging people in Scandinavia learned how to farm from these newcomers.

Agriculture began to develop in southern Africa by about 3000 B.C. By 1500 B.C., people had begun to cultivate corn and beans in what is now Mexico. By 1000 B.C., peoples in what became the eastern United States were raising gourds and sunflowers. Farming began later in other parts of North America.

Changes in lifestyle. Prehistoric farmers, called *Neolithic* people, had a way of life that differed from that of Upper Paleolithic people. In some ways, farming made life easier. It provided a steady supply of food and enabled people to live in one place for a long time. But farmers had to work more than hunters and gatherers.

Prehistoric farmers set up villages near their fields and lived there as long as their crops grew well. Most fields produced good crops for a few years. The land then became unproductive because the crops used up nutrients in the soil. The farmers did not know about fertilizers. They shifted their crops to new fields until none of the land near their village was fertile. Then they moved to a new area and built another village. In this way, farmers settled many new areas.

Prehistoric farmers built larger, longer-lasting settlements than the camps that Paleolithic people had built. In the Middle East, for example, early farmers constructed their houses of solid, sun-dried mud, sometimes on stone foundations. Dried mud was much more resistant to weather than the materials earlier people used, such as skins and bark. The early farmers also learned to build fences to confine and protect their livestock.

The end of prehistoric times. Neolithic farmers made inventions and discoveries at an even faster rate than did the people of the Upper Paleolithic. Early farmers developed a number of useful tools. These implements included sickles to cut grain, millstones to grind flour, and polished stone axeheads.

Perhaps as early as 9000 B.C. in Japan, and somewhat later in the Middle East, people discovered how to make pottery. Before then, they used animal skins or bark containers to hold water. To boil water, early cooks had to drop hot stones into the water because they could not hang animal skins or bark over a fire. Pottery containers enabled people to hold and boil water easily. Farmers also used pottery to store grain and other food.

No one knows when people made the first objects out of metal. But metals became important only after metalworkers learned to make bronze, a substance hard and durable enough to make lasting tools. People of the Middle East made bronze as early as 3500 B.C. The Bronze Age began when bronze replaced stone as the chief toolmaking material. In some areas, such as the Near East, the Bronze Age began about 3000 B.C.

The development of farming was an important step toward the rise of civilization. As farming methods improved and food became more plentiful, many people were freed from the jobs of food production. These people developed new skills and trades. In addition, the abundant food supply enabled more people to live in each community. In time, some farming villages became cities. The first cities appeared by about 3500 B.C. These cities were the birthplaces of modern civilization.

Archaeologists believe writing was invented about 3500 B.C. in cities in the Tigris-Euphrates Valley in what is now Iraq. People then learned to record their history, and prehistoric times came to an end.

Studying prehistoric people

Since the mid-1800's, scientists have learned much about prehistoric people and their ways of life. They have used various methods to obtain this knowledge.

Studying fossils of prehistoric people has provided anthropologists with much of their most valuable information. Human fossils give direct evidence of what prehistoric people looked like, what they ate, how long they lived, and how their lives differed from ours.

Unfortunately, fossil bones and teeth are scarce because certain unusual conditions must be present for a fossil to form. An animal or person must be buried soon after death, and minerals from the soil must gradually replace the bony material to create a fossil. Also, the bones and teeth that do become fossils have often been broken, damaged, or distorted by the weight of the deposits in which they were buried. Soft tissues—such as skin, hair, and internal organs of prehistoric people—decay without leaving any fossil remains. As a result, scientists cannot determine certain characteristics of early human beings, such as the shape of their nose, the color of their skin, or the texture of their hair.

After a fossil is discovered, scientists first determine whether it came from an adult or a child and whether the individual was a male or a female. Anthropologists then compare the fossil with similar structures from other extinct hominids, living people, and apes. These examinations enable scientists to better understand the specimen's place in human evolution. Later, anthropologists study the fossil to determine a relationship between the individual's physical structure and its way of life. For example, looking at the way the teeth have been worn down often provides clues about the foods the individual ate. The chemicals in fossil bones can also give clues about the diet of extinct hominids.

Examining prehistoric sites is another method anthropologists use to gain information about prehistoric people and their way of life. These sites may be places

where prehistoric people camped, made tools, butchered animals, or buried their dead.

The excavation of prehistoric sites is a complicated process. Archaeologists carefully scrape away soil, sand, or rock to reveal tools, bones, pottery, and other evidence of early human life. They make detailed notes and maps, often using computers to record the exact position of all important items. They later use these records to precisely reconstruct the layout of the site. By studying the objects they find and the layout of the site, scientists learn how prehistoric people used the site and how these activities fit into their way of life.

Today, archaeologists avoid excavating the entire site they are working on. They try to leave enough of the ancient deposit so that future scientists, with more advanced techniques, can return to the site and learn still more about the people who lived there.

Scientists have found much evidence of prehistoric people's lives at sites up to 100,000 years old. These sites have produced ancient tools, pottery, artwork, bits of clothing, traces of dwellings, and evidence of food, such as animal bones and plant material. Sometimes, burial sites are found. These clues enable anthropologists to form a fairly detailed picture of early people's lives. Unfortunately, scientists have found little of this type of evidence at sites older than 100,000 years. As a result, we know much less about hominids who lived before then.

Placing prehistoric people in time is an important element of learning about human ancestors. To understand the significance of a newly discovered hominid fossil, scientists must determine how that hominid relates to others that have already been studied. This relationship can be determined by *dating* the newly found fossil—that is, by determining when it was alive.

Scientists have traditionally dated fossils by studying the deposit in which the fossil was found. Based on knowledge of geological history, scientists can determine the age of the deposit. They then interpret this information to provide an approximate age for the fossil.

Other dating methods are much more accurate. These methods are based on the fact that certain *radioactive isotopes* (unstable forms of chemical elements) decay at a known rate and form different isotopes. By measuring the amount of each isotope in a fossil, scientists can determine how long the decay has been going on and therefore how old the fossil is. The most commonly used dating methods of this type are *radiocarbon dating* and *potassium-argon dating.* Radiocarbon dating is sometimes called *C-14 dating.* Potassium-argon dating is also known as *K/AR dating.* Other methods include *electron spin resonance* and *thermoluminescence,* which involve dating rocks found at archaeological sites.

Analysis of the genetic materials of living people is another recently developed method of studying prehistoric people. This method largely involves the study of the genetic material DNA (deoxyribonucleic acid).

Molecular biologists in this field examine DNA from living people and compare it with DNA from other people and from apes and other living primates. Some scientists have extracted DNA from the bones of prehistoric people, though the process is extremely difficult.

Using genetic samples, scientists study the rate of change that DNA appears to go through during evolution. Scientists often use computers to help analyze data obtained through this research. From these studies, they have gained valuable knowledge about the relationship between living people and their ancestors. In many cases, however, anthropologists have disagreed on how to best interpret the results of these studies. Alan E. Mann

Alan E. Mann, University of Pennsylvania

Anthropologists dig for objects left behind by prehistoric people. The scientists above are digging at St.-Césaire, France, a site occupied by Neanderthals about 35,000 years ago.

Prejudice is an opinion formed without taking the time or care to judge fairly. Such an opinion may be favorable or unfavorable and is held without regard to the available evidence. In this article, *prejudice* refers to an unfavorable opinion held in this way about the members of a particular social group. Prejudiced individuals tend to twist, distort, misinterpret, or even ignore facts that conflict with their predetermined opinions. For example, a prejudiced person might believe that all individuals of a certain age, national origin, ethnic group, religion, sex, or region of the country are lazy, violent, stupid, emotionally unstable, or greedy.

Due to prejudice, people have been denied jobs, housing, education, and participation in government. In Nazi Germany, extreme prejudice led to the killing of millions of Jews and other members of minority groups in the 1930's and during World War II (1939-1945).

A number of elements may contribute to prejudice. These elements include (1) competition, (2) religious ideas, (3) fear of strangers, and (4) extreme nationalism. Prejudice may develop when one group fears that competition from another group will deprive them of prestige, privilege, political power, or economic opportunities. Religious ideas—especially a lack of tolerance for religions other than one's own—have contributed to prejudice against certain races and religious groups. Some people have suggested that prejudice arises from a natural fear of strangers. Extreme nationalism may cause prejudice by encouraging people to regard foreign characteristics as inferior.

Education, certain types of contact between groups, and institutional change may help reduce prejudice. Education helps correct false generalizations that form the basis of prejudice. Contact between groups is most likely to reduce prejudice when the groups work together for a common cause. Changes in institutions, laws, and customs to reduce discrimination might eliminate some prejudice. William Julius Wilson

Premature birth, *PREE muh CHUR,* occurs when a woman gives birth to a baby before the end of the normal period of pregnancy. The normal period of pregnancy ranges from 37 to 41 weeks after a woman begins her last menstrual period prior to becoming pregnant. Births that take place before the end of 37 weeks of pregnancy are said to occur *preterm.*

Most premature infants that weigh more than 3 $\frac{1}{3}$ pounds (1.5 kilograms) at birth grow up as healthy as babies born after a normal pregnancy. Premature babies weighing less than 2 $\frac{1}{5}$ pounds (1 kilogram) at birth have the poorest chance of survival.

In many premature infants, certain organs—especially the lungs—have not developed sufficiently for the baby to survive without medical assistance. *Hyaline membrane disease,* also called *respiratory distress syndrome,* ranks among the most serious lung disorders that strike these babies. Some infants with this condition are attached to a respirator (see **Hyaline membrane disease**). Other common problems include the inability to digest normal-sized feedings and the body's lack of adequate control over its temperature. If the baby can suck and swallow, special formulas may be given by bottle. Some premature infants must be fed by means of a tube passed through the nose and into the stomach. Others may need to be fed entirely through a tube inserted into a blood vessel. Most premature infants are placed in an incubator to assure a constant body temperature.

Premature births occur least often among healthy women who receive periodic medical care. A woman can help assure normal birth by eating a well-balanced diet and by avoiding the use of tobacco, alcohol, and all drugs except those recommended by her doctor. In the United States, about 7 percent of white babies and 14 to 15 percent of nonwhite babies are born prematurely.

The causes of preterm births are poorly understood. Factors involved include conditions in the mother, the baby, and the *placenta.* The placenta is an organ that develops during pregnancy, joining the mother and the unborn baby. Many women have a medical condition associated with premature birth. Such conditions include abnormalities of the uterus, drug addiction, high blood pressure, and being pregnant with more than one baby. A woman who has had a premature baby or a miscarriage has about a 20 percent chance of again giving birth prematurely. Scientists have developed a number of drugs that can help stop preterm labor before it results in premature birth. Lois Kazmier Halstead

Premenstrual syndrome (PMS) is a condition that affects many women 3 to 10 days before the beginning of their menstrual period. The syndrome has a variety of symptoms, including anxiety, depression, sudden mood changes, crying easily, feeling angry or irritable, headaches, swelling, breast soreness, constipation, food cravings, and fatigue. Women affected by PMS may have any number of these symptoms at the same time, and the symptoms may be mild or severe.

The cause of PMS is unknown. Most doctors believe the symptoms result from hormone changes that take place during the menstrual cycle. See **Menstruation.**

Doctors distinguish PMS from other conditions by the time at which it occurs. If the symptoms occur during the few days before the woman's menstrual period

begins and at no other time, the condition is PMS.

Some women can ease symptoms of PMS by exercising regularly and by changing their diet to meet the needs of the body. Many women with severe symptoms need medication for relief. Drugs that prevent the normal hormone changes of the menstrual cycle seem to be the most effective. Mona M. Shangold

Premier. See Prime minister.

Prendergast, *PREHN duhr GAST,* **Maurice Brazil,** *MAW rihs BRAZ uhl* (1859-1924), was an American painter and illustrator. Prendergast's paintings capture the life and movement of crowds in city parks and at the seaside. They show his familiarity with European Postimpressionist handling of form, color, and light.

Oil painting on canvas; the Metropolitan Museum of Art, George A. Hearn Fund, 1950. Photograph © the Metropolitan Museum of Art

A Prendergast painting called *Central Park* was completed about 1910. Its patchy color, thick brushstrokes, and outdoor subject matter are typical of the artist's Postimpressionist style.

Prendergast was born in St. John's, Newfoundland, and grew up in Boston. He was attracted by Robert Henri's philosophy of independent and spontaneous expression in art. In 1908, he exhibited with Henri's group of realistic painters called *The Eight* (later called the *Ashcan School* by critics). In 1913, Prendergast exhibited in the Armory Show of modern art in New York City.

Charles C. Eldredge

See **Ashcan School; Henri, Robert.**

Preposition, in grammar, is a word that introduces a word or phrase and connects that word with the word it modifies. In "The house beside the stream," *beside* is a preposition. It has an object, *stream.* The phrase as a whole acts as an adjective modifying *house.*

There are only about 60 English prepositions. The most common include *at, by, in, for, on, to,* and *with.* Prepositions must have objects, the words or phrases that they introduce. Thus, *down* is a preposition in the sentence "Mary fell *down* the well." In the sentence "Mary fell *down,*" *down* has no object and is an adverb.

Some prepositions express clear meanings, such as time *(before, during, following),* or location *(against, near).* Other prepositions function mainly to express grammatical meanings, as in "The barking *of* the dogs kept me awake." By definition, prepositions are single words, but there are multiword phrases of the form *preposition-noun-preposition.* These phrases function as a unit *(by means of, in addition to, in spite of).*

Prepositions also are used with nouns, adjectives, and verbs in an *idiomatic* sense—that is, the combination of words assumes a special meaning. For example, we may *agree with, agree to, agree on, agree about,* or *agree among.* We may have a preference *for* something, but choose one thing in preference *to* another. We may be doubtful *of* or *about.* A woman may be impatient *with* her secretary or impatient *for* the arrival of a friend. No rules explain the differences in usage.

It used to be said that one should never end a sentence with a preposition. However, this rule is now considered old-fashioned and never really described actual usage. Prepositions ordinarily precede their objects, but that order need not be followed. Most people recognize that "He knew what he came *for*" is a more natural expression than "He knew *for* what he came."

In many of the world's languages, such as Japanese, the equivalent of English prepositions come after their objects. Since these words come after rather than before their object, they are called *post*positions rather than *pre*positions. Susan M. Gass

Pre-Raphaelite Brotherhood, *pree RAF ee uh lyt,* was a group of seven young English artists and writers who wanted to reform England's art. They chose the name in 1848. They called themselves Pre-Raphaelites because they admired the simple, informal style of Italian painting before the work of Raphael in the early 1500's. In 1850, the group published a magazine, *The Germ,* to illustrate and spread their doctrines.

The leading Pre-Raphaelites were William Holman Hunt, Sir John Everett Millais, and Dante Gabriel Rossetti. They were resolved to paint according to nature, not according to rules. This led them to use striking color and minute, abundant detail. The paintings and poems of the group are often heavily symbolic. Many are set in the distant past, and a number of them have religious and literary themes. English critics ridiculed the Pre-Raphaelites at first. The group gained acceptance after receiving the support of English art critic John Ruskin. The Pre-Raphaelite Brotherhood broke up in 1854.

K. K. Collins

Oil on canvas; Manchester City Art Gallery, England

A Pre-Raphaelite painting called *The Hireling Shepherd* was painted in 1851 by William Holman Hunt. The painting shows the detailed realism and rich color typical of the group's style.

Presbyter John. See Prester John.

Presbyterian Church (U.S.A.), *PREHZ buh TIHR ee uhn,* is the largest Presbyterian denomination in the United States. It was formed in 1983 through a union of the United Presbyterian Church in the U.S.A. and the Presbyterian Church in the United States.

The Presbyterian Church (U.S.A.) has about 2,600,000 members. The members belong to congregations governed by a board called a *Session.* The congregations are organized into regional *presbyteries.* The presbyteries elect members to regional governing bodies called *synods.* A General Assembly meets annually to decide matters concerning the church's constitution.

Critically reviewed by the Presbyterian Church (U.S.A.)

Presbyterians, *PREHZ buh TIHR ee uhnz,* form a large group of Protestant denominations in English-speaking countries. Outside these countries, most churches of this tradition are called *Reformed*—for example, the Dutch Reformed Church. About 100 denominations belong to the World Alliance of Reformed Churches.

The term *presbyterian* refers to a distinctive pattern of church government. *Presbyter* is the New Testament term for *elder.* Presbyterian congregations are governed by boards, called *sessions* or *consistories,* composed of the minister and lay elders. The sessions send representatives to church councils, called *presbyteries* or *classes,* which oversee the congregations of the district. The presbyteries are represented in regional *synods* or *assemblies.* Representative government operates at all levels, with lay elders participating equally with ministers. All the ministers have equal rank.

Teaching and worship. The Presbyterian and Reformed tradition has always referred to the Bible as the final religious authority. The churches have produced a series of official statements expressing their understanding of Biblical truth. Of these basic documents of Reformed theology, the two best-loved and most influential are the *Heidelberg Catechism* (1563) and the *Westminster Shorter Catechism* (1647). The earlier catechism is widely used in Europe, and the later one is more popular in English-speaking countries. The American Presbyterian *Confession of 1967* is another official statement.

The most influential theologian in the developing years of the Reformed tradition was John Calvin. He was more a commentator on the Bible than a systematic thinker, and scholars debate whether Calvin's thought can be summed up under any single theme. One central point in Calvin's thinking is the conviction that God is the actual present ruler over all creation. This belief is basic to the Reformed tradition generally.

Predestination is another important theme. It is less central in Calvin but more important in the thought of some later Reformed theologians. Predestination is a doctrine which states that God determines the eternal destiny of humanity. The conception is illustrated by Jesus's saying "You have not chosen me, it is I who have chosen you" (John 15:16). Predestination is no longer a characteristic theme of Reformed teaching.

In worship, the Reformed churches have always stressed preaching, along with the Biblical sacraments of baptism and the Lord's Supper. The Reformed churches have produced many great preachers. Congregational worship was once characterized by the singing of psalms translated into the *vernacular* (local languages) and arranged in meter. Within the last 100 or 200 years, hymns have generally replaced psalms. The formal *liturgies* (church services) during the Reformation of the 1500's were largely replaced by *free prayer* beginning in the 1600's. The Reformed churches have partially returned to set forms of worship.

History. The Reformed tradition has always been the most international of the main Protestant bodies. Unlike Anglicanism and Lutheranism, Reformed churches often had to organize without government support, and sometimes under persecution. Many of their leaders, including Calvin and John Knox, were exiles or refugees from France, England, Scotland, the Netherlands, Germany, Italy, Poland, or Hungary.

Geneva, Switzerland, was a notable international refugee center. From Geneva, Reformed ideas and leaders spread throughout Europe. Reformed churches were organized in nearly all European countries, each with its statement of faith, liturgy, and form of government.

The term *presbyterian* was not generally used for Reformed churches until the English Civil War of the 1640's. During the war, Parliament summoned the Westminster Assembly, a council of clergymen, to advise the government on church affairs. The assembly devised a plan of presbyterian organization for the Churches of England, of Scotland, and of Ireland. It also drafted the Westminster Confession, the Larger and Shorter catechisms, and a worship manual. This program did not survive the restoration of the monarchy in 1660. But the theology of the assembly documents remained influential for Presbyterians, Congregationalists, and most Baptists throughout the English-speaking world.

The Presbyterian and Reformed churches played an important part in the great missionary movement of the 1800's. About half the member churches of the present World Alliance are "younger" churches formed in Asia, Africa, and Latin America. In several cases, the Presbyterian and Reformed churches have played an important role in forming united churches with other denominations. This has been the case in China, Japan, south India, and the Philippines.

In 1983, the northern United Presbyterian Church in the U.S.A. and the southern Presbyterian Church in the United States voted to reunite. They formed the Presbyterian Church (U.S.A.). The nation's second largest Presbyterian church is the Presbyterian Church in America, with over 200,000 members. It was formed in 1973 and has headquarters in Atlanta, Georgia.

Prescott, Samuel (1751-1777?), was an American physician and patriot who completed Paul Revere's ride warning the colonists that the British were coming. At the start of the Revolutionary War in America, the British planned to destroy American military supplies stored in and near Concord, Massachusetts. Revere and William Dawes, another patriot, left Boston on April 18, 1775, to

warn the colonists. Prescott joined Revere and Dawes as they left Lexington shortly after 1 a.m. The three men continued toward Lexington until the British captured them. Prescott escaped and reached Concord. His warning enabled the patriots to hide some of the military supplies before the main British forces arrived.

Prescott was born in Concord. He became an army surgeon during the Revolutionary War. He was on a ship authorized to seize British merchant vessels when the British captured him at sea. Prescott died in a British prison in Halifax, Nova Scotia. James Kirby Martin

Prescott, William (1726-1795), was an American colonel during the Revolutionary War in America (1775-1783). He built the fortifications on Breed's Hill and led the militia in the Battle of Bunker Hill. It was once believed that Prescott said to his troops, "Don't fire until you see the whites of their eyes." But historians now question whether he gave this order.

Prescott was born in Groton, Massachusetts. He also fought in King George's War (1744-1748) and in the French and Indian War (1754-1763). Paul David Nelson

President is a title used by many heads of state and leaders of national governments. The term is also used to refer to the head of a corporation, college, institution, social club, or other organization. This article deals with presidents as national leaders.

Nearly three-fourths of the independent countries in the world have presidents as their heads of state. This number includes countries that have military dictators who take the title president.

More than four-fifths of the world's presidents are powerful leaders called *executive presidents.* They make many of the decisions and direct the actions of the government. Such presidents have the power to appoint many high government officials and, in many countries, may veto laws passed by the legislature. The rest of the world's presidents have a largely ceremonial role. These *nonexecutive presidents* act as official representatives of the country and carry out ceremonial duties.

A presidential system of government usually consists of separate *legislative* (lawmaking), *executive* (administrative), and *judicial* (court) branches. A president heads the executive branch. The president is normally elected directly by the people or, in some cases, by the legislature, to a fixed term of office. In theory, the president's powers and duties are described in a country's constitution. In practice, these powers are usually determined by political rather than legal or constitutional issues.

Types of presidential government

There are three types of executive presidency: (1) *limited,* (2) *dual,* and (3) *unlimited.* The main difference between the three types is the extent of the president's authority in relation to other members or sections of the country's government.

Limited presidency exists when a president is freely elected by the people for a specified term of office. A limited presidency is usually found in democratic countries where there is a well-developed multiparty system. Most countries with executive presidents have a limited presidential system. For example, the United States has a limited presidential government.

In a limited presidency, governing powers are divided among the president and other political institutions, such as a parliament or court system. The presidency and other sections of the executive branch operate within the framework of a constitution or legal code. In the United States, for example, the president's power is limited by the power of Congress to pass laws and pay the expenses of government. The Supreme Court of the United States, in its role as guardian of the U.S. Constitution, is another check on the president's power.

The United States style of presidential government provides a model for such Latin American states as Argentina, Brazil, Mexico, and Venezuela, and also for the Philippines. In nearly half of the countries with a limited presidential form of government, the United States model has been altered by the fact that the president appoints a prime minister to head his or her *cabinet* (group of advisers). In such cases, the president retains overall authority but concentrates on defense, foreign affairs, and long-term policy planning. The prime minister handles day-to-day administration and domestic affairs.

Dual presidency. A dual presidential form of government combines elements of both a presidential and a parliamentary system. A president and a prime minister share executive power. The president is generally elected by the people, and the prime minister is chosen from the party or *coalition* (group) of parties that has the support of a majority of the members of the legislature. For example, France has a dual presidency.

In France's dual presidential system, the president is elected for a renewable term of seven years and has considerable formal powers. For example, the president is the head of state and commander-in-chief of the armed forces, has the right to dissolve the National Assembly (France's parliament) once a year, and appoints the prime minister. The president also may preside over Cabinet and Defense Council meetings and call for a national vote on key issues, usually concerning the constitution. The appointed prime minister, who must have majority support within the National Assembly, has control over France's domestic activities.

France provides a model for dual presidential systems in Bulgaria, Finland, Lebanon, Poland, Portugal, and Turkey. When parliamentary and presidential elections take place at the same time, the president and prime minister usually belong to the same party. But if presidential and parliamentary elections occur at different times, the two leaders may belong to different parties and hold conflicting political views.

Unlimited presidency. Unlimited presidential government exists when a country has a chief executive whose authority is not subject to the checks and balances provided by a parliament or judicial system. Unlimited presidential government is usually found in *authoritarian countries,* one-party states run by a strong leader. Legislatures, where they exist, have little power and simply endorse the president's decisions. Several unlimited presidents have reached their positions by using the military to take control of the country by force. The majority of countries with unlimited presidents are in Africa and the Middle East. Thomas E. Cronin

President of the United States

The White House

The seal of the president of the United States includes an eagle holding arrows and an olive branch. The branch symbolizes the desire for peace, and the arrows represent the ability to wage war. The 50 stars stand for the 50 U.S. states.

President of the United States is often considered the most powerful elected official in the world. The president leads a nation of great wealth and military strength. Presidents have often provided decisive leadership in times of crisis, and they have shaped many important events in history.

The Constitution of the United States gives the president enormous power. However, it also limits that power. The authors of the Constitution wanted a strong leader as president, but they did not want an all-powerful king. As a result, they divided the powers of the United States government among three branches—executive, legislative, and judicial. The president, who is often called the *chief executive,* heads the executive branch. Congress represents the legislative branch. The Supreme Court of the United States and other federal courts make up the judicial branch. Congress and the Supreme Court may prevent or end any presidential action that exceeds the limits of the president's powers and trespasses on their authority.

The president has many roles and performs many duties. As chief executive, the president makes sure that federal laws are enforced. As commander in chief of the nation's armed forces, the president is responsible for national defense. As foreign policy director, the president determines United States relations with other nations. As legislative leader, the president recommends laws and works to win their passage. As head of a political party, the president helps mold the party's positions on national and foreign issues. As popular leader, the president tries to inspire the people of the United States to work together to meet the nation's goals. Finally, as chief of state, the president performs a variety of ceremonial duties.

A number of presidents became great leaders. The most admired ones include George Washington, Thomas Jefferson, Andrew Jackson, Abraham Lincoln, Theodore Roosevelt, Woodrow Wilson, Franklin D. Roosevelt, and John F. Kennedy. These leaders served as president when the United States faced extraordinary challenges. They also met those challenges with courage, determination, energy, imagination, and political know-how. Some of the most admired presidents at times ignored the U.S. Constitution or showed little regard for Congress. Nevertheless, their actions won public support. Therefore, like other great presidents, they broadened respect for the presidency and strengthened the office.

The presidency

Legal qualifications. The Constitution establishes only three qualifications for a president. A president must (1) be at least 35 years old, (2) have lived in the United States at least 14 years, and (3) be a natural-born citizen.

Courts have never decided whether a person born abroad to American parents could serve as president of the United States. However, many scholars believe that such a person would be considered a natural-born citizen.

Term of office. The president is elected to a four-year term. The 22nd Amendment to the Constitution

Facts in brief about the president

Qualifications: The United States Constitution provides that a candidate for the presidency must be a "natural-born" United States citizen. The candidate must also be at least 35 years old and must have lived in the United States for at least 14 years. No law or court decision has yet defined the exact meaning of *natural-born.* Authorities assume the term applies to citizens born in the United States and its territories. But they are not sure if it also includes children born to United States citizens in other countries.

How nominated: By a national political party convention.

How elected: By a majority vote of the Electoral College, held in December following the general election on the first Tuesday after the first Monday in November of every fourth year.

Inauguration: Held at noon on January 20 after election. If January 20 is a Sunday, the ceremony may be held privately that day and again in public on January 21.

Term: The president is elected to a four-year term. A president may not be elected more than twice.

Income: The president receives a yearly salary of $400,000. In addition, the president receives a $50,000 annual allowance for expenses, and additional allowances for travel, staff support, and White House maintenance.

Succession: If a president dies, resigns, is disabled, or is removed from office, the vice president assumes the office.

Roads to the White House

WORLD BOOK illustration by David Cunningham

Presidential election | Selection by Congress | Presidential succession

Presidential election

The chief road to the White House is the presidential election, which is held every four years. Political parties nominate their candidates for President and Vice President at national conventions. The nation's voters cast their ballots on Election Day to determine the presidential electors. The Electoral College, made up of the electors chosen by all the states and the District of Columbia, officially elects the President and Vice President.

Selection by Congress

If the Electoral College fails to give any candidate a majority, one of three procedures may be used. (1) The House of Representatives chooses the President from among the top three candidates. Each state's House delegation has only one vote, and the winner must receive a majority of the votes that are cast. (2) If the House fails to choose a President, the Vice President, chosen by the Electoral College or the Senate, becomes President. (3) If both houses fail to choose a President or Vice President, Congress shall by law deal with the situation. Congress would probably apply the terms of the Presidential Succession Act in that case. The Speaker of the House would then become President.

Presidential succession

If the President dies, resigns, or is removed from office, the Vice President becomes President. If the President becomes unable to perform the duties of office, the Vice President serves as acting President during the President's disability. Next in line to the presidency after the Vice President are the following government officials:

1. Speaker of the House
2. President *pro tempore* of the Senate
3. Secretary of state
4. Secretary of the treasury
5. Secretary of defense
6. Attorney general
7. Secretary of the interior
8. Secretary of agriculture
9. Secretary of commerce
10. Secretary of labor
11. Secretary of health and human services
12. Secretary of housing and urban development
13. Secretary of transportation
14. Secretary of energy
15. Secretary of education
16. Secretary of veterans affairs

provides that no one may be elected President more than twice. Nobody who has served as President for more than two years of someone else's term may be elected more than once.

Before the 22nd Amendment was approved in 1951, a President could serve an unlimited number of terms. Franklin D. Roosevelt held office longest. He was elected four times and served from March 1933 until his death in April 1945. President William H. Harrison served the shortest time in office. He died a month after his inauguration in 1841.

The Constitution allows Congress to remove a President from office. The President first must be *impeached* (charged with wrongdoing) by a majority vote of the House of Representatives. Then, the Senate, with the chief justice of the United States serving as presiding officer, tries the President on the charges. Removal from office requires conviction by a two-thirds vote of the Senate.

Only two Presidents, Andrew Johnson and Bill Clinton, have been impeached. Both remained in office, however, because the Senate failed to convict either man of the charges.

Salary and other allowances. Effective Jan. 20, 2001, the President receives a salary of $400,000 a year. The chief executive also gets $50,000 annually for expenses, plus allowances for staff, travel, and maintenance of the White House. Congress establishes all these amounts.

After leaving office, a President qualifies for a basic pension. In the early 2000's, the basic amount for a newly retiring President was $157,000 yearly. But a number of factors may affect the actual size of the pension. For example, it will be larger if the President has served in Congress. Other retirement benefits include allowances for office space, staff, and mailing expenses. Widowed spouses of former Presidents get an annual pension of $20,000.

Roads to the White House

The chief road to the White House is the presidential election held every four years. However, a person may become President of the United States several other ways as well.

The presidential election. Certain people frequently become leading candidates for the presidency because of their experience. They include the Vice President of the United States and governors of such large states as California and New York. A number of Vice Presidents and governors have become President.

Most top presidential candidates must first compete against fellow political party members to win the party's presidential nomination. The Democratic and Republican parties are the two main political parties in the United States. Each holds a national convention to nominate its presidential candidate. The conventions take place a few months before the presidential election.

The Democratic and Republican conventions are lively spectacles. Millions of Americans watch them on television. Delegates wave banners and cheer wildly to support their choice for President. See **Political convention**.

After the conventions, the presidential nominees campaign across the nation. Candidates for President face a number of challenges. They must raise millions of dollars for campaign expenses, attract many volunteers,

Wide World

The inauguration is held on January 20 after the election. This picture shows Chief Justice Earl Warren administering the presidential oath to John F. Kennedy in 1961. Looking on were departing President Dwight D. Eisenhower, *far left,* and future Presidents Lyndon B. Johnson, *second from right,* and Richard M. Nixon, *far right.*

and gain the support of voters throughout the country. The campaign continues until Election Day, the first Tuesday after the first Monday in November.

On Election Day, voters in each state and the District of Columbia mark a ballot for President and Vice President. This balloting is called the *popular vote.* The popular vote does not directly decide the winner of the election. Instead, it determines the delegates who will represent each state and the District of Columbia in the Electoral College. These delegates officially elect the President and Vice President.

The Electoral College has 538 delegates, each of whom casts one electoral vote. To be elected President, a candidate must win a majority, or 270, of the electoral votes. Each state has as many electoral votes as the total of its representatives and senators in Congress. The District of Columbia has three electoral votes.

The Electoral College voting takes place in the December following the presidential election. The results are announced in January. But the public usually finds out who the President will be a few hours after polls close on Election Day. This is because the candidate who gets the most popular votes in a state will receive by custom or law all the state's electoral votes. Thus, the press can forecast the winner.

The winner of the nationwide popular vote nearly always receives a majority of the electoral votes and becomes President. But the Electoral College has elected Presidents who lost the popular vote. These Presidents were Rutherford B. Hayes in 1876, Benjamin Harrison in 1888, and George W. Bush in 2000. A fourth President, John Quincy Adams, also lost the popular vote. But Adams was elected President by the House of Representatives after no candidate had received a majority of the electoral votes in the election of 1824. Ronald Reagan received the greatest number of electoral votes of any President—525 in 1984. See **Electoral College**.

The inauguration is the ceremony of installing the new or reelected President in office. It is held at noon on January 20 after the election. Up to 100,000 spectators attend the inauguration, which usually takes place outside the U.S. Capitol in Washington, D.C. Millions of other Americans see the event on television.

The highlight occurs when the new President takes the oath of office from the chief justice of the United States. With right hand raised and left hand on an open Bible, the new President says: "I do solemnly swear (or affirm) that I will faithfully execute the office of President of the United States, and will to the best of my ability, preserve, protect and defend the Constitution of the United States."

Other roads to the White House. A person may become President in other ways besides winning the presidential election. These procedures are established by Article II of the Constitution; the 12th and 20th amendments; and the Presidential Succession Act.

Article II provides that the Vice President becomes President whenever the President dies, resigns, is removed from office, or cannot fulfill the duties of the presidency. Nine Vice Presidents became President by filling a vacancy. One of them, Gerald R. Ford, followed an unusual route to the White House. President Richard M. Nixon nominated him to succeed Spiro T. Agnew, who had resigned as Vice President in 1973. In 1974, Nixon resigned as President, and Ford succeeded him. Ford was the only President who was not elected to either the vice presidency or the presidency.

The 12th Amendment permits Congress to act if no candidate for President wins a majority of the electoral votes. Then, the House of Representatives chooses the President. Each state delegation casts one vote. The House has elected two Presidents, Thomas Jefferson in 1801 and John Quincy Adams in 1825.

Office of the Curator, The White House

In the Cabinet Room of the White House, the President meets with the Cabinet and the National Security Council.

The 20th Amendment allows leaders of the party of the popular-vote winner to select a new presidential candidate if the winner dies before the Electoral College meets. The college would then vote on that selection. If the popular-vote winner dies after the college meets but before the inauguration, the winning candidate for Vice President becomes President. Neither of these provisions has ever been applied.

The Presidential Succession Act permits other high government officials to become President if vacancies exist in both the presidency and the vice presidency. Next in line is the speaker of the House. Then comes the *president pro tempore* (temporary president) of the Senate, usually the majority party member who has served the longest in the Senate. Next are members of the presidential advisory group known as the Cabinet, with the secretary of state first. The Succession Act has never been applied. See **Presidential succession**.

The executive branch

The President heads the executive branch of the federal government. This branch consists of the Executive Office of the President, 14 executive departments, and about 80 independent agencies.

The Executive Office of the President consists of a number of agencies that work directly for the chief executive. One of them, the White House Office, includes the President's physician, secretaries, and a number of close, influential aides known as *presidential assistants*. See **Presidential assistant**.

The other Executive Office agencies also provide ideas and suggestions concerning many national and international issues. These agencies include the Council of Economic Advisers, Council on Environmental Quality, National Security Council, Office of Administration, Office of Management and Budget, Office of National Drug Control Policy, Office of Policy Development, Office of Science and Technology Policy, and Office of the United States Trade Representative. Franklin D. Roosevelt created the Executive Office in 1939.

The executive departments directly administer the federal government. They are the departments of (1) State, (2) the Treasury, (3) Defense, (4) Justice, (5) the Interior, (6) Agriculture, (7) Commerce, (8) Labor, (9) Health and Human Services, (10) Housing and Urban Development, (11) Transportation, (12) Energy, (13) Education, and (14) Veterans Affairs. In 2002, President George W. Bush proposed the creation of a 15th executive department, the Department of Homeland Security.

The heads of all but one of the executive departments are called *secretaries*. The head of the Justice Department is the *attorney general*. The department heads belong to the President's Cabinet (see **Cabinet**). The President nominates the department heads. All the appointments require approval of the Senate.

The independent agencies administer federal programs in many fields. These fields include aeronautics and space, banking, communications, farm credit, labor relations, nuclear energy, securities, small business, social security, and trade.

Independent agencies may issue rules, enforce penalties, and administer programs that have far-reaching effects on American life. Some independent agencies are known as *regulatory agencies*. Important regulatory agencies include the Federal Reserve System, the Federal Communications Commission, and the Equal Employment Opportunity Commission. The President picks the heads of nearly all the independent agencies. These people require the consent of the Senate.

Roles of the President

The only roles that the Constitution clearly assigns to the President are those of chief administrator of the nation and commander of its armed forces. But court decisions, customs, laws, and other developments have greatly expanded the President's responsibilities and powers. Today, the President has seven basic roles: (1) chief executive, (2) commander in chief, (3) foreign policy director, (4) legislative leader, (5) party head, (6) popular leader, and (7) chief of state.

Chief executive. As chief executive, the President has four main duties. They are (1) to enforce federal laws, treaties, and federal court rulings; (2) to develop federal policies; (3) to prepare the national budget; and (4) to appoint federal officials.

The President uses a variety of powers to carry out administrative duties. Federal laws give the President *emergency powers*—that is, special authority to prevent or end a national emergency. For example, the Taft-Hartley Act allows the President to delay a labor strike for 80 days if it might endanger "national health or safety." The President also may issue *executive orders*—that is, directions, proclamations, or other statements that have the force of laws. They require no action by Congress. One of the most famous executive orders was the Emancipation Proclamation issued by Abraham Lincoln in 1863, during the American Civil War. It declared freedom for all slaves in areas under Confederate control.

The Office of Management and Budget, part of the Executive Office, helps the President plan the federal budget. Presidents often use their budgets to shape key programs. Lyndon B. Johnson did so in the mid-1960's to develop his War on Poverty program.

The President nominates Cabinet members, Supreme

Library of Congress

Abraham Lincoln quickly built up the Union Army after the Civil War began in 1861. After the Battle of Antietam in 1862, he visited General George B. McClellan on the battlefield, *shown here.*

Court justices, and other high federal officials. All such top appointments require Senate approval. The President can appoint a number of personal aides and advisers and can fill hundreds of lower jobs in the executive branch without Senate approval.

The Constitution also allows the President to issue *reprieves* and *pardons* for crimes against the United States, except in impeachment cases. A reprieve delays the penalty for a crime. A pardon frees the offender from a sentence or the possibility of a sentence.

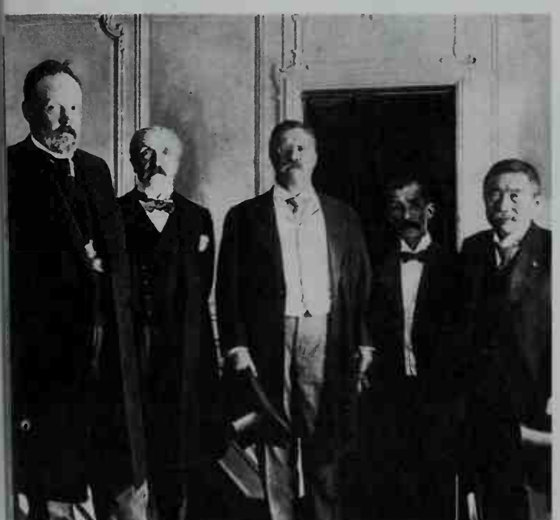
Commander in chief. The President's main duties as commander of the nation's armed services are to defend the country during wartime and to keep it strong during peacetime. The chief executive appoints all the nation's highest military officers and helps determine the size of the armed forces. Only the President can decide whether to use nuclear weapons.

The President shares some military powers with Congress. Top appointments in the armed services require congressional approval. Major military expenses and plans to expand the armed forces also need the consent of Congress. Only Congress can declare war. But Presidents have sent American troops into conflicts that were equal to war though none was declared. In 1950, for example, Harry S. Truman ordered U.S. troops to fight in South Korea. The Korean War (1950-1953) was officially only a "police action."

Congress generally allows the President to exercise broad powers in wartime. During World War II (1939-1945), Franklin D. Roosevelt created many emergency agencies, took control of American manufacturing plants, and even imprisoned American citizens of Japanese descent.

Foreign policy director. The Constitution gives the President power to appoint ambassadors, make treaties, and receive foreign diplomats. The chief executive may refuse to recognize a newly formed foreign government. The President also proposes legislation dealing with foreign aid and other international activities.

Treaties and ambassadorial appointments require approval of the Senate. The President may also make *executive agreements* with foreign leaders. These agreements resemble treaties but do not need Senate approval.



Many Presidents have allowed their secretaries of state to direct U.S. foreign policy. But Woodrow Wilson, Franklin D. Roosevelt, and others have mainly relied on their own judgment in this area.

Some Presidents have helped settle disputes between foreign nations. Theodore Roosevelt and Wilson were among the first Presidents to serve as peacemakers in foreign conflicts. Roosevelt won the Nobel Peace Prize for helping end the Russo-Japanese War (1904-1905). Wilson helped work out the peace treaty that ended World War I (1914-1918).

Legislative leader. The President greatly influences the development of many laws passed by Congress. At the beginning of each session of Congress, the chief executive delivers a State of the Union address to the lawmakers. In this message, the President discusses the major problems facing the nation and recommends a legislative program to solve them. The President also gives Congress detailed plans for new legislation at other times during the year.

Cabinet officers and other presidential aides work to win congressional support for the President's programs. However, the President also may become involved in a struggle over a key bill. In such cases, the President may speak to members of Congress several times to win their backing. This activity requires shrewd bargaining and in many cases fails in spite of the President's influence.

The Constitution allows the President to veto any bill passed by Congress. If both the House and the Senate repass the vetoed bill by a two-thirds majority, the bill becomes law despite the President's disapproval. But Congress has overturned only about 4 percent of all vetoes.

Wide World

heodore Roosevelt met with Russian and Japanese delegates 1905 and helped end the Russo-Japanese War. In 1906, he beıme the first American to win the Nobel Peace Prize.

United Press Int.

Franklin D. Roosevelt explained his policies in informal radio reports that became known as "fireside chats," *shown here.* In 1939, he became the first President to appear on television.

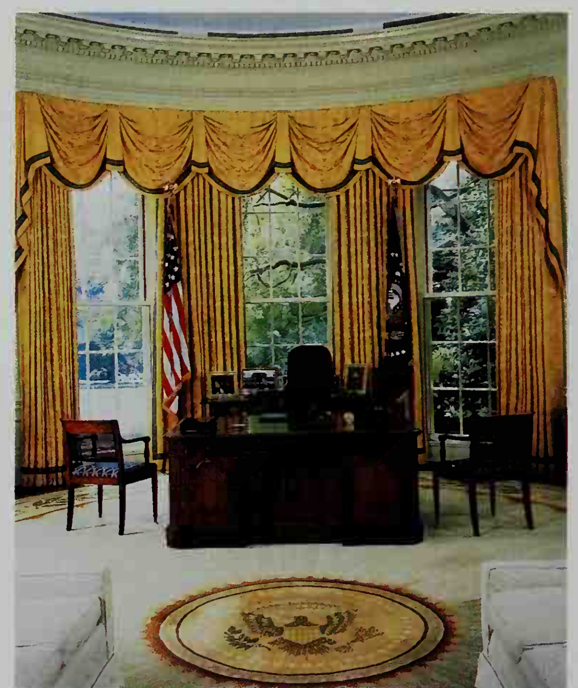
Party head. As leader of a political party, the President helps form the party's positions on all important issues. The President hopes these positions will help elect enough party members to Congress to give the party a majority in both the House and the Senate. Such a strong party makes it easier to pass the President's legislative program.

However, Presidents cannot always control members of their party in Congress. Senators and representatives owe their chief loyalty to the people in their state and local district. They may vote against a bill favored by the President if it meets with opposition at home.

Presidents try to win the support of legislators in several ways. They often use *patronage power,* the authority to make appointments to government jobs. For example, a President can reward a loyal supporter by approving that person's choice for a federal judge. A President also may campaign for the reelection of a faithful party member or promise to approve a federal project that will benefit a legislator's home district.

Popular leader. The President and the American people have a special relationship. The people rely on the chief executive to serve the interests of the entire nation ahead of those of any state or citizen. In turn, the President depends on public support to help push programs through Congress. The President seeks such support by explaining the issues and by showing the confidence and determination to deal with problems.

The President uses many methods to communicate with the public and provide strong national leadership. Woodrow Wilson pioneered the use of regular presidential press conferences to mold public opinion and to rally support. Franklin D. Roosevelt addressed the nation over radio in his "fireside chats." He was also the first President to speak on television. Since the 1960's, Presidents have favored the use of televised addresses from the White House to reach large audiences.



Dwight D. Eisenhower Library

Dwight D. Eisenhower performed a traditional activity as the nation's chief of state when he threw out the first ball to open the 1953 baseball season in Washington, D.C.

Chief of state. As the foremost representative of the U.S. government, the President is expected to show pride in American achievements and traditions. In this role, the President attends historical celebrations, dedicates new buildings and national parks, and may throw out the first ball of the professional baseball season. The President also presents awards to war heroes and invites distinguished Americans to the White House.

In addition, the chief executive greets visiting foreign officials and often hosts formal White House dinners for them. The President also represents the United States in visits to other countries.

© White House Collection from The White House Historical Association

The President's office, an oval-shaped room called the Oval Office, is in the west wing of the White House. The President meets here with many government officials and receives frequent briefings on national and world affairs.

The life of the President

The President is almost always busy. During a typical day, the chief executive attends several meetings and social affairs and may meet 100 or more people. The President works and lives in the White House in Washington, D.C., but makes many outside appearances and spends much time traveling.

The White House. The President's headquarters is the Oval Office, an oval-shaped room in the White House. There, the chief executive meets congressional leaders, foreign officials, and representatives of various groups. The President also spends much time in the Oval Office studying reports from aides and agencies.

The presidential family's main living quarters are on the second floor of the White House. The family also can relax in the mansion's swimming pool and at its bowling lanes and motion-picture theater. The White House grounds have some beautiful gardens.

In spite of its beauty and comfort, however, the White House lacks privacy. Every week, thousands of visitors tour the rooms that are open to the public. Partly as a result, most Presidents enjoy recreation outside the White House.

Nixon Project, National Archives

Camp David is the official retreat of the President of the United States. It lies in a wooded mountain area in Maryland.

Recreation. The President often spends weekends at Camp David, a retreat in the Maryland mountains that is reserved for the nation's leader. Through the years, Presidents have favored various ways to relax. Theodore Roosevelt boxed, hiked, and hunted big game. Warren G. Harding played poker, and Dwight D. Eisenhower played golf. Lyndon B. Johnson and Ronald Reagan enjoyed horseback riding.

The President's family generally attracts wide interest. The wedding of a President's child is a major news event. An interesting relative also draws much attention. Even unimportant activities of members of the President's family sometimes appear in the newspapers.

© Mark Wilson, Getty Images

The president hosts various social functions. This picture shows President George W. Bush, *right,* and Mexican President Vicente Fox Quesada with their wives at a White House dinner.

Some Presidents have had children who helped make the White House cheerful and lively. John Tyler had 15 children, more than any other President. Daughters of seven Presidents were married in the White House. Grover Cleveland was the only President who had a child born in the White House.

Guarding the President. The United States Secret Service guards the President at all times. In addition, agents of the Secret Service continually check the President's food, surroundings, and travel arrangements.

At various times, the President travels in an official car, a private airplane, or a U.S. Navy ship. The chief executive usually flies long distances in a reserved jet called *Air Force One.*

Even though U.S. Presidents get tight protection, four have been assassinated while in office. They were Abraham Lincoln in 1865, James Garfield in 1881, William McKinley in 1901, and John F. Kennedy in 1963. Others have survived attempted assassinations, including Harry S. Truman, Gerald R. Ford, and Ronald Reagan.

A day in the life of the President. The President might begin a typical day by reading a few newspapers. A breakfast conference might follow with such top aides as the press secretary and the White House chief of staff. In the Oval Office, the President signs documents and reads letters, reports, and proposed legislation. Later in the morning, the President might discuss plans with congressional leaders or meet with the Vice President. In the afternoon, the President might see people from various organizations. The President also might take part in a bill-signing ceremony, officially signing into law an act passed by Congress.

In the evening, the President sometimes attends a social function. The White House might host a formal dinner for a foreign official. While dining, the leaders might discuss trade problems, environmental protection, or other issues. The President might spend the late evening reading, perhaps a speech scheduled for the next day or a report on a new foreign aid program.

Development of the presidency

The founding of the presidency. During and immediately after the Revolutionary War in America (1775-1783), the U.S. government operated under laws called the Articles of Confederation. The Articles gave the national government little authority over the states. Most Americans agreed that the nation needed to strengthen its federal government. In 1787, a group of state leaders gathered in Philadelphia to revise the Articles of Confederation. Instead, they wrote an entirely new document—the Constitution of the United States.

Under the Articles, the chief officer presiding over Congress had been called the President, and that title was chosen for the leader of the new government. The Constitution's authors described the presidency in fairly general language because they knew the nation's respected wartime leader, George Washington, would be the first President. They expected Washington to shape the responsibilities of the office for future Presidents.

Washington brought extraordinary courage, prestige, and wisdom to the U.S. presidency. In 1793, he kept the young nation out of a war between Britain and France. In 1794, Washington used federal troops to end the

Whiskey Rebellion, a tax protest in the state of Pennsylvania. This action helped establish the federal government's authority to enforce federal laws in the states.

Strengthening the office. During the early and mid-1800's, the nation had several bold and imaginative Presidents. They interpreted the Constitution in new ways and greatly increased the power of the presidency. One of these leaders was Thomas Jefferson, the third President. Many scholars consider Jefferson the most brilliant person ever to have served in the White House.

Jefferson raised a constitutional question when he approved a treaty to buy the Louisiana Territory from France in 1803. The purchase almost doubled what was then the area of the United States. The Constitution did not specifically give the President power to buy new territory. But Jefferson decided that the purchase was constitutional under his treaty-making power.

Andrew Jackson strengthened the President's role as the nation's popular leader. In July 1832, Jackson vetoed a bill to renew the charter of the Second Bank of the United States. Jackson and many other Americans viewed the bank as a dangerous monopoly and criticized its failure to establish a reliable currency. Later in 1832, South Carolina declared federal tariff laws unconstitutional and refused to collect tariffs at its ports. Jackson declared that no state could cancel a federal law. The President received congressional approval to use federal troops in order to collect the tariffs. Jackson's actions helped force South Carolina to end its rebellion.

The Civil War began in 1861, when Southern forces attacked Fort Sumter. Abraham Lincoln ordered a military draft, blockaded Southern ports, and spent funds without congressional approval. He knew he had used powers the Constitution reserved for Congress. But he believed his actions were needed to save the Union.

The decline of the presidency. After the Civil War ended in 1865, Congress moved quickly to increase its influence in the government. A power struggle broke out between Congress and Andrew Johnson. This struggle led to Johnson's impeachment by the House of Representatives. The prestige of the presidency was damaged, but it was saved from total destruction because the Senate failed, by one vote, to convict Johnson.

Few strong Presidents emerged during the late 1800's. Most Presidents of the period accepted the view that Congress, not the chief executive, had the responsibility to set the nation's basic policies.

The rebirth of presidential leadership. The United States became a world power during the late 1800's and early 1900's. This development helped bring increased power to the President. In the Spanish-American War (1898), the United States took control of Guam, the

Interesting facts about Presidents

Who was the only President who did not win election to either the office of Vice President or President? Ford.
Who was the only President who had served as Speaker of the House? Polk.
Who was the only President to serve two nonconsecutive terms? Cleveland.
Who held the first regular presidential press conferences? Wilson.
Which President was sworn into office on an airplane? Lyndon B. Johnson.
Who was the only person to serve as both President and chief justice? Taft.
Which President was sworn into office by a woman? Lyndon B. Johnson by Judge Sarah T. Hughes.
Four Presidents were elected whose closest opponent received more popular votes. Who were the Presidents? John Quincy Adams, election of 1824; Hayes, 1876; Benjamin Harrison, 1888; and George W. Bush, 2000.
Who was the first President to visit a foreign country while in office? Theodore Roosevelt.
Which Presidents are buried in Arlington National Cemetery? Taft and Kennedy.
Who were the only grandfather and grandson who both served as President? William H. Harrison and Benjamin Harrison.
Who were the only Presidents to be sworn into office by a former President? Coolidge and Hoover (by Taft).
Which President never married? Buchanan.
Two sons of former Presidents became President themselves. Who were the sons and who were their fathers? John Quincy Adams, son of John Adams, and George W. Bush, son of George H. W. Bush.
Which two former Presidents died on the same day? John Adams and Jefferson.
Which Presidents lived past the age of 90? John Adams, Hoover, and Reagan.
Which President lived the shortest time? Kennedy, 46 years.
Who was the only former Vice President who became President but did not succeed the President under whom he served? Nixon.
Which President had the most children? Tyler, 15.
Who was the first President to live in the White House? John Adams.
Who was the first President to be inaugurated in Washington, D.C.? Jefferson.
Who was the first President to speak on radio? Wilson.
Who was the first President to speak on television? F. D. Roosevelt.
What two Presidents died in the White House? W. H. Harrison and Taylor.
Which President served the shortest time in office? W. H. Harrison, one month, 1841.
Which President served the longest? F. D. Roosevelt, 12 years, 1 month, 8 days.
Which President received the greatest number of electoral votes? Reagan in 1984, 525.
Which Presidents signed the Constitution? Washington, Madison.
Who was the only President who had a child born in the White House? Cleveland, in 1893.
Which Presidents were assassinated? Lincoln, Garfield, McKinley, Kennedy.
Which other Presidents died in office? W. H. Harrison, Taylor, Harding, Franklin D. Roosevelt.
Which Presidents died on the Fourth of July? Jefferson, 1826; John Adams, 1826; and Monroe, 1831.
Who was the first President born after the adoption of the U.S. Constitution? Tyler.
Who was the first President to ride on a railroad train? Jackson.
Who was the only President to resign? Nixon.
Which Presidents served as university presidents before their election to the U.S. presidency? Wilson (Princeton) and Eisenhower (Columbia).
Who was the first President nominated by a national political convention? Jackson.
Who was the youngest person ever to become President? T. Roosevelt, 42.
Who was the youngest person ever elected President? Kennedy, 43.
Who was the oldest person ever elected President? Reagan, 73 years and 274 days when he was elected to his second term.

Philippines, and Puerto Rico. To protect these interests, Theodore Roosevelt built up U.S. military forces. He also warned European nations against interfering in Latin America. Roosevelt broadened the scope of executive power at home by leading a fight for reforms that limited the power of great corporations.

Woodrow Wilson enlarged the presidency during World War I (1914-1918). After the United States entered the conflict in 1917, Wilson rallied public support for the war effort. He won widespread praise for his pledge to help make the world safe for democracy. After the war, he led the drive to set up the League of Nations, an international organization dedicated to maintaining peace.

Perhaps no one expanded the powers of the presidency as much as Franklin D. Roosevelt. He became President during the Great Depression of the 1930's and took extraordinary measures to combat the severe business slump. Roosevelt won public acceptance of his view that the federal government should play a major role in the economy. Largely as a result of strong popular support, he got Congress to adopt a far-reaching program called the New Deal. This program created work for millions of Americans and strengthened the President's role as the nation's legislative leader.

The rapid growth of U.S. military strength during World War II (1939-1945) further increased the influence of the presidency in world affairs. Harry S. Truman's decision to use atomic bombs against Japan during the war showed the tremendous authority of the President.

Another example of this authority occurred in the Cuban missile crisis in 1962. In that crisis, John F. Kennedy carried out negotiations that led to the withdrawal of Soviet missiles from Communist Cuba. The Soviet Union had placed nuclear missiles in Cuba capable of striking U.S. cities. Kennedy demanded the missiles' removal and announced a naval blockade of Cuba. Several days later, the Soviets withdrew their missiles after the U.S. publicly promised to withdraw its nuclear missiles from Turkey and privately agreed not to invade Cuba.

The Vietnam War. The presidency lost much of its prestige during the Vietnam War (1957-1975). Lyndon B. Johnson, who became President in 1963, believed that non-Communist South Vietnam had to be defended against local Communist rebels and Communist North Vietnam. In 1964, Congress allowed him "to take all necessary measures" to protect U.S. bases in South Vietnam.

During the late 1960's and early 1970's, Johnson and his successor, Richard M. Nixon, sent hundreds of thousands of U.S. troops to support South Vietnam. Many Americans opposed United States participation in the Vietnam War. They argued that both Johnson and Nixon had abused presidential powers and misled Congress.

The Watergate scandal further damaged public regard for the presidency. It involved burglary, wiretapping, and other illegal activities designed to help Nixon win reelection in 1972. Attempts by Nixon's aides to cover up many of the activities led to an investigation by the House of Representatives. In 1974, the House Judiciary Committee recommended that Nixon be impeached.

That same year, Nixon lost an appeal to the Supreme Court involving the President's *executive privilege*—the right to keep records secret. The court ruled that executive privilege is not unlimited. It ordered Nixon to release recordings of conversations said to contain evidence for a criminal case in the Watergate scandal. By then, Nixon had lost nearly all support in Congress and faced possible impeachment. He resigned as President on Aug. 9, 1974, and was succeeded by Vice President Gerald R. Ford. No other President has ever resigned.

Many Americans thought Nixon had violated federal laws and wanted him brought to trial. The nation became further divided in September 1974, when Ford pardoned Nixon for all federal crimes Nixon may have committed as President.

The impeachment of Bill Clinton. In 1998, the House impeached President Bill Clinton for perjury and obstruction of justice. The House charged Clinton with lying to a grand jury that was investigating an extramarital affair he had while in office. Other charges included hindering the investigation by lying to his aides and by

Brown Bros.

Presidential election campaigns have changed over the years. Warren G. Harding campaigned from his front porch in Marion, Ohio, in 1920, *left.* President Harry S. Truman toured the nation in a special railroad car during a "whistle-stop" campaign in 1948, *right.*

encouraging others to lie and conceal evidence on his behalf. The Senate acquitted Clinton in 1999.

The presidency today is still strong and important. This is largely because the United States has powerful armed forces and ranks as a leader of the democracies. In addition, the president's ability to reach huge audiences on television adds to the prestige of the office.

Americans look to the president to build morale, recruit talented officials, and explain complex issues. They also expect the chief executive to champion the rights of all Americans regardless of their age, color, political party, religion, region, or sex. At the same time, some Americans dislike the great size and power of the national government and want the president to reduce federal influence over state and local affairs.

Congress and the Supreme Court sometimes act to prohibit or limit actions that they consider a misuse of presidential power. But such challenges have halted the expansion of presidential authority only for limited periods. The presidency will continue to have its ups and downs. But it will remain, as John F. Kennedy once said, "the vital center of action in our whole scheme of government."

Presidential assistant is a person who performs special duties for the president of the United States. The most important assistants work directly for and with the president. Most assistants serve as part of the White House Office, a division of the Executive Office of the President (see **President of the United States** [The Executive Office of the President]).

Presidential assistants aid in nearly every aspect of the president's work. Some help formulate foreign policy. Others help design domestic programs. They provide information and suggestions that help the president make decisions. Others write speeches and develop legislation to propose to Congress. The press secretary handles relations with the media. Assistants recommend appointments to certain government positions. They also help decide which individuals or groups should meet personally with the president.

The modern system of presidential assistants began with President Franklin D. Roosevelt in the late 1930's. The president's responsibilities have grown since then, and so have the number and power of presidential aides. Some critics believe powerful assistants reduce the authority of Cabinet officials. Other observers argue that many issues are broader than the responsibilities of any Cabinet official or executive department, and so the president needs strong aides to help decide them.

Presidents sometimes claim *executive privilege* for their assistants. This doctrine protects assistants from having to testify before Congress, unlike Cabinet offi-

cials, who are required to do so. However, it does not necessarily protect assistants from having to testify in criminal investigations. Critics of the executive privilege doctrine hold that it disturbs the balance of power between the executive and legislative branches by denying Congress information it needs to do its job. Defenders argue that assistants must have such privacy to serve as confidential advisers to the president. I. M. Destler

Presidential libraries collect documents and other items associated with a former United States president. There are 12 presidential libraries. The National Archives administers 10 of them: the George Bush Library in College Station, Texas; the Jimmy Carter Library in Atlanta, Georgia; the Dwight D. Eisenhower Library in Abilene, Kansas; the Gerald R. Ford Library in Ann Arbor, Michigan; the Herbert Hoover Library in West Branch, Iowa; the Lyndon Baines Johnson Library in Austin, Texas; the John Fitzgerald Kennedy Library in Boston; the Ronald Reagan Library in Simi Valley, California; the Franklin D. Roosevelt Library in Hyde Park, New York; and the Harry S. Truman Library in Independence, Missouri. President Bill Clinton announced in 1997 that his presidential library would be in Little Rock, Arkansas. In 2000, Congress approved funding for the Abraham Lincoln Library, to be built in Springfield, Illinois.

The National Archives also administers the official records of the presidency of Richard M. Nixon. These records are kept in Alexandria, Virginia.

The two presidential libraries not managed by the National Archives are the Richard Nixon Library in Yorba Linda, California, and the Rutherford B. Hayes Library in Fremont, Ohio. The Richard Nixon Library and Birthplace Foundation owns and operates the Nixon Library. The Hayes Library is owned by the state of Ohio and operated by the Rutherford B. Hayes Presidential Center.

Many people visit a presidential library to study its books, newspapers, films, photographs, sound recordings, videotapes, and other documents. Each library also includes a museum with exhibits that tell the story of the life and career of the president. The museum of the Gerald R. Ford Library is a separate facility in Grand Rapids, Michigan. John Fawcett

Presidential Medal of Freedom. See Medals, decorations, and orders (Civilian awards; table).

Presidential succession is provided for by Article II and Amendments 20 and 25 of the United States Constitution. Article II states that the vice president shall assume the duties and powers of the president if the president is removed from office, dies, resigns, or is unable to carry out the duties of the office.

Amendment 20, adopted in 1933, provides that the vice president-elect becomes president if the president-elect dies before the term begins but after the Electoral College has met. The Electoral College is a group of representatives chosen by the voters to officially elect the president. If the president-elect dies before the Electoral College meets, the national committee of the victorious political party would select a new candidate. Normally, this candidate would be the vice president-elect, though it need not be. After such a selection, however, the college would vote on that candidate.

If both the president and vice president should die or become disqualified, succession is determined by the Presidential Succession Act of 1947. This law states that the speaker of the House, and then the president *pro tempore* of the Senate, are next in succession. The Cabinet follows in this order:

1. Secretary of state
2. Secretary of the treasury
3. Secretary of defense
4. Attorney general
5. Secretary of the interior
6. Secretary of agriculture
7. Secretary of commerce
8. Secretary of labor
9. Secretary of health and human services
10. Secretary of housing and urban development
11. Secretary of transportation
12. Secretary of energy
13. Secretary of education
14. Secretary of veterans affairs

Under the 1947 law, the secretaries of agriculture, commerce, and labor were added, and the secretary of defense replaced the secretary of war. In 1965, Congress added the secretaries of health, education, and welfare (now health and human services); and housing and urban development to presidential succession. The secretary of transportation was added in 1966, secretary of energy in 1977, secretary of education in 1979, and secretary of veterans affairs in 1989. In 2002, President George W. Bush proposed the creation of a 15th executive department, the Department of Homeland Security. No Cabinet member may become acting president unless the member is a citizen and at least 35 years old. If the member who would logically succeed to the presidency is less than 35, the presidency passes to the next eligible member.

Amendment 25, ratified in 1967, permits the president to nominate a vice president whenever a vacancy exists in that office. The nominee would take office when confirmed by a majority vote of both houses of Congress. The amendment also establishes procedures for temporarily relieving a president who is unable to perform official duties because of an illness or for any other reason. The vice president would become acting president at such times. In 1973, Gerald R. Ford became the first person chosen vice president under Amendment 25. He was nominated by President Richard M. Nixon following the resignation of Vice President Spiro T. Agnew. Ford became president in 1974, after Nixon resigned.

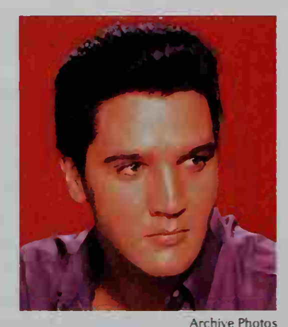
Presidents' Day is an annual holiday observed in the United States to honor the nation's presidents, especially George Washington and Abraham Lincoln. It is celebrated on the third Monday in February. The birthdays of Washington and Lincoln fall near or on the holiday. Washington, the nation's first president, was born on Feb. 22, 1732, according to the calendar we now use. Lincoln, who served as president during the American Civil War (1861-1865), was born on Feb. 12, 1809.

A federal holiday called Washington's Birthday also occurs on the third Monday in February. It became a le-

gal public holiday in 1971. Later, many states adopted Presidents' Day instead, to honor not only Washington, but other presidents as well, especially Lincoln. Presidents' Day is sometimes called Washington-Lincoln Day.

On Presidents' Day, banks, government offices, libraries, and schools close. Most businesses stay open. Many stores hold Presidents' Day sales. Jack Santino



Presley, Elvis (1935-1977), was one of the first American stars of rock music and perhaps the greatest. His popularity continued after his death, rising to almost legendary status.

Elvis Aron Presley was born on Jan. 8, 1935, in Tupelo, Mississippi. During his childhood in Tupelo, he was exposed to the music that shaped his singing style—gospel, country music, and rhythm and blues. When he was 13 years old, he moved with his family to Memphis, Tennessee. At the age of 18, while driving a truck for a living, Presley entered the Sun Records studio run by Sam Phillips in Memphis. Presley stopped in to record two songs, presumably for his mother's birthday. Phillips signed him to a recording contract. Presley's 1954 recording "That's All Right, Mama" became a local hit.

Presley's records sold so well that he attracted the interest of national music companies, especially RCA. Encouraged by Colonel Tom Parker, Presley's manager, RCA bought the singer's contract from Sun Records. Using the enormous resources of RCA, Parker made Presley a national phenomenon. On Sept. 9, 1956, a record number of people watched Presley sing on the Ed Sullivan television variety show. Presley's early hits for RCA included "Heartbreak Hotel" (1956), "Don't Be Cruel" (1956), "Love Me Tender" (1956), "All Shook Up" (1957), "Teddy Bear" (1957), "Loving You" (1957), "Jailhouse Rock" (1957), and "It's Now or Never" (1960). Presley also launched a motion-picture career, beginning with *Love Me Tender* (1956). He made 32 other films.

Presley was particularly popular with teen-agers, who loved his style as well as his music. In particular, they reacted to his sexiness, especially the suggestive way he swiveled his hips as he sang. However, his style also aroused a storm of criticism. Some towns banned his live concerts, and television programs began showing him only from the waist up.

In 1958, Presley was inducted into the United States Army. He spent two years in the Army, primarily in Germany. There he met 14-year-old Priscilla Beaulieu. They were married in 1967 and had a daughter, Lisa Marie, born in 1968. They were divorced in 1973. After his discharge from the military, Presley resumed his motion-picture career and gave up making live appearances. In 1968, believing that the music business was passing him by, he prepared a comeback on television. The program, his first live performance in almost eight years, was so popular that Presley resumed touring. He also recorded such hit songs as "In the Ghetto" (1969) and "Suspicious Minds" (1969). His audience broadened to include older fans in addition to teen-agers.

Archive Photos

Elvis Presley

Presley had made an unsuccessful appearance at a Las Vegas hotel in 1956. He returned to the city in 1969, where he was an enormous success. Until his death, he was the most popular entertainer in Las Vegas.

At first, Presley's return to live performances seemed to energize him. But the pressures of being the "king" of rock music undermined his health. He began taking pills to sleep, to wake up, and to keep his weight down. He died at Graceland, his home in Memphis, at the age of 42. Many people believe drugs hastened his early death.

Since his death on Aug. 16, 1977, Presley has become an even more celebrated figure. The devotion of his fans has become almost religious in its intensity. Graceland has become a major international tourist attraction.

David Rubel

Pre-Socratic philosophy is a term for the theories developed by Greek philosophers from about 600 B.C. to 400 B.C. These philosophers are called *pre-Socratic* because most of them preceded Socrates, the famous philosopher of Athens. The pre-Socratics tried to understand and explain the natural universe in terms of natural principles. They developed conflicting theories but shared a basic interest in the origin and natural processes of the universe. The pre-Socratics laid the foundation for the work of later philosophers.

Scholars know little about the pre-Socratics. Their knowledge comes mainly from fragments of pre-Socratic writings and the works of later writers.

The first pre-Socratics lived in Miletus, a Greek city in Asia Minor, during the 500's B.C. These philosophers believed the universe originated from, and is composed of, one basic substance. The first known pre-Socratic, Thales, taught that water was this substance. Another member of the group, Anaximander, thought the universe came from an eternal stuff that he called the *indefinite.* Anaximenes theorized that air was the basic substance and that it condensed or became less dense to form other materials, such as water or fire.

At about the same time, in what is now southern Italy, Pythagoras explained the universe in terms of numbers. He taught that all things are numbers or, perhaps, could be reduced to numbers. Pythagoras also believed that everything is harmoniously related. On the other hand, Heraclitus saw only strife in the world. He thought that everything constantly changes and moves, and that nothing remains the same.

The teachings of Parmenides, which became influential during the 400's B.C., raised a problem for other pre-Socratics. Until then, philosophers had accepted the existence of change, motion, and *plurality* (reality consisting of many substances). Parmenides held that change, motion, and plurality were unreal because they

require the existence of *what is not.* Parmenides rejected the idea of *what is not* as inconceivable. He said the universe is uniform, immovable, and unchanging, with no generation or destruction.

Parmenides had few followers but great influence. His opponents could not disprove his reasoning, and so they tried to reconcile his conclusions with common sense. Empedocles agreed that there could be no generation or destruction. He explained their apparent existence in terms of four eternal elements—earth, air, fire, and water—mixed by the force of *love* and separated by *strife.* Anaxagoras believed an infinite number of elements had been separated out of an original mixture through the rotation initiated by a force or material he called *Mind.* Each kind of natural substance contains all the elements but in different proportions. Anaxagoras thought matter was infinitely divisible.

In the late 400's B.C., Leucippus and Democritus responded to Parmenides with a theory called *atomism.* They taught that the universe consists of tiny, solid, indivisible bodies called *atoms,* which move about in space and cluster together to form the larger objects of common experience. S. Marc Cohen

Pressburg. See **Bratislava.**

Pressure is often defined as force per unit area. In physics, the term is usually applied to *fluids* (gases or liquids). If a fluid is exposed to suitable forces, pressure is produced in it. The greater the force, the greater the pressure. Pressure is measured in pounds per square inch in the inch-pound system customarily used in the United States. It is measured in kilograms per square centimeter or pascals in the metric system.

Atmospheric pressure is produced by the weight of the air from the top of the atmosphere as it presses down upon the layers of air below it. At sea level, the average atmospheric pressure is 14.7 pounds per square inch (101.3 kilopascals). This decreases with altitude because of less air pressing from above.

If a fluid is at rest, pressure is transmitted equally to all its parts and, at any one point, is the same in all directions. The fluid acts this way because the molecules in it move freely. The molecules are far apart in a gas and comparatively close together in a liquid.

The French scientist Blaise Pascal discovered the fact that pressure in a fluid is transmitted equally to all distances and in all directions. He formulated *Pascal's law* to describe the effects of pressure within a liquid (see **Pascal's law**). This law has many practical applications.

The greater the pressure in a gas, the smaller its volume. This decrease in volume occurs because the molecules are pushed closer together. Under ordinary conditions, the volume of a gas decreases by half when the pressure doubles. The law that describes how the volume of a gas changes when the pressure changes is called *Boyle's law,* after Robert Boyle, the Irish scientist who first developed it. The volume of liquids and solids also decreases when pressure increases, but by very much smaller amounts than for gases.

The ability of a gas to compress and expand has many practical uses. For example, air tires, air cushions, and air brakes are based on this elasticity of air.

Pressure changes the boiling point of water. The boiling point is that temperature at which the pressure of the steam is equal to the atmospheric pressure. At sea level, the two pressures are equal at 100 °C or 212 °F. As height increases, the pressure decreases, and the boiling point becomes lower. This makes cooking at high altitudes difficult, because cooking depends on the temperature to which the food is heated, not on whether the surrounding water is boiling. See **Boiling point.**

Wind is the movement of air from a point of high pressure to a point of low pressure. Pressure changes precede storms. Barometers detect storms by measuring such changes. Gregory Benford

Prester John (or *Presbyter John*) was a legendary Christian priest and king. He is supposed to have lived in the 1100's. Many travelers of the Middle Ages, including Marco Polo, claimed that he ruled a vast kingdom in central Asia. Later reports, especially by Portuguese explorers, made him the emperor of Ethiopia. Pope Alexander III sent a messenger to look for him in 1177, but the messenger never returned. Stanley K. Stowers

Pretoria, *prih TOHR ee uh* (pop. 525,583), is the administrative capital of South Africa. The executive branch of the government directs the country's administrative affairs from Pretoria. Cape Town is South Africa's legislative capital, and Bloemfontein is the judicial capital. In 2000, Pretoria became part of the newly created City of Tshwane Metropolitan Municipality. Tshwane has a population of about 1,800,000. For Pretoria's location, see **South Africa** (political map).

Many Pretoria residents hold government jobs. Others work in railroad workshops, and in factories that make cement, chemicals, machinery, motor vehicles, and plastics. Pretoria is a leading cultural and research center. It has a number of museums and art galleries, the national zoo, and three universities.

Boers (now called Afrikaners), who are people mainly of Dutch descent, founded Pretoria in 1855. When the Union of South Africa was formed in 1910, Pretoria became the administrative capital. Peter Sullivan

Pretzel is a type of German biscuit. It is brittle and twisted, with a glazed, salted surface. According to tradition, the first pretzels were made in the early 600's by European monks as a reward for children who learned their prayers. The original pretzel's shape represented the crossed arms of a child praying. The first commercial pretzel bakery in the United States opened in Lititz, Pennsylvania, in 1861. Kay Franzen Jamieson

Prevailing westerly is a wind that blows over the north and south middle latitudes from west to east. In the Southern Hemisphere, prevailing westerlies over the ocean blow with such force that sailors call this region the "roaring forties." The winds are not steady because they are often interrupted by cyclonic storms. Over the land masses of the Northern Hemisphere, the westerlies are often turned from their course by moun-

tain ranges. The United States and the southern half of Canada lie within the westerlies' path. Mark A. Cane

Prévert, Jacques (1900-1977), was probably the most popular French poet of the mid-1900's. His popularity resulted almost entirely from one volume, *Paroles (Spoken Words),* which became an immediate best seller when it appeared in 1946. Prévert's poems are rich in the clever use of words and humor. They declare the need for individual happiness and love, and attack with playful mockery the most respected human institutions. The simple sentence structure of many of the poems makes them favorites in beginning French courses.

Prévert was born in Neuilly-sur-Seine. He joined the Surrealist movement during the 1920's, and his poems reflect the fantasy and freedom of expression typical of Surrealism. Prévert also wrote the scripts for several films directed by Marcel Carné. Jean-Pierre Cauvin

Previn, *PREH vuhn,* **André,** *ahn DRAY* (1929-), is an American conductor, pianist, and composer. Previn served as conductor of the Houston Symphony Orchestra from 1967 to 1969. He conducted the London Symphony Orchestra from 1968 to 1979. He was music director of the Pittsburgh Symphony Orchestra from 1976 to 1984. Previn served as the music director of the Royal Philharmonic Orchestra from 1985 to 1988 and the Los Angeles Philharmonic Orchestra from 1985 to 1990.

As a pianist, Previn achieved success playing both classical music and jazz. He composed and arranged music for several films and recordings, and he received four Academy Awards for his film work. Previn has also composed concertos and other classical pieces.

Previn was born in Berlin, Germany. His family settled in the United States in 1939. He became an American citizen in 1943. He described his movie career in *No Minor Chords: My Days in Hollywood* (1991). John H. Baron

Priam, *PRY uhm,* in Greek mythology, was the last king of Troy and ruler of the city during the Trojan War with Greece. He was noted for his kindness, dignity, and respect for the gods. Priam's wife was Hecuba (or Hecube). By her and various other women, Priam had 50 sons and 50 daughters. The most famous were the sons Hector and Paris and the daughter Cassandra.

Most of Priam's sons died in the war. The king went alone at night to the tent of the Greek warrior Achilles to beg for Hector's body so he might give it a proper burial. Achilles pitied the old man and returned the body to him. Later, as Priam clung to the altar of Zeus on the night that Troy fell, Achilles's son Neoptolemus (or Pyrrhus) killed him. Justin M. Glenn

See also **Hecuba; Iliad; Paris** (mythology).

Pribilof Islands, *PRIHB uh LAWF,* are four hilly islands in the Bering Sea. They are the home of the world's largest fur seal herd. Each spring, about 1 $\frac{1}{2}$ million fur seals go to the Pribilofs to breed. The Pribilofs include the large islands of St. Paul and St. George, and the smaller islands of Otter and Walrus. They cover 76 square miles (197 square kilometers) and have about 700 people. The United States obtained the islands when it bought Alaska in 1867. For location, see **Alaska** (physical map).

For many years, there were no restrictions on hunting the seals. As a result, they almost became extinct. In 1911, the United States, Russia, the United Kingdom, and Japan signed a treaty in which they agreed to protect the seals, and the United States received charge of the herd. In 1957, the United States, Canada, the Soviet Union, and Japan agreed to restrict seal hunting to the Pribilofs and two Soviet islands. The treaty expired in 1984. Since then, animal protection laws have prevented commercial hunting of fur seals around the islands.

In 1786, the Russian explorer Gerasim Loginovich Pribylov (also spelled Pribilof) discovered the islands. They were then uninhabited. Russian traders brought Aleuts from the nearby Aleutian Islands to the Pribilofs to help hunt seals. The Aleuts continued to settle there. Today, St. Paul has more than 500 people. It is Alaska's largest Aleut community. Claus-M. Naske

Price is the amount of money for which something can be bought or sold. The price states the worth in money of a unit of a certain good or service. This article discusses how prices are determined and what prices do in *free market systems.* These systems, in which people carry out their economic activities largely free from government control, operate in the United States and Canada. In *planned economies,* such as those of Communist nations, the government often determines prices.

How price is determined

Demand and supply. Prices are based on the economic forces of *demand* and *supply. Demand* is the quantity of a good or service that consumers are willing and able to buy. *Supply* is the quantity producers and other people are willing and able to offer for sale.

Demand usually varies with a product's price. The lower the price, the greater the demand. This is because people who want the product will buy more of it at a lower price and because the low price will attract new buyers. The tastes and incomes of buyers and potential buyers also determine demand. In addition, demand for one product may be affected by the prices of related products. For example, if an increase in the price of automobiles causes people to buy fewer cars, there will be less demand for automobile tires.

Supply also varies with prices, but in the opposite way from demand. Often, the higher the price, the greater the quantity producers want to supply. But the main determiner of supply is the cost of production, which depends primarily on the costs of labor, materials, and capital. The cost of production may rise or drop as greater quantities are produced, with an associated price change. But this cost and the price may also stay about the same, as greater quantities are produced.

In a free market system, the price of a product tends to settle at an *equilibrium price.* This is a price at which buyers are able to purchase all they want, and at which sellers are able to sell all they wish to sell. As the conditions of supply and demand change, the equilibrium price moves up or down.

Monopoly. The price of a product may be affected by special circumstances. For example, a business firm may gain a *monopoly*—that is, it may control the supply of a product for which there is no close substitute. The firm then may use its *monopoly power,* or *market power,* to raise the product's price. It may raise the price above whatever equilibrium price would have been achieved under competition. Because there are no close substitutes for the product, consumers who want the product will have to pay the high price.

Government intervention in the market, through *price controls* or other means, also affects prices. Various price controls may benefit producers or consumers. A *price ceiling* is a maximum price that is designed to help a certain group of consumers. For example, some city governments put price ceilings on rental units to limit the amount of rent a landlord may charge a tenant. A *price floor* is a minimum price established by a government. This price is designed to aid certain producers. For example, the U.S. government has established price floors, known as *support prices,* for many agricultural products in *price support programs* to help farmers gain profits. The government helps to maintain a support price partly by buying certain quantities of the product and thereby increasing demand.

The government also may use other types of price controls, such as a *price freeze.* This method holds prices at a certain level, such as the level they were at when the price freeze went into effect.

Although interventions help solve some problems, they may cause others. For example, an effective support price is set above the equilibrium price and a *surplus* of the product will result. Low prices caused by price ceilings may cause shortages by increasing demand for a product or by decreasing supply.

What prices do

In a free market system, an equilibrium price *clears the market*—that is, it satisfies buyers and sellers. Price systems thus ration products, distributing them to people willing and able to pay for them.

Prices help determine what goods and services should be produced, how they should be produced, and for whom they should be produced. Consumers let producers know what to produce by indicating the prices they are willing to pay for particular goods and services. Producers decide how to produce goods and services based on the prices of materials and labor. How much people can afford to buy determines for whom goods are produced. Irving Morrissett

Price, Hugh Bernard (1941-), became president of the National Urban League in 1994. Before taking the post, he had served since 1988 as a vice president of the Rockefeller Foundation, a charitable organization.

Price was born in Washington, D.C. He graduated from Amherst College in 1963 and Yale Law School in 1966. He then worked until 1968 as a lawyer with the New Haven Legal Assistance Association in New Haven, Connecticut. The association provided free legal service to poor people. From 1968 to 1970, Price headed a political group called the Black Coalition of New Haven. From 1970 to 1975, he was a partner in an urban affairs consulting firm in New Haven. Price then worked as human resources administrator for the city in 1977 and 1978.

In 1978, Price joined the editorial board of *The New York Times.* As a member of the board until 1982, he wrote editorials on such issues as criminal justice, education, and welfare. From 1982 to 1988, Price was a senior vice president of WNET-TV, a public television station in New York City. Hanes Walton, Jr.

See also **Urban League.**

Price, Leontyne, *LEE uhn TEEN* (1927-), an African American singer, ranks among the most celebrated sopranos of her time. Her brilliant voice has an exciting vibrating quality and an unusually wide range. Price has gained acclaim both for her concert recitals and for her opera performances. The title role in the opera *Aida* is perhaps her most famous operatic part. Her performance in the role in 1960 at La Scala in Milan, Italy, made her internationally famous. She was the first black woman to sing a leading role with that famous opera company.

Price was born in Laurel, Mississippi. She made her first appearance at the Metropolitan Opera in New York City in 1961 in *Il Trovatore.* She received the Presidential Medal of Freedom in 1964 and the Spingarn Medal in 1965. Price retired as an opera performer in 1985, but she has continued to sing recitals. Charles H. Webb

Price control is a method used by a government to influence prices for the benefit of producers or consumers. Price controls are often used to prevent prices from rising too rapidly. A government may use price controls in several ways. It may establish the maximum price that can be charged for certain goods or services. It may freeze prices where they were when the controls became effective. Or a government may establish a minimum price that can be charged.

Governments may use price controls to fight *inflation,* a decrease in the purchasing power of money (see **Inflation**). Inflation benefits some people at the expense of others, and so it can disrupt production and cause social disorder. For example, workers may strike for higher pay if the cost of living rises faster than wages.

Price controls have been used chiefly during wartime, when heavy government spending makes inflation most dangerous. The United States and Canada imposed price controls during World War II (1939-1945). The United States used price controls less successfully during the Korean War in the early 1950's. The success of price controls depends primarily on how vigorously the government enforces the price controls and on public cooperation. Irving Morrissett

See also **Rationing; World War II** (On the home front).

Prickly-ash is the name of a large group of trees or shrubs found mainly in tropical regions. Prickly-ashes are not true ash trees. The name refers to the leaves, which resemble those of true ashes (see **Ash**). Prickly-ashes have sharp spines on the twigs and fragrant bark.

Several species of prickly-ashes grow in the United States. The *southern prickly-ash,* also known as *Hercules club,* is a small tree with a warty trunk. It grows in sandy soil from Virginia to eastern Texas. It is also called the *toothache tree* because the bark produces a cooling and numbing sensation when chewed and has been used as a painkiller for toothache. The *northern prickly-ash,* also called *common prickly-ash,* grows in dry, rocky woods or lowland areas, mainly in the eastern and central United States. It contains an oil used in some medicines.

Scientific classification. Prickly-ashes belong to the family Rutaceae. The scientific name for the southern prickly-ash is *Zanthoxylum clavaherculis.* The northern prickly-ash is *Z. americanum.* Michael J. Baranski

Prickly heat is a skin rash of tiny, red pimples that itch. It is also called *heat rash.* It may appear often when the weather is warm and moist. The rash occurs when sweat pores are blocked so that sweat cannot reach the surface of the skin. Prickly heat is common among infants. It is relieved by keeping the skin cool with cool compresses and mild dusting powders. The disorder is annoying but not harmful. Yelva Liptzin Lynfield

Prickly pear, also called *nopal* or *Indian fig,* is a type of cactus with prickly fruits that are shaped somewhat like a pear or fig. Many species of prickly pears grow in dry parts of the southwestern United States and northern Mexico. They can stand long periods with little water, but they grow better with moderate rainfall, as in parts of Florida, southern Brazil, and northern Argentina.

The stem of the prickly pear consists of a series of flat, leaflike segments called *joints.* The flowers and fruit grow on the edges of the joints. In Mexico and Central America, the edible kinds are called *tuna.* The fruits are common in markets throughout Latin America. Luther Burbank developed spineless varieties, which are raised as food for people and livestock.

Prickly pears have been introduced into Mediterranean countries, India, Sri Lanka, South Africa, the Canary Islands, and Madagascar. The chief reason for their widespread cultivation is their food value and, formerly, their use in the cochineal dye industry. The cochineal insect, which gives a red dye, feeds on prickly pears.

One species of prickly pear was brought to Australia in 1788 for a cochineal dye industry that was never established. Later, two other species were brought there as curiosities. From 1900 to 1925, they spread so quickly that they made about 30 million acres (12 million hectares) useless for crops or grazing. The Australian government then brought in an Argentine moth, *Cactoblastis cactorum.* Its larvae live in the joints and destroy them. Within seven years, the heavy growth of prickly pears had been almost destroyed. Philip W. Rundel

Scientific classification. Prickly pears belong to the cactus family, Cactaceae. They are members of the flat-stemmed group of genus *Opuntia.*

See also **Flower** (picture: Flowers of prairies and dry plains); **Cactus** (picture).

Priest, in many religions, is the title of certain members of the clergy. A priest primarily performs religious ceremonies and gives religious advice.

Religions that have a priesthood include Buddhism, Hinduism, Shinto, and Taoism. In Christianity, the Anglican, Eastern Orthodox, Mormon, Roman Catholic, and Scandinavian Lutheran denominations use the term *priest.* Many of these priests serve as pastors of local churches. In ancient times, Judaism had a class of priests, led by a high priest (see **High priest**). Today, however, Judaism has no priesthood.

Many religions teach that priests have special authority to transmit sacred power to others through ceremonies. In Hinduism, only *Brahmans* (priests and scholars) may perform ceremonies involving reciting lines from scriptures known as the Vedas. Hinduism teaches that these scriptures have special powers.

Some religions limit the priesthood to certain families or classes. In other religions, dreams or other signs are used to choose priests. Many religions exclude women from the priesthood. In most cases, a person must study to enter the priesthood. Robert S. Ellwood, Jr.

See also **Bishop; Celibacy; Minister.**

Priestley, John Boynton (1894-1984), was a British novelist, playwright, and journalist who wrote novels in the realistic tradition of the 1800's. His best-known novel is *The Good Companions* (1929), an amusing story of a wandering music-hall troupe. His nostalgic novel *Lost Empires* (1965) also concerns the music-hall world. *Angel Pavement* (1930) is a more serious novel about London's business world. Priestley wrote much nonfiction, including *Literature and Western Man* (1960). His most popular plays include *Dangerous Corner* (1932) and *An Inspector Calls* (1945), satires on middle-class life. *Time and the Conways* (1937) is a science-fiction play.

Priestley was born Sept. 13, 1894, in Bradford, Yorkshire. After graduating from Cambridge University, he became a journalist in London in 1922. Sharon Bassett

Priestley, Joseph (1733-1804), a British clergyman and chemist, shares the credit for the discovery of oxygen with Carl Wilhelm Scheele of Sweden (see **Oxygen**). Priestley called the gas "dephlogisticated air." French chemist Antoine Lavoisier named it *oxygen.*

Priestley was born near Leeds, England, on March 13, 1733. He studied for the ministry. After preaching in Suffolk and Cheshire, he taught at the *dissenting* (nonconformist) academy in Warrington. Ordained in 1762, he became a dissenting minister in Leeds and Birmingham.

At Warrington, with the aid of Benjamin Franklin and others, Priestley wrote his first scientific work, describing his experiments with electricity. Priestley turned to chemistry in the late 1760's. He discovered oxygen in 1774 and published an account of his discovery in 1775. Priestley also isolated and identified nitrous oxide (laughing gas) and sulfur dioxide.

Priestley's sympathies for the cause of the French Revolution made him unpopular in England. In 1791, an angry mob burned his home and chapel in Birmingham. Priestley left England and moved to the United States in 1794. He settled permanently in Northumberland, Pennsylvania. Seymour Harold Mauskopf

Primakov, *pree muh KAWF,* **Yevgeny Maksimovich,** *yehv GEH nee mak SIHM uh vihch* (1929-), was prime minister of Russia from 1998 to 1999. He had served as minister of foreign affairs from 1996 to 1998.

Primakov was born Yona Finkelstein in Kiev, Ukraine, then part of the Soviet Union, on Oct. 29, 1929. He spent his childhood in Tbilisi, Georgia, also a part of the Soviet Union at that time. He changed his name as a youth. He graduated from the Moscow Institute of Oriental Studies in 1953 and received a doctorate in economics from Moscow State University in 1956.

Primakov joined the Communist Party in 1959. From 1962 to 1970, he worked for the Communist newspaper *Pravda.* He served as the Middle East correspondent and became fluent in Arabic. In the 1970's and 1980's, he held administrative posts with the Soviet Academy of Sciences and advised Soviet leaders on foreign policy.

In 1991, Primakov became head of the foreign intelligence branch of the KGB, the Soviet intelligence agency. After the Soviet Union dissolved in December of that year, he became head of Russia's Foreign Intelligence Service. He held that post until 1996. Donald J. Raleigh

Primary color. See **Color** (Methods of color production).

Primary election is a method of selecting candidates to run for public office. In a primary election, a political party, in effect, holds an election among its own members to select the party members who will represent it in the coming general election. Any number of party members can run for an office in a primary. But only the winning candidate can represent the party in the general election. Parties learn from the primary votes which candidates the members of their parties prefer. When several candidates enter a primary, the winner may receive less than 50 percent of the vote. Some states, especially in the South, then hold a *run-off primary*, in which the two candidates with the highest number of votes run against each other.

Direct and indirect. The *direct primary* is the most common form of primary election. In the direct primary, party members who want to run for office file petitions to have their names placed on the ballot. Voters then vote directly for the candidates of their choice. In an *indirect primary*, party members vote for delegates to party conventions, where candidates are chosen.

Open and closed. A primary election is considered *closed* when each voter must declare a choice of party, either when registering to vote or when voting. Party members can vote only for candidates on their party's ballot, and their party's contest is closed to members of other parties. In an *open primary*, the voter receives ballots for all the parties in the election, and chooses both party and candidates in the voting booth. A few states hold a primary called a *blanket primary*, in which voters may choose candidates from different parties.

Nonpartisan primaries are often used for judicial, school board, and local elections. Candidates are listed on the ballot with no indication of political affiliation. The voters choose candidates on the basis of their individual merits, not their party membership. The candidates with the greatest numbers of votes become the opposing candidates in the general election.

The presidential primary is used in over half of the states to choose delegates to the national party conventions. Each candidate who enters the election lists a slate of delegates who have promised to support the candidate at the convention. The party members show their choice for the presidential nomination by voting for the slate of delegates committed to that candidate. Primaries that select about two-thirds of the delegates are held in the first six months of presidential election years.

History. Before primary elections were used, political parties nominated candidates for office at party conventions and caucuses. Political bosses often hand-picked candidates, making shady deals to win enough votes. People gradually turned against this system as being undemocratic and open to corruption. Reform movements urged "No More Boss Rule" and "Down with King Caucus!"

In 1903, Wisconsin passed the first statewide primary law. Within 10 years, most states did likewise. Today, every state uses some form of primary election for statewide offices. Several states still use caucuses to nominate presidential candidates. Robert Agranoff

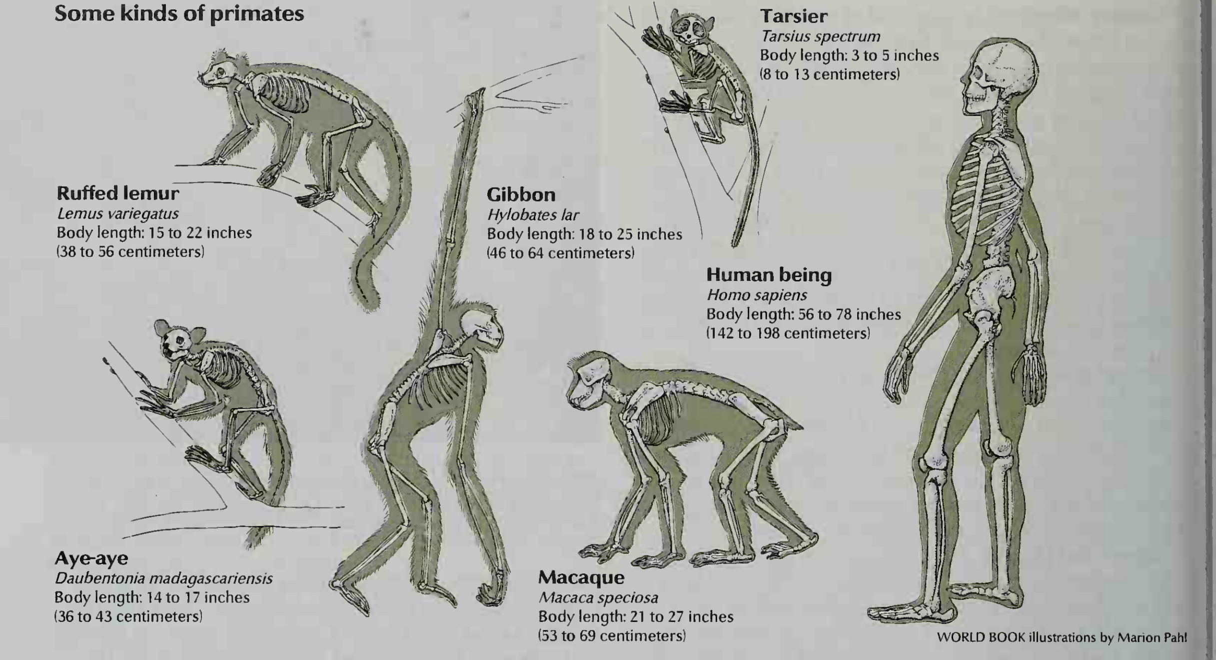
Primate is a member of the group of mammals made up of human beings and the animals that most closely resemble them. Scientists classify about 230 living *species* (kinds) of mammals as primates. These diverse animals range in size from 1 ounce (28 grams) to almost 400 pounds (181 kilograms). Most primates belong to one of two major groups, commonly known as *prosimians* and *anthropoids*. Prosimians include lemurs and generally have a smaller body size than other primates. Anthropoids consist of monkeys, apes, and human beings. One small group of primates, the *tarsiers*, have characteristics of both prosimians and anthropoids. But scientists consider them more closely related to anthropoids. Biologists classify anthropoids and tarsiers in a group called the *Haplorhini*, and prosimians in a group called the *Strepsirhini*.

© Michael Fogden, Animals Animals

Primates are social animals that commonly live in trees. The tarsiers pictured here inhabit forests of Southeast Asia. They are active at night and have huge eyes for excellent night vision.

Primates share certain traits in common. The first primates evolved as tree-living animals. Thus they developed grasping hands that enabled them to hang onto branches and move easily from branch to branch. Most primates also have grasping feet, and some even have grasping tails. Primate eyes face forward, providing excellent vision. Most species rely on sight more than they do hearing or smell.



In general, primates have large brains and rank among the most intelligent and social of animals. Many species live in large, complex social groups. Most primate young take a long time to mature, so they rely heavily on their mother. The young learn much from her, including what to eat and what things to avoid.

Most scientists believe that the earliest primates evolved around 65 million years ago. Nonhuman primates once occupied more of North America, Europe, and Asia than they do today. At present, almost all nonhuman primates inhabit tropical climates in Africa, Asia, and South America. Many of them have become threatened with extinction.

Kinds of primates

Prosimians are the more primitive of the two groups of primates. Most prosimians, including lemurs, live on the island of Madagascar off the southeast coast of Africa. Other prosimians inhabit Asia and continental Africa. These include galagos, lorises, and pottos.

Some kinds of primates

WORLD BOOK illustrations by Marion Pahl

Lemurs are the most diverse group of prosimians. The smallest lemur, the pygmy mouse lemur, weighs about 1 ounce (28 grams). The largest lemur, the indri, weighs about 20 pounds (9 kilograms). Lemurs have projecting front teeth that form a "tooth comb," which they use to groom themselves and each other. They also use a claw on the second toe of each foot for grooming. Many lemurs have long lower limbs and short upper limbs, enabling them to leap gracefully from branch to branch.

Lemurs live in social groups that often vary from 10 to 20 individuals. Some species are *diurnal* (active during the day), while others are *nocturnal* (active at night).

Aye-ayes rank among the rarest of all primates. These nocturnal lemurs grow to about 7 pounds (3 kilograms) in weight. They search for insects, an important food, using some remarkable body features. First, they gnaw through tree bark with their incisors, which grow continuously. Then they use a long claw on the third finger of each hand to probe for insects within the tree. Unlike other lemurs, aye-ayes live alone.

Galagos and lorises are two closely related types of nocturnal prosimians. Both live in Africa, but lorises also inhabit India and Southeast Asia. Like the lemurs, galagos and lorises have "tooth combs" and a grooming claw on the second toe. Galagos have remarkable leaping ability. Though these primates measure only 4 to 18 inches (10 to 46 centimeters) long, some can jump over $6\frac{1}{2}$ feet (2 meters). Lorises, however, move slowly in the trees.

Tarsiers are small, nocturnal primates of Southeast Asia. They resemble prosimians in some respects and anthropoids in others. Scientists once thought tarsiers were closer to prosimians in their evolutionary history and anatomy. But now many biologists classify them closer to the anthropoids. The tarsiers' nocturnal lifestyle resembles that of many prosimians. Tarsiers have huge eyes for excellent night vision. Each of these eyes is bigger than their brain. Tarsier skulls, however, resemble those of anthropoids more than those of prosimians. Tarsiers also have big hands and feet. Their hands help them to catch prey, while their feet enable them to execute dramatic leaps in the forest.

Anthropoids constitute a much larger and more diverse group than do prosimians. They consist of six scientific families. Two families of *New World monkeys* range from Mexico through South America. Three other families—the *Old World monkeys,* the *lesser apes,* and the *great apes*—inhabit Africa, Europe, and Asia. Human beings live throughout the world.

The bodies of anthropoids differ from those of prosimians. In monkeys, apes, and human beings, the two sides of the lower jawbone are fused together. These sides remain unfused in prosimians. Anthropoid and prosimian skeletons also differ. Most monkeys and apes have longer, better developed upper limbs than do prosimians, enabling them to walk on all four limbs and swing from the branches of trees. Unique among anthropoids, human beings possess long lower limbs and relatively short upper limbs for walking full-time on two legs. While prosimians have a well-developed sense of smell, anthropoids rely more on sight, and most of them have color vision. With the exception of the owl monkey of South America, anthropoids sleep at night and remain active during the day.

New World monkeys inhabit the forests from southern Mexico to northern Argentina. They have evolved separately from other monkeys for about 20 million years.

New World monkeys possess certain body features that distinguish them from Old World monkeys. For example, the nostrils of New World monkeys generally lie farther apart than those of their Old World cousins. Some New World monkeys, such as the howler monkeys, have a *prehensile tail* that can "grasp" branches as a hand does, enabling the animals to hang by their tail.

Prehensile tails have well-developed muscles and sensitive fingerprint skin at the tip. New World monkeys generally possess smaller, less useful thumbs than do Old World monkeys. Some species, including certain spider monkeys, have lost their thumbs completely.

Two unusual types of New World monkeys, the marmosets and tamarins of South America, rank among the smallest primates. Marmosets weigh from 10 to 12 ounces (300 to 350 grams), and tamarins weigh from 12 to 27 ounces (360 to 790 grams). They differ from other New World monkeys in that they have only two molars on each side of their upper and lower jaws. All other anthropoid primates have three. For this reason, scientists classify marmosets and tamarins in a separate family.

All New World monkeys live in trees, but different species occupy different layers of the forest canopy. New World monkeys live in a variety of social groupings. A number of them, including the woolly monkey, gather in groups of up to 70 individuals. Marmosets and others live in small communities of 15 or less.

Old World monkeys live in Africa, Asia, and Europe. Most of these primates have a callous pad of skin on their rumps, which enables them to sit and sleep more comfortably in trees. They also tend to grow larger on average than New World monkeys, and numerous species spend at least part of their time on the ground.

Old World monkeys consist of two groups: the *colobines* and the *cercopithecines.* Colobines include the langurs of Asia and the colobus monkeys of Africa. Colobines eat primarily leaves, which they digest with their large multichambered stomachs. But like all primates, leaf-eaters also consume other types of food. Colobines have longer legs, shorter thumbs, and longer tails than do cercopithecines.

Cercopithecines include the macaques, which live in Asia, Africa, and Europe; and the baboons, mangabeys, and guenons of Africa. Cercopithecines have simpler stomachs. They also have cheek pouches that they can stuff with food for temporary storage.

Old World monkeys inhabit a diverse range of climates, including deserts, tropical rain forests, and colder mountainous regions. The Japanese macaque of Japan lives farther north than any other nonhuman primate. A number of Old World monkeys form complex social groups. Baboons, for example, gather in groups of up to 90 individuals. This larger gathering consists of several smaller groups of about five females and a dominant adult male. Baboons spend more of their lives on the ground than any other monkey.

Lesser apes include the gibbons and the siamang of Southeast Asia. These primates, along with great apes and human beings, have no tail. Gibbons and siamangs also have extremely long upper limbs. Their long arms enable them to hang acrobatically under branches and swing from branch to branch. They also walk *bipedally* (on two legs) high in the trees. Biologists call gibbons and siamangs "lesser apes" because they grow about the same size as many monkeys. Lesser apes also have sitting pads on their rumps, as have Old World monkeys. Gibbons and siamangs mate for life in the wild. They eat mostly fruits and leaves.

Great apes include the orangutan of Southeast Asia and the bonobo, chimpanzee, and gorilla of Africa. Great apes have no tail and, unlike lesser apes, they lack sitting pads on their rumps. Thus they need to build nests in the trees or on the ground for sleeping. Great apes are more closely related to human beings than any other type of primate.

The orangutan ranks as the largest *arboreal* (tree-dwelling) animal. Males weigh on average 180 pounds (80 kilograms), while females average 81 pounds (37 kilograms). Orangutans inhabit rain forests on the Southeast Asian islands of Borneo and Sumatra. Because of their arboreal existence, orangutans have developed huge hands and feet with long, curved fingers and toes. They also have long, powerful upper limbs and extremely flexible joints, especially in the shoulders, hips, wrists, and ankles. Orangutans live more solitary lives than do most other primates. Males forage alone for fruit, their main food, and the only social bonds occur between females and their offspring. Adult males and females interact only to mate.

Gorillas grow larger than any other primate. Some wild male gorillas weigh as much as 390 pounds (177 kilograms). Females weigh about half as much as males. The three subspecies of gorilla—the *mountain gorilla,* the *eastern lowland gorilla,* and the *western lowland gorilla*—all live in central Africa. Gorillas spend most of their time on the ground and eat largely plant foods. They usually live in small groups. Most social interaction occurs between females and their young or between adult males and adult females.

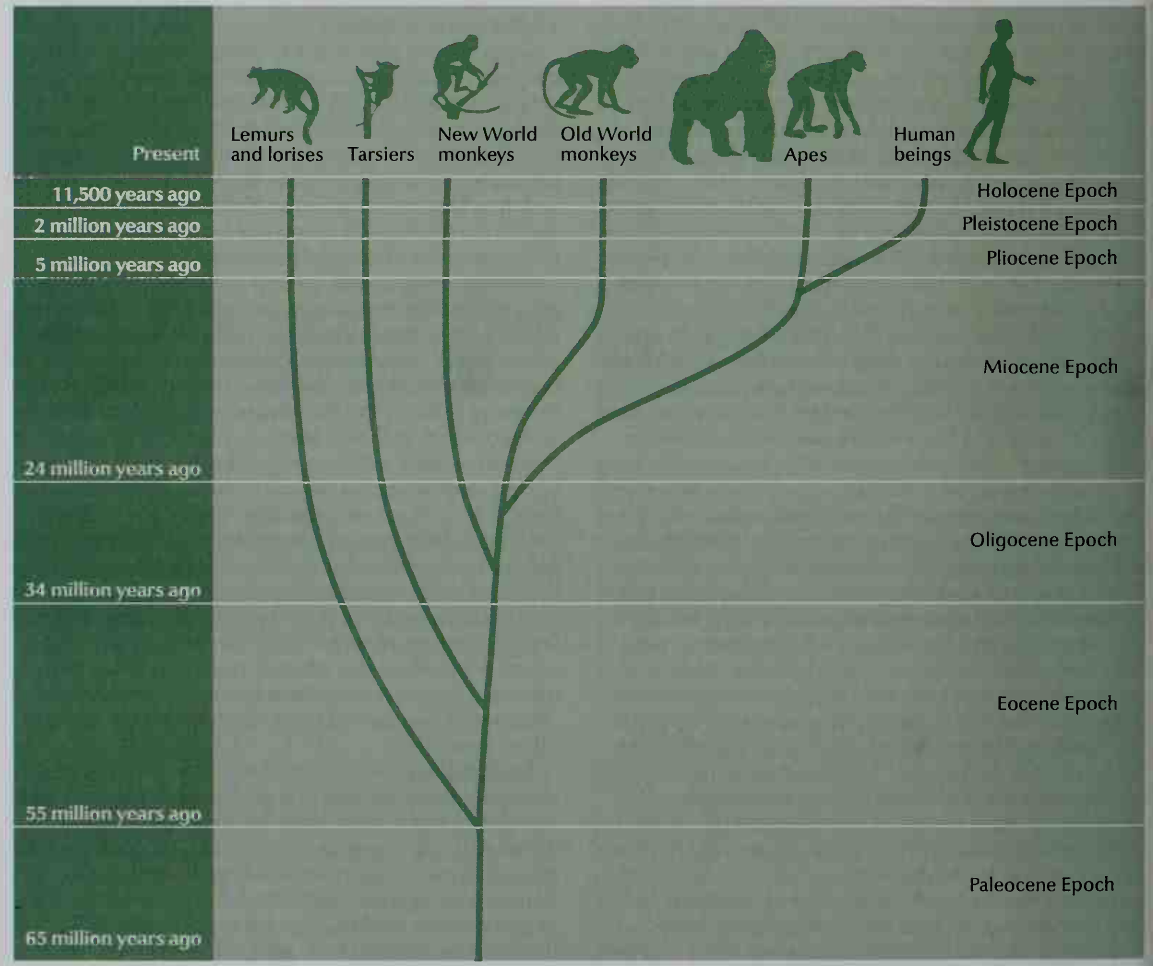
Chimpanzees are the most widely distributed of all the great apes. They range from dry woodlands in western and eastern Africa to humid rain forests in the Congo Basin of central Africa. Chimpanzees spend part of their day in the trees and part on the ground. They eat primarily fruit, but they also consume leaves and insects and even hunt for monkeys and other mammals. Males usually do the hunting in small groups and try to keep the meat for themselves. Other chimpanzees gather around the hunters and get some of the meat by begging or stealing. In chimpanzee societies, males and females form separate groups at times and live together at other times. Chimpanzee behavior also includes activities that scientists once thought only human beings performed, including using tools and engaging in warfare with others of their own kind.

Bonobos, also called pygmy chimpanzees, live south of the Congo River in Congo (Kinshasa). Bonobos closely resemble chimpanzees but differ from them in many ways. Bonobo social groups consist of small bands of males, females, and young. When fruit becomes abundant, several groups may form temporary communities of up to 75 individuals. Bonobos exhibit a much lower level of aggression within their groups than do chimpanzees. Bonobos also spend more time in the trees than their close relatives. Bonobos and chimpanzees share more characteristics with human beings than any other animal does.

Human beings rank as the most widespread of all primates. They are the only primates that permanently walk *bipedally* (on two legs). They also have the most highly developed brain, and they live in the most complex societies. These societies have developed sophisticated *cultures* (ways of behaving and thinking). However, the rapid growth of human populations represents a major threat to the survival of all other primates.

The evolution of primates

Primates have a long evolutionary history that spans roughly the last 65 million years. The first known primate, called *Purgatorius,* probably developed in what is now North America during the end of the Cretaceous Period and the beginning of the Paleocene Epoch. Scientists know little about *Purgatorius* because only a few fossil jaws and teeth have been found. From the middle to late Paleocene, slightly more evolved primates called *plesiadapiforms* appeared. This diverse group of small mammals resembled rodents or shrews. They inhabited North America and Europe.



Modern primates evolved in the first part of the Eocene Epoch, approximately 56 million years ago. Two groups, the *adapids* and the *omomyids,* emerged at this time, becoming more abundant than earlier primates. Some scientists believe that adapids evolved into the first monkeys and apes. Other scientists consider the omomyids to be the true ancestors of monkeys and apes.

According to fossil evidence, both the adapids and omomyids more closely resembled living primates than did plesiadapiforms. They had larger brains, shorter faces, and a bony ring encircling each eye. Adapids and omomyids relied more on sight and less on smell than did earlier primates. They also developed hands and feet that could more easily grasp tree branches and other objects.

During the end of the Eocene Epoch and the beginning of the Oligocene Epoch—from about 40 million years ago to about 34 million years ago—the first true monkeys appeared in the Eastern Hemisphere. Scientists have discovered a few fossil primates in Southeast Asia from the Eocene Epoch, including *Amphipithecus, Eosimias,* and *Pondaungia.* These primates may represent the oldest anthropoids. But many scientists still believe animals called *parapithecids,* from the Oligocene Epoch in what is now Egypt, were the first true anthropoids. Another group of Oligocene primates from Egypt, the *propliopithecids,* probably represent the first true apes.

Primate family tree The earliest known primates probably appeared about 65 million years ago, at the end of the Cretaceous Period and the beginning of the Paleocene Epoch. True monkeys and apes had evolved by the Oligocene Epoch. The earliest known members of the *hominid* family, to which human beings belong, may have developed during the late Miocene Epoch and the early Pliocene Epoch.

WORLD BOOK illustration

The earliest known members of the *hominid* family, to which human beings belong, may have developed about 5 million years ago, at the beginning of the Pliocene Epoch. Modern human beings evolved during the Pleistocene Epoch, which lasted from 2 million to 11,500 years ago.

People and nonhuman primates

The study of modern primates. *Primatologists,* the scientists who study nonhuman primates, have learned much about our closest relatives. Studies of great apes have revealed much about the evolution of our own species. Such studies have also disproved much of what we once believed about these animals. The work of the British primatologist Jane Goodall, for example, showed that chimpanzees use tools and engage in tribal warfare against other chimpanzees. Scientists once believed only people displayed such behaviors.

Some important primate research takes place in laboratories. For example, laboratory studies of the genetic makeup of chimpanzees have revealed how closely these primates are related to human beings. Other scientists are working to produce *clones,* or genetic copies, of monkeys. Such clones may prove useful in medical research.

Conservation. Today, nonhuman primates survive mostly in remote tropical areas that have little contact with human beings. Some of the most remote areas inhabited by primates remain unknown to modern science. Since 1990, in fact, scientists have discovered and described dozens of new primates in Madagascar, continental Africa, Southeast Asia, and Brazil.

But even while primatologists identify new species in the wild, the survival of many more primate species has become threatened. The chief threat to their survival is habitat destruction. Economic pressures in developing countries often drive people to cut down the rain forests for wood and for agriculture. Other human activities also endanger primates. Some of the most disturbing ways human beings threaten primate survival include the illegal trade in pets, the use of primate tissues in traditional medicine, and even the hunting of primates for food.

Some of the most endangered primates include our closest relatives, the great apes. The International Union for the Conservation of Nature and Natural Resources (IUCN) lists all the great apes as threatened or endangered. The mountain gorilla ranks as the most highly endangered, with only a few hundred individuals left in the Virunga Mountains of East Africa. In addition to habitat destruction and hunting, persistent political and economic instability in Africa and Asia further threaten the survival of our closest relatives. To continue learning about ourselves and our relationships to the natural world, human beings must take responsibility for preserving primates and their habitats. Randall L. Susman

Scientific classification. Primates make up the order Primates in the class Mammalia and the phylum Chordata.

Prime meridian. See Greenwich Meridian.

Prime minister heads the executive branch of government in countries with a parliamentary system. This leader is called a *chancellor* or *premier* in some countries. In most parliamentary systems, the prime minister leads the government in the formation of domestic and foreign policy and is the voice of the nation in international affairs. Canada, the United Kingdom, France, and many other countries have a prime minister. In France, however, a president manages foreign affairs.

The prime minister is officially appointed by the *head of state,* who is typically a monarch, governor general, or president. In most systems, the head of state has little choice of whom to appoint. The prime minister is normally the leader of the *majority party,* the party that holds most of the seats in the legislature. If no single party wins a majority of seats, two or more parties form a *coalition,* a grouping of parties that holds most of the seats in parliament. The leader of the coalition's chief party then becomes prime minister.

The prime minister names a *cabinet,* which consists of department heads called *ministers.* The ministers are responsible for making government policy. The membership of a coalition cabinet reflects the relative strengths of the parties in the coalition. In most systems, the ministers are members of parliament. Some systems require the prime minister to gain parliament's approval of the cabinet or its program.

The prime minister and the cabinet are responsible to the legislature and must resign if they lose a *vote of confidence.* In such a vote, the legislature decides whether to support a matter of importance to the prime minister's program. At any time, the prime minister may dissolve parliament—or have the head of state do so—and call new elections. Many parliamentary systems require a general election if one has not been held for a certain number of years.

Some political divisions within countries also have prime ministers. Canadian provinces, for example, have prime ministers called premiers. Gerald Benjamin

Prime minister of Canada is the leader of the Canadian national government. Queen Elizabeth II of the United Kingdom, who is also queen of Canada, is Canada's official head of state. The queen, on the recommendation of the prime minister, appoints the *governor general* as her representative in Canada. But the prime minister actually directs the government of Canada.

Canada has a parliamentary system of government. Under this system, the political makeup of the House of Commons, the lower house of Parliament, determines who serves as prime minister. The office traditionally goes to the leader of the party who can command a majority in the House. Almost every prime minister has been a member of the House. The exceptions were Sir John J. C. Abbott, who served in 1891 and 1892, and Sir Mackenzie Bowell, who served from 1894 to 1896. Both were members of the Canadian Senate.

The prime minister has three main duties. These duties are (1) to lead the governing party in Parliament, (2) to develop Canada's domestic and foreign policies, and (3) to direct, with the aid of the Cabinet, the government. The office of prime minister has no fixed term. However,

general elections are held at least every five years.

How the prime minister is chosen. Every party leader in Canada could someday become the prime minister. Party leaders are ordinarily chosen in conventions that resemble those held in the United States to nominate candidates for president and vice president.

A general election may be called for a variety of reasons. The prime minister must have the support of a majority of the House to remain in office. If the House passes a *vote of no confidence* in the prime minister's administration, the prime minister must then either resign or request that the governor general call a general election. The prime minister also may voluntarily request that an election be held in the hope of increasing the number of seats held by his or her party in the House or to test an issue.

The prime minister determines the date of a general election, and the election campaign lasts about eight weeks. If the party led by the prime minister again wins a majority in the House, he or she remains in office. If the party loses control of the House, the prime minister resigns. The leader of the largest party is offered the prime ministership by the governor general and is sworn into office. If a prime minister dies in office, the governor general appoints a successor, always on the advice of senior party figures.

Roles of the prime minister. The office and duties of the prime minister are not described in Canada's constitution but are based on those of the British prime minister. As the leader of the House of Commons, the prime

The prime ministers of Canada

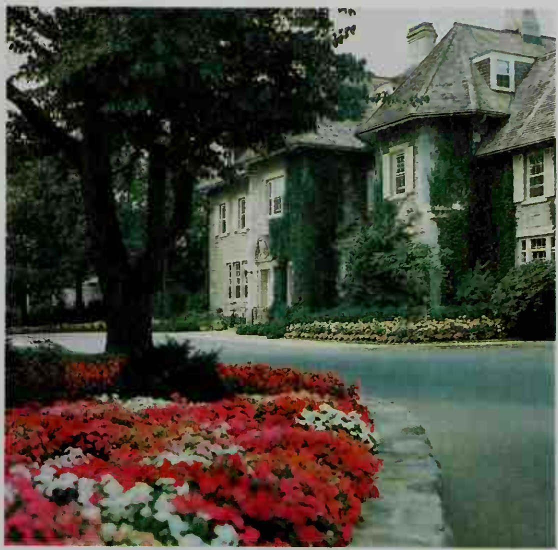
Each prime minister has a separate biography in *World Book*.

Facts in brief about the prime minister

Qualifications: The leader of any political party may become prime minister. Party leaders are chosen in political conventions and are usually members of the House of Commons. Candidates must be Canadian citizens.

How elected: The office of prime minister is normally assigned to the leader of the political party that has the most seats in the House of Commons. Seats in the House of Commons are determined by general elections. Election campaigns last about eight weeks.

Swearing in: The governor general formally appoints the prime minister and the prime minister's cabinet members at a swearing-in ceremony.



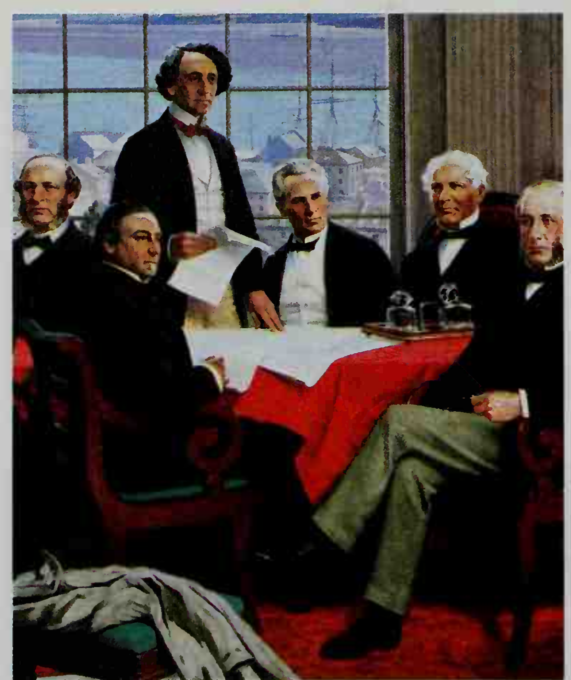
Term: The office of prime minister has no fixed term. General elections may be called for a variety of reasons. Elections are held at least every five years. Party leaders may serve as prime minister more than once.

Income: The prime minister receives an annual salary as a member of parliament, plus an additional amount for being prime minister. The prime minister lives in the official residence in Ottawa, Ontario.

Succession: If a prime minister dies, resigns, is disabled, or is removed from office, the governor general appoints a successor.

minister acts as the voice of the nation. He or she directs foreign policy, serves as the leader of the governing party, and, with the aid of a House leader, guides debates and discussions in the House.

By means of appointments to various offices, the prime minister shapes the character of the federal government. For example, the prime minister, through recommendations to the governor general, chooses Cabinet ministers, ambassadors, judges, military leaders, and other high government officials.



National Capital Commission. Ottawa, Canada

The prime minister's official residence overlooks the Ottawa River in Ottawa, Ontario. The house was completed in 1951 and is maintained by the Canadian government.

The prime minister lives in the official residence in Ottawa, Ontario. The house is maintained by the Canadian government.

History. Canada was headed by a British governor until the mid-1800's. Beginning in 1848, several colonies won a measure of self-government and chose their own premiers.

Detail of *Fathers of the Confederation* (1864), an oil painting on canvas by J. D. Kelly; Confederation Life Collection, Toronto, Canada

Canada's first prime minister was Sir John A. Macdonald, *standing.* He is shown at the Quebec Conference of 1864, which led to the formation of the Dominion of Canada in 1867.

Interesting facts about prime ministers

Who was Canada's first prime minister? Macdonald.
Who was the first French Canadian to serve as prime minister? Laurier.
Which prime minister served the most years? King, 21 years.
Who served the most years continuously as prime minister? Laurier, 15 years.
Which prime minister served the shortest term? Tupper, 10 weeks.
Which prime minister served the most nonconsecutive terms? King, 3.
Who was the first female prime minister? Campbell.
Which prime minister was the first Canadian to win the Nobel Peace Prize? Pearson.
Who was the oldest person to become prime minister? Tupper, 74.
Who was the youngest person to become prime minister? Clark, 39.
Which prime ministers died in office? Macdonald and Thompson.
Which prime minister married while in office? Trudeau.
Which prime ministers never married? Bennett and King.
Which prime minister was a former president of the United Nations General Assembly? Pearson.
Who was the first Liberal prime minister? Mackenzie.
Which prime ministers have the same birthdays? Macdonald and Chrétien, January 11.
Which prime minister was a physician? Tupper.
Who was the first prime minister born in what is now Canada? Abbott.

The Dominion of Canada was founded in 1867, and Sir John A. Macdonald became Canada's first prime minister. During his long time in office, Canada added the provinces of British Columbia, Manitoba, and Prince Edward Island, and the Northwest Territories. Alexander Mackenzie, who served from 1873 to 1878, established the Supreme Court of Canada in 1875.

Sir Wilfrid Laurier was the first French-speaking prime minister. Laurier held office from 1896 to 1911. The provinces of Alberta and Saskatchewan were created during this period. Laurier worked to unify the English-speaking and French-speaking people of Canada. Under Sir Robert L. Borden, who served from 1911 to 1920, the government fought World War I and imposed a military draft.

Canada became an independent power in international relations while W. L. Mackenzie King was prime minister. He served from 1921 to 1926, 1926 to 1930, and 1935 to 1948. Richard B. Bennett, who led the nation from 1930 to 1935, helped set up Canada's central bank and publicly owned radio broadcasting system.

Louis S. St. Laurent held office from 1948 to 1957 and played an important role in the establishment of the North Atlantic Treaty Organization (NATO). John G. Diefenbaker, the prime minister from 1957 to 1963, introduced Canada's first bill of rights. Lester B. Pearson, who served from 1963 to 1968, was a former diplomat and the first Canadian to win the Nobel Peace Prize. He received the award in 1957 for his achievements as an international statesman.

Pierre Trudeau, leader of the Liberal Party, became prime minister in 1968. Trudeau worked to improve relations between English- and French-speaking Canadians. Joe Clark of the Progressive Conservative Party succeeded him as prime minister in 1979. Trudeau became prime minister again in 1980 and resigned in 1984. He was succeeded by John Turner, another Liberal. The Progressive Conservatives won the national election of 1984, and Brian Mulroney became prime minister. Mulroney resigned in June 1993, and Kim Campbell, also a Progressive Conservative, became Canada's first woman prime minister. However, the Liberal Party won the national election held in October 1993, and Liberal leader Jean Chrétien succeeded Campbell as prime minister.

Primogeniture, *PRY muh JEHN uh chur,* is a system of inheritance widely used in Europe for hundreds of years. Under this system, the oldest child in a family, and often the oldest son, has the sole right to inherit land and other possessions from the parents. Primogeniture first developed under the feudal system (see **Feudalism**). In England and other countries, the oldest child in the royal family became the successor to the throne. The system kept the nobles' large landholdings from being broken up among their children into many small estates.

It also preserved the social position and prestige of the noble families. Peasants and other landholders also practiced primogeniture.

Primogeniture gradually disappeared in Europe, except among ruling families, as the feudal system died out. It came to an end in the United Kingdom in 1925, except for the royal family. The United States abolished primogeniture by law. Bryce Lyon

See also **Jefferson, Thomas** (Virginia lawmaker).

Primrose is the common name of a group of plants that usually flower in the early spring. Cultivated primroses are considered choice ornamental garden flowers. Many of these have been developed from the *common primrose,* which grows naturally in woods and meadows of Europe.

The common primrose has deeply veined leaves and yellowish-white flowers. Other varieties of primroses have flowers that range from yellow to pink, red, lilac, and purple. Some primroses make excellent potted plants for the window garden. Others are grown in greenhouses. The primrose is the flower for the month of February.

Primroses in the garden need shade and rich, moist loam. To start from seed, plant in February in a mixture of sand, loam, and leaf mold. The young plants should be set out in the open in May, placed in a permanent flower bed in September, and protected over winter. They will flower the following spring. Melinda F. Denton

Scientific classification. Primroses belong to the primrose family, Primulaceae. The scientific name for the common primrose is *Primula vulgaris.* Among the greenhouse and window varieties are the Chinese primrose, *P. sinensis,* and the Japanese, *P. japonica.*

Primrose, William (1904-1982), a Scottish violist, became known for his outstanding performances in solo concert. He made his debut at Albert Hall, London, in 1923. From 1930 to 1935, he toured Europe and the Americas as violist of the London String Quartet, and, later, as a solo violist. In 1937, he became a violist with the National Broadcasting Company Symphony Orchestra conducted by Arturo Toscanini, and later was soloist. In 1938, he founded his own quartet.

Primrose taught viola at the Curtis Institute of Music and the Juilliard School of Music. He was born in Glasgow, Scotland, on Aug. 23, 1904, and studied with Eugène Ysaÿe. Primrose died on May 1, 1982.
Stephen Clapp

Prince is a title of the highest rank of the nobility. The word comes from the Latin *princeps,* meaning *first. Princeps* was used as a title for civil and military officials among the ancient Romans. The German Visigoth and Lombard tribes that settled in the Roman Empire used *prince* to mean independent authority. The crusaders followed this practice when they set up governments in the Near East.

In modern times, the title *prince* or *princess* can be used in many ways. It is the title of the ruler of the principality of Liechtenstein. In the United Kingdom, only the eldest son of the ruler has a legal right to the title of prince, and only after the ruler has created him Prince of Wales. The oldest daughter may be granted the title Princess Royal. As a mark of courtesy, other members of the royal family, and they alone, are called prince or princess. In France, male members of the former royal Bourbon family are called prince. In Italy, the title is commonly used by the heads of many of the great Italian families. Joel T. Rosenthal

Prince Albert (pop. 34,291), is an important center of commercial trading and of tourism in central Saskatchewan. It lies on the North Saskatchewan River near the Prince Albert National Park (see **Saskatchewan** [political map]). The city's industries include bottling; welding and fabricating; and the manufacture of pulp and paper, and infrared heating pads. Regional airlines connect Prince Albert to Saskatoon and Regina, Saskatchewan.

Prince Albert was founded in 1866 and incorporated as a city in 1904. It has a mayor-council form of government. Wayne J. Roznowsky

Prince Albert National Park. See **Canada** (National park system).

Prince consort is the husband of a reigning queen. In countries where the daughter of a king may inherit the throne, her husband does not have the title of king. Denmark, the Netherlands, and the United Kingdom are among the countries that allow a woman to rule.

Barrett & MacKay, Masterfile

Prince Edward Island

Prince Edward Island is the smallest but most thickly populated province of Canada. Its people usually call their province "The Island" or simply use its initials, "P.E.I." The people live in small, scattered communities. But the average number of people to the square mile or square kilometer is greater than in any other province. Charlottetown is the capital and largest city of Prince Edward Island.

Prince Edward Island is the only Canadian province that is entirely separated from the North American mainland. The island lies in the Gulf of St. Lawrence, a rich fishing area off the Atlantic coast of Canada. Lobsters are the most valuable catch of the island's fishing industry. The province's oysters are known for their delicious flavor. Fishing crews from the island also catch cod, crabs, flounder, hake, herring, mackerel, scallops, and tuna.

The chief sources of employment and income for the people of the island are the service industries. Spending by tourists benefits such service industries as transportation and retail trade. Agriculture is also an important economic activity in the province. The island's fertile soil is its greatest natural resource, and farms cover nearly half of the province. Each year, Prince Edward Island produces large numbers of potatoes, its chief crop. Other important farm products include beef cattle, blueberries, hogs, and milk.

The island lacks valuable minerals and cheap sources of power. In addition, transportation to and from the mainland is expensive. For these reasons, manufacturing on Prince Edward Island has developed slowly. Food processing is the leading manufacturing activity. The production of aircraft parts is also important.

Prince Edward Island has long stretches of red or white sandy beaches along its coasts, with warm currents offshore. Few people live far from a good beach.

The island's streams are well stocked with fish. Many

The contributors of this article are Harry Baglole, Director of the Institute of Island Studies at the University of Prince Edward Island; and David Weale, Professor of History at the University of Prince Edward Island.

Barrett & MacKay

Charlottetown, the province's capital

people enjoy sailing, surfing, and fishing off the coasts of the province. The island also has many fine golf courses. All of these attractions bring hundreds of thousands of vacationers to Prince Edward Island every year.

Micmac Indians lived on what is now Prince Edward Island long before white people arrived. The Indians called the island *Abegweit* (cradled on the waves). A Micmac legend tells how the god Glooscap finished painting the beauties of the world. Then he dipped his brush into a mixture of all the colors and created Abegweit, his favorite island.

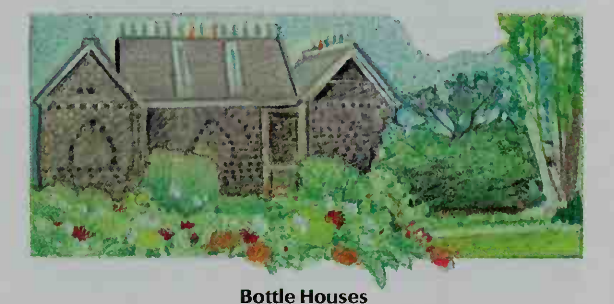
The British named the island in honor of a son of King George III. Prince Edward Island's fertile red soil and its location in the Gulf of St. Lawrence have given it two nicknames—the *Garden of the Gulf* and the *Million Acre Farm.* In addition, it is often called *Spud Island* because of its large potato production.

Prince Edward Island is one of the Atlantic Provinces. For its relationship to the other Canadian provinces, see the articles on **Atlantic provinces; Canada; Canada, Government of; Canada, History of.**

Interesting facts about Prince Edward Island

WORLD BOOK illustrations by Kevin Chadwick

Irish moss, Canada's most valuable commercial seaweed, is harvested off the coast of Prince Edward Island. The island exports about 6,000 tons (5,400 metric tons) of Irish moss each year to manufacturers throughout the world. The manufacturers extract a substance called *carrageenin* from the moss. Carrageenin is a thickening agent used in cosmetics and in food products such as ice cream, pudding, and cake mixes.



Irish moss

The meeting of the tides is a unique sight that can be observed from North Cape, the northernmost point of the province. There the tides of the Northumberland Strait overlap with those of the Gulf of St. Lawrence. The phenomenon is especially evident at high tide, but the line where the two tides meet is visible throughout the day.

The Bottle Houses at Cape Egmont, built between 1980 and 1983, are houses made from many kinds of bottles. The largest of the three houses measures 18 feet by 24 feet (5.5 meters by 7.3 meters) and is made from 12,000 bottles.

Prince Edward Island in brief

Symbols of Prince Edward Island

The provincial flag, adopted in 1964, bears an adaptation of the coat of arms. On the coat of arms, adopted in 1905, the British lion symbolizes the province's ties with the United Kingdom. Three oak saplings represent the three counties of Prince Edward Island. The large oak tree stands for the United Kingdom.

Provincial flag

Prince Edward Island (brown) ranks as the smallest of all the provinces. It is one of the Atlantic Provinces (yellow).

Province House is in Charlottetown, the capital of Prince Edward Island since 1768.

General information

Entered the Dominion: July 1, 1873, the 7th province.
Provincial abbreviation: PE (postal).
Provincial motto: *Parva Sub Ingenti* (The Small Under the Protection of the Great).
Provincial song: "The Island Hymn." Words by Lucy Maud Montgomery; music by Lawrence W. Watson.

Land and climate

Area: 2,185 mi^2 (5,660 km^2).
Elevation: *Highest*—465 ft (142 m) above sea level in Queens County. *Lowest*—sea level.
Coastline: 688 mi (1,107 km).
Record high temperature: 98 °F (37 °C) at Charlottetown on Aug. 19, 1935.
Record low temperature: −35 °F (−37 °C) at Kilmahumaig, near Alberton, on Jan. 26, 1884.
Average July temperature: 66 °F (19 °C).
Average January temperature: 19 °F (−7 °C).
Average yearly precipitation: 44 in (111 cm).

Important dates

- **1534** Jacques Cartier, a French explorer, landed on Prince Edward Island.
- **1603** Samuel de Champlain claimed the island for France and named it Île St. Jean.
- **1763** Britain acquired the island from France in the Treaty of Paris and changed its name to St. John's Island.
- **1769** St. John's Island, which had been part of Nova Scotia, became a separate British colony.

Sources of information

For information on tourism in Prince Edward Island, write to: Prince Edward Island Department of Tourism, P.O. Box 2000, Charlottetown, PE C1A 7N8. The Web site at www.gov.pe.ca/visitorsguide is also a good source of tourist information. For information on the province's economy, write to: Provincial Treasury, P.O. Box 2000, Charlottetown, PE C1A 7N8. The treasury's Web site at www.gov.pe.ca/pt is also useful. For information on the government and history of Prince Edward Island, write to: Island Information Service, P.O. Box 2000, Charlottetown, PE C1A 7N8. The government's Web site at www.gov.pe.ca also provides a helpful gateway to information on the island's government and history.

1799 The colony was renamed Prince Edward Island.

1864 The first Confederation Conference was held in Charlottetown to discuss a federal union.

1873 Prince Edward Island became the seventh province on July 1.

1997 Confederation Bridge, which connects Prince Edward Island and the Canadian mainland, was completed.

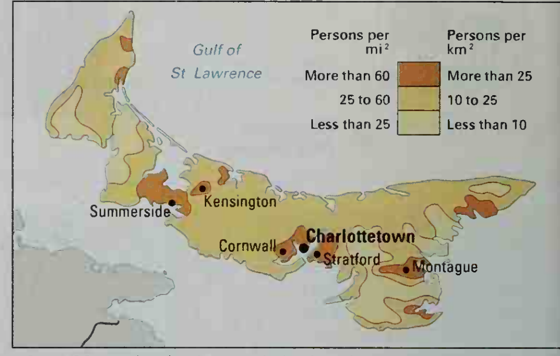
People

Population. The 2001 Canadian census reported that Prince Edward Island had 135,294 people. The population of the province had increased by less than 1 percent over the 1996 figure of 134,557.

About 45 percent of Prince Edward Island's people live in urban areas. About 40 percent live in Charlottetown and its surrounding area. Summerside is the province's only other city. The province has about 50 incorporated towns and villages, each of which has fewer than 10,000 people. See **Charlottetown; Borden.**

Almost all the province's people were born in Canada. About three-fourths of the people have some British or Irish ancestry, and nearly all the islanders speak English. About one-fourth of the island's people have some French or Acadian ancestry. French is spoken in a few small communities, especially in the Evangeline region in the western part of the province. About 400 Micmac Indians live on reservations in the province.

Schools. The first schools on the island were established during the early 1800's. In 1852, the Free Education Act created a property tax to provide funds for school costs. The province established a Central Board of Education in 1877 and a Department of Education in 1945. The minister of education is the head of the department.



Today, provincial law provides for free public education for all children from ages 6 to 20 until the completion of high school. However, a child may attend a private school or may be educated at home with the approval of the provincial minister of education. Most schools offer instruction in English, but some offer instruction in French. For the number of students and teachers on Prince Edward Island, see **Education** (table).

The province has one university, the University of Prince Edward Island in Charlottetown. The school was established in 1969. In that year, the faculties and students of St. Dunstan's University, founded in 1855, and Prince of Wales College, founded in 1834, joined to become the new University of Prince Edward Island. The Atlantic Veterinary College is on the university's campus. Holland College, a public community college, has locations throughout the province. It offers post-secondary and adult education programs in a variety of fields.

Libraries and museums. In 1933, Prince Edward Island established Canada's first provincial library system. The Confederation Centre of the Arts, which was opened in Charlottetown in 1964, includes an art gallery, theaters, and a public library. The province has many branch libraries and community historical museums.

Population density

Prince Edward Island has fewer people than any other Canadian province, but because of its small size it is the most densely populated province. Charlottetown is the capital.

Over a million vacationers visit Prince Edward Island each summer. Many visitors camp or go swimming, sailing, kayaking, or deep-sea fishing in the warm coastal waters. People go trout fishing or canoeing in inland streams. Hikers and bicyclists travel across the island along the Confederation Trail. Golfing is also popular.

Several annual events take place in the summer. The Charlottetown Festival runs from June to October. The highlight of this theatrical festival is the musical play *Anne of Green Gables,* based on the book by the Prince Edward Island novelist Lucy Maud Montgomery. Harness racing is featured at the Charlottetown Driving Park and the Summerside Raceway. Country style lobster suppers are served daily in several communities.

Places to visit

Following are brief descriptions of some of Prince Edward Island's many interesting places to visit:

Basin Head Fisheries Museum, near Souris, captures the history of the island's fishing industry with artifacts and photographs. A boardwalk provides access to the nearby white-sand Basin Head beach.

Confederation Centre of the Arts, in Charlottetown, was built in 1964 to commemorate the 100th anniversary of the meeting of the Fathers of Confederation. It has an art gallery/museum, a library, memorial hall, theaters, a restaurant, and a gift shop.

Harbourfront Jubilee Theatre, on Summerside's scenic waterfront, features dramatic and musical theater productions and renowned touring artists.

Lennox Island, in Malpeque Bay, is a Micmac Indian reservation.

Orwell Corner Historic Village, in Orwell, is a reproduction of a small agricultural community of the 1890's. The village also hosts a number of recreational and musical events throughout the summer and fall.

P.E.I. Preserve Co., in New Glasgow, lets visitors view the manufacture of preserves and a variety of food specialty items.

Woodleigh Replicas and Gardens, near Burlington, has many reproductions of British castles, churches, and homes.

National parks and sites. Prince Edward Island National Park includes the house that served as the setting of the story *Anne of Green Gables.* Every year, thousands of people visit this house. The park also includes a spectacular dune system on Greenwich, a peninsula that separates St. Peters Bay from the Gulf of St. Lawrence. See **Canada** (National parks).

Fort Amherst-Port La Joye National Historic Site, near Charlottetown, is the site of a British fort built in 1758 and an earlier French settlement. It includes a small historical museum.

Province House National Historic Site in Charlottetown includes the Confederation Chamber. This room, called the *Birthplace of Canada,* is furnished as it was in 1864 when the Fathers of Confederation planned the union of Canada there.

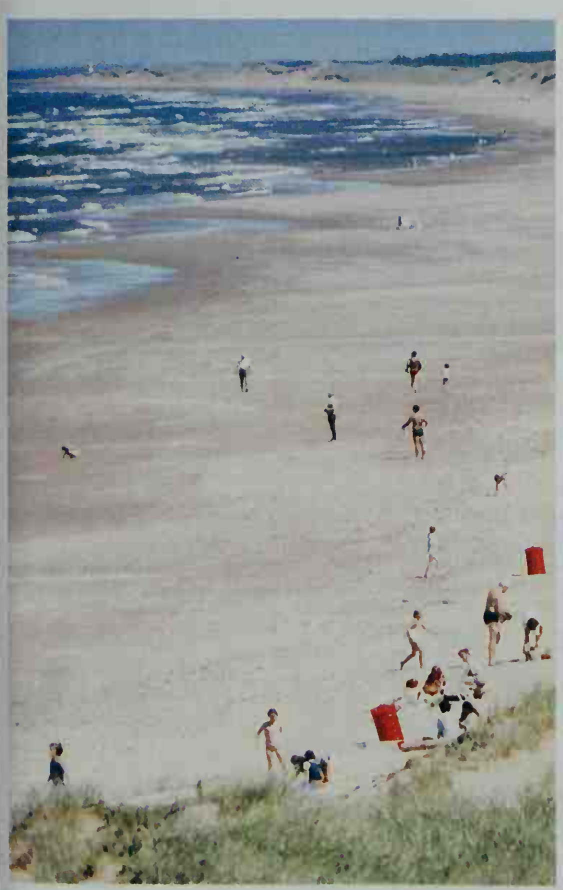
Provincial parks. Prince Edward Island established its park system in 1958. Today, it has about 30 provincial parks. Many of them have native birds, flowers, or marine life. Some have hiking trails. For information on any of the provincial parks, write to Visitor Services, P.O. Box 940, Charlottetown, PEI C1A 7M5. The Web site at www.gov.pe.ca/visitorsguide/explore/parks also provides information on the island's provincial parks.

Annual events

May
Ceili at the Irish Hall in Charlottetown; Indoor Scottish Ceilidh Concert in Richmond (May-October).

June
Summerside Highland Gathering; Bridgefest in Borden-Carleton; Charlottetown Festival (June-October).

July
Festival of Lights in Charlottetown; Street Rod Show 'n' Shine in Montague; Souris Regatta; Summerside Lobster Carnival; Potato Blossom Festival in O'Leary; Northumberland Provincial Fisheries Festival in Murray River; Crapaud Exhibition; Charlottetown Race Week; Ceilidhs (traditional Scottish gatherings) in Orwell (July and August); Victoria Playhouse Summer Festival (July to September); Larry Gorman Folk Festival in Tyne Valley (late July or early August).



August
Tyne Valley Oyster Festival (early August); Fête Nationale des Acadiens in Abrams Village; Community Harvest Festival in Kensington; Plowing Match and Agricultural Fair in Dundas; Highland Games and Gathering of the Clans in Eldon; Old Home Week Provincial Exhibition in Charlottetown; Festival of the Fathers in Charlottetown; Lucy Maud Montgomery Festival in Cavendish and area.

September
Acadian Festival and Agricultural Exhibition in Abrams Village (early September); Prince Edward Island International Shellfish Festival in Charlottetown; Cornwall Cornfest; Trailfest (island-wide); and the Prince Edward Island Studio Tour.

Land and climate

Almost all the land of Prince Edward Island is a gently rolling plain. Forests cover about half the island. The province also has meadowland. The highest point rises 465 feet (142 meters) above sea level in Queens County. Many tidal inlets (called *rivers* locally) and deep bays indent the 688-mile (1,107-kilometer) coastline. Two of the bays, Hillsborough and Malpeque, nearly cut the island into three parts. Other major bodies of water along the island's shores include Bedeque, Cardigan, and Egmont bays. Low cliffs rise along the eastern and southern coasts. Lennox Island and several other small islands that belong to the province lie near the shores.

Northern grasses and wildflowers, such as black-eyed Susans, buttercups, daisies, and violets, thrive in the red soil of the island. About half of the land is used for farming. Small wood lots of beech, birch, evergreen, and maple trees dot the land. Wild orchards of apple and cherry trees grow in some areas.

The island has small game animals such as ducks, geese, Hungarian partridges, ring-necked pheasants,

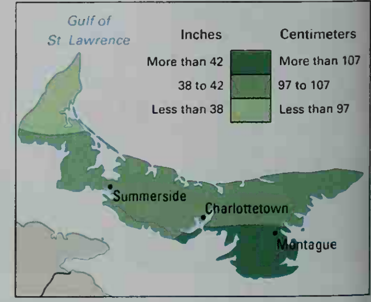
Average January temperatures

Winter temperatures are mostly even throughout the island. The southeast is slightly warmer.



Average July temperatures

Summers are mild throughout Prince Edward Island. The northeastern corner is slightly cooler than the rest of the island.

Average yearly precipitation

There is only a small difference in precipitation throughout Prince Edward Island. The southeast is the wettest section.

WORLD BOOK maps; based on the *National Atlas of Canada.*

Wildflowers thrive in the red soil of Prince Edward Island. This brightly colored field of lupines is in the southeastern part of the province.

ruffled grouse, and snowshoe hares. Coyotes, foxes, raccoons, and skunks are also common. Game fishes include Atlantic salmon and several kinds of trout. Clams, cod, crabs, hake, herring, lobsters, mackerel, mussels, oysters, and scallops live in the offshore waters.

The island has a milder climate than that of Canada's mainland. The province has an average temperature of 19 °F (−7 °C) in January and 66 °F (19 °C) in July. Kilmahumaig, near Alberton, had the lowest temperature, −35 °F (−37 °C), ever recorded in the province, on Jan. 26, 1884. Charlottetown had the highest temperature, 98 °F (37 °C), on Aug. 19, 1935. The province has an average *precipitation* (rain, melted snow, and other forms of moisture) of 44 inches (111 centimeters) and an average snowfall of 109 inches (276 centimeters) per year.

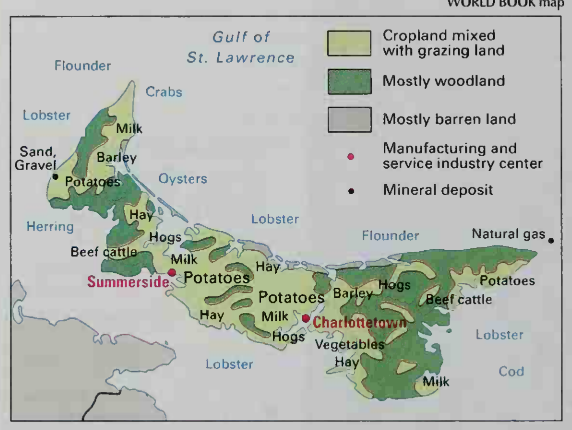
Economy

Service establishments such as hotels, restaurants, and shops receive much income from the hundreds of thousands of tourists who visit Prince Edward Island each year. Manufacturing activities also employ many workers in the province. Farming and fishing have retained much of their traditional importance to Prince Edward Island's economy.

Natural resources. Rich red soil is the province's chief resource. This *loam* (mixture of clay, decayed matter, and sand) lies on beds of soft red or brown sandstones and shales. The loss of topsoil due to erosion is a serious problem on the island. Sand and gravel are the most valuable mined products on the island. Deposits of natural gas, uranium, and gold also have been found. The water supply comes mainly from wells.

Service industries account for the largest portion of Prince Edward Island's *gross domestic product* (GDP)—that is, the total value of all goods and services produced in the province in a year. The most important group of service industries is made up of community, business, and personal services. This group includes such services as education, health care, and the operation of hotels, resorts, and restaurants.



Finance, insurance, and real estate form the province's second-leading service industry group. The increasing popularity of Prince Edward Island as a site for vacation homes and resorts has led to rapid growth in real estate businesses.

Other service industries are government; wholesale and retail trade; and transportation and communication. The federal government provides large amounts of financial assistance to the people of Prince Edward Island

Economy of Prince Edward Island

This map shows the economic uses of land in Prince Edward Island and where the province's leading farm and mineral products are produced. Manufacturing centers are shown in red.

WORLD BOOK map

compared with most other provinces.

Agriculture. Farmland makes up almost half of Prince Edward Island's land area, a greater share than in any other province except Saskatchewan. The island has about 2,000 farms.

Potatoes, grown for table use and for seed, are the chief crop of Prince Edward Island. More than half of the potato crop is made into French fries at local processing plants. The province also ships many potatoes off the island, mainly to Ontario, Quebec, and the United States.

Other important crops on Prince Edward Island include barley, blueberries, and vegetables. Broad fields produce hay for the dairy industry. Livestock includes beef and dairy cattle and hogs.

Manufacturing. Goods manufactured on the island have a *value added by manufacture* of about 275 million Canadian dollars a year. This figure represents the difference between the value of raw materials and the value of finished products made from the raw materials. The processing of farm and fish products accounts for most of the province's manufacturing income. The manufacture of aircraft parts also has become a major activity. Companies in the province also produce printed materials, wood products, fabricated metal products, fertilizer, and medical instruments.

Fishing industry. Lobsters are by far Prince Edward Island's most important catch. Other catches include cod, crab, flounder, herring, and oysters. About 90 percent of the total catch is exported. More than half of all cultivated mussels produced in North America come from Prince Edward Island. Irish moss, a valuable commercial seaweed, is harvested off the island's coast.

Transportation and energy. Confederation Bridge and a ferryboat line carry passengers and motor vehicles across Northumberland Strait between Prince Edward Island and the Canadian mainland. A second ferryboat line operates between Souris and the Magdalen Islands, a part of Quebec in the Gulf of St. Lawrence. Sheltered bays provide good harbors at Charlottetown, Georgetown, Souris, and Summerside. Icebreakers help keep them open to shipping the year around.

Airlines provide service between Charlottetown and major cities in eastern and central Canada. A fine highway system links the province's largest urban areas. All railroad service on Prince Edward Island was discontinued in the late 1980's.

The island lacks cheap sources of power. It imports nearly all its electric power from New Brunswick through a cable under Northumberland Strait.

Communication. The province has two daily newspapers. *The Guardian* was founded in Charlottetown in 1887. *The Journal-Pioneer* was established in Summerside in 1865. Eight radio stations serve the province. Station CFCY, the first one on the island, began broadcasting from Charlottetown in 1924. Cable television systems and Internet providers serve many communities.

Production and workers by economic activities

Economic activities	Percent of GDP* produced	Employed workers: Number of people	Employed workers: Percent of total

Government

Lieutenant governor of Prince Edward Island represents Queen Elizabeth II of the United Kingdom in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The position of lieutenant governor is essentially an honorary one.

Premier of Prince Edward Island is the actual head of the provincial government. Like the other provinces and Canada itself, Prince Edward Island has a parliamentary form of government. The premier is an elected member of the Legislative Assembly and is usually the leader of the Assembly's majority party. The premier presides over the Executive Council (cabinet). This council includes the premier and a number of ministers appointed by the premier from among his or her party's members in the Legislative Assembly. The council resigns if it loses the support of a majority of the Assembly.

Legislative Assembly is a one-house legislature that makes the provincial laws. It has 27 members, who are elected from 27 electoral districts. The members of the Legislative Assembly are elected to terms that may last

up to five years. However, the lieutenant governor, on the advice of the province's premier, may call for an election sooner.

Courts. The highest court on Prince Edward Island is the Supreme Court. The Supreme Court is made up of nine justices, including a chief justice. These justices are appointed by the governor general in council of Canada. They serve until the age of 75.

Local government. Charlottetown and Summerside, the province's only cities, and most of the towns have a mayor-council form of government. Most smaller communities are governed by community councils.

Revenue. Taxes levied by the provincial government account for more than half of its income. The most important are a general sales tax and a gasoline tax.

The rest of the province's income comes from federal-provincial tax-sharing arrangements and federal grants. License fees and governmental liquor sales are other sources of income.

Politics. Prince Edward Island has three political parties—the Liberal Party; the New Democratic Party; and the Progressive Conservative Party, usually called simply the Conservative Party. The Liberals have controlled more than half the administrations of the province.

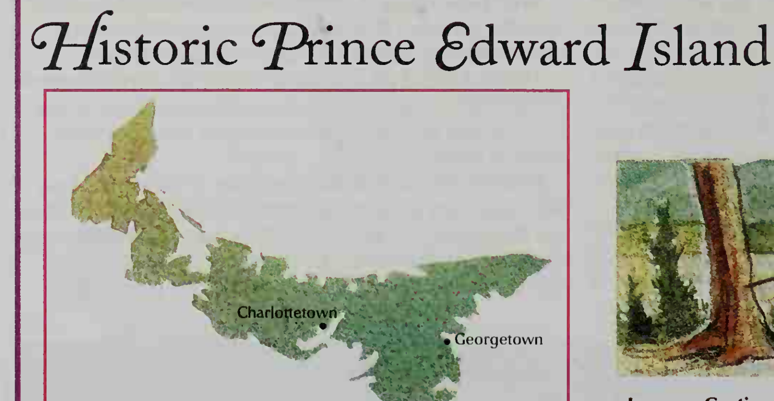
History

Exploration and early history. The Indians of what is now Prince Edward Island belonged to the Micmac tribe. Vikings may have visited the island around A.D. 1000. Basque fishing crews from Europe landed there in the early 1500's. The French explorer Jacques Cartier landed on the island on June 30, 1534. Another French explorer, Samuel de Champlain, claimed the island for France in 1603. He named it *Ile St. Jean* (Isle St. John). The island became part of the French colony of Acadia.

French people began to settle on the island in 1720. British troops took over the area in 1758, during the French and Indian War (1754-1763). They deported most of the French Acadians to France. In the Treaty of Paris of 1763, France gave the island to Britain (now the United Kingdom). The British changed its name to St. John's Island and made it a part of Nova Scotia.

In 1765, the colony was divided into 67 townships. In 1767, these townships were given away in a lottery to British nobles, military officers, and government officials. The British depended on these landlords to develop the area. Few of the landlords kept their promises to improve their property, and the landownership question led to bitter political disputes. In 1769, St. John's Island became a separate British colony. The British changed its name to Prince Edward Island in 1799.

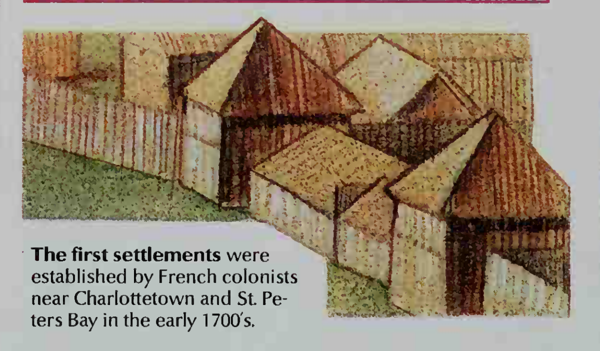
Self-government. The British gave the islanders control of their local affairs in 1851. In 1864, delegates from Prince Edward Island, New Brunswick, and Nova Scotia met in Charlottetown to discuss forming a *Maritime union* (union of these Maritime colonies). Delegates from present-day Ontario and Quebec joined them and proposed a federal union of all the provinces. The delegates met again later in 1864 in Quebec. This conference drew up a plan for Canadian union that led to the creation of the Dominion of Canada on July 1, 1867.



Prince Edward Island refused to join the Dominion. The people were enjoying a period of great economic prosperity and did not feel they needed union. In addition, they feared that the larger provinces would control their small island in the new government.

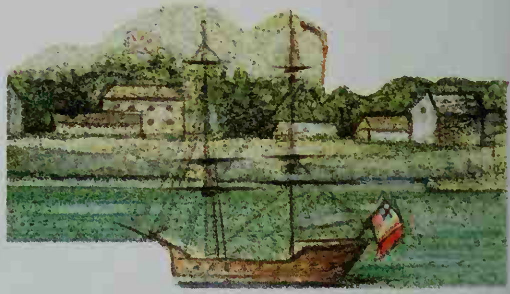
Member of the union. In the early 1870's, the Prince Edward Island Railway was built. As a result, the island fell into debt, and the people realized they needed help. On July 1, 1873, Prince Edward Island entered the Dominion as the seventh province. James C. Pope, a Conservative who was born on the island, became the first provincial premier in the confederation.

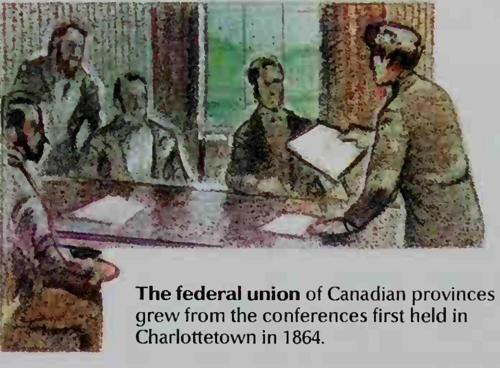
The problem of absentee landownership continued until the provincial government passed the Land Purchase Act of 1875. This act forced many landlords to sell their property and gave the province funds to buy the property. The people bought the land from the province and improved their own farms.



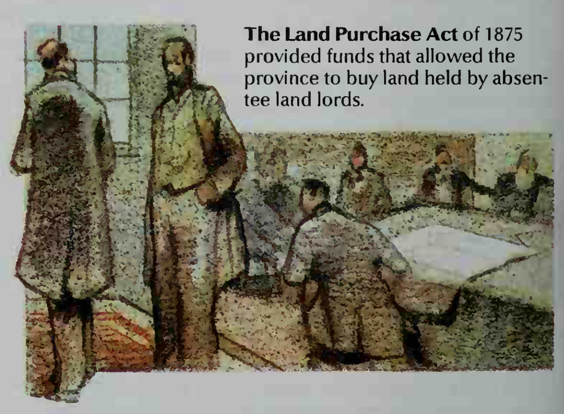
During the late 1800's, the province's small local industries could not compete with the larger industries in central Canada, and the island's economy declined.

Historic Prince Edward Island





Jacques Cartier, a French explorer, landed on what is now Prince Edward Island in 1534.



The first settlements were established by French colonists near Charlottetown and St. Peters Bay in the early 1700's.

The British obtained the island from France by the Treaty of Paris in 1763.

The federal union of Canadian provinces grew from the conferences first held in Charlottetown in 1864.

The Land Purchase Act of 1875 provided funds that allowed the province to buy land held by absentee land lords.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Prince Edward Island

1534 The French explorer Jacques Cartier landed on what is now Prince Edward Island.

1603 The French explorer Samuel de Champlain claimed the island for France and named it Ile St. Jean.

1720 France established settlements near present-day Charlottetown and St. Peters Bay.

1758 British troops took over the island during the French and Indian War.

1763 France ceded the island to Britain in the Treaty of Paris. Britain renamed the area St. John's Island and annexed it to Nova Scotia.

1769 The island became a separate British colony.

1799 The colony was renamed Prince Edward Island.

1851 The colony was granted self-government.

1864 The first Confederation Conference was held in Charlottetown to discuss a federal union.

1873 The island entered the Dominion of Canada on July 1.

1875 Absentee landownership on the island was ended.

1890's Thousands of islanders began moving to the mainland in search of greater job opportunities.

1984 An economic development program, which began in 1969, was completed.

1993 Catherine Callbeck became the premier of Prince Edward Island. She was the first woman in Canada to gain a provincial premiership by leading her party to victory in a general election.

1997 Confederation Bridge, which connects Prince Edward Island and the Canadian mainland, opened.

Prince Edward Island's limited income from taxes decreased as the population grew smaller, and the island became more dependent on federal aid. Thousands of islanders moved away. They sought greater job opportunities elsewhere in Canada and the United States.

During the 1920's and 1930's, the province expanded such governmental services as education, health and welfare, and public works. The high costs of these services increased the province's financial problems.

The mid-1900's. The 1941 census showed the first population increase on Prince Edward Island since 1891. During the 1940's, the province received large increases in federal aid, which helped pave many of the island's red clay roads. The improved highways in the province speeded delivery of farm and fishery products to markets, increased contact between urban and rural areas, and made school consolidation possible.

Economic development. A federally supported economic development plan, begun in 1969, was concluded in 1984. This plan provided for new schools and highways, opened new markets for farm and fish products, and expanded the tourism industry. It also helped attract some small manufacturing companies to the province. But manufacturing remains limited. The province continues to rely on the service industries—especially tourism—and on agricultural production. The island is also still heavily dependent on federal economic aid. Prince Edward Island has one of the lowest provincial and *per capita* (per person) incomes in all of Canada. But the island's residents are working to create a stable economy that will enable people in both rural districts and small communities to make a comfortable living.

Recent developments. In 1993, construction began on a bridge to connect Prince Edward Island and New Brunswick across Northumberland Strait. The bridge, called Confederation Bridge, was completed in 1997.

In January 1993, the Liberal Party chose Catherine Callbeck to succeed Joseph Ghiz as party leader and premier of Prince Edward Island. The Liberals won the general election held in March, making Callbeck the first woman in Canadian history to become a provincial premier by leading her party to victory in a general election. Callbeck resigned as party leader and premier in 1996. Keith Milligan succeeded her in both positions. The Progressive Conservatives won a general election in November. Patrick G. Binns, the Conservative leader, then became premier. Harry Baglole and David Weale

Prince George (pop. 72,406) is an industrial city in the Canadian province of British Columbia. The city lies near

© Canfor Corporation

Prince George, an industrial city in British Columbia, is a center for pulp and paper manufacturing. Pulp mills such as the one shown above have stimulated the city's growth.

the center of British Columbia, at the junction of the Fraser and Nechako rivers (see **British Columbia** [political map]). The leading industries in the city manufacture chemicals, lumber products, petroleum products, and pulp and paper. Mines in the area produce coal, copper, mercury, and molybdenum. Prince George is the home of the University of Northern British Columbia.

Carrier Indians lived in the Prince George area before whites arrived in the early 1800's. Simon Fraser, who worked for the North West Company, a fur-trading firm, founded a trading post there in 1807. He named it Fort George after King George III of the United Kingdom.

Fort George grew quickly after the Grand Trunk Pacific Railway began to serve the area in 1914. It was renamed Prince George and incorporated in 1915. Prince George grew rapidly during the 1960's, when three pulp mills opened in the area. Prince George has a mayor-council form of government. Roy K. Nagel

For the monthly weather in Prince George, see **British Columbia** (Climate).

Prince of Wales is the title given to the first male heir to the British throne. He is always the oldest son of the sovereign, unless that son has died or given up the title. Edward I, the English king who conquered Wales in 1282 and 1283, defeated and killed the last Welsh Prince of Wales. In 1301, he gave the title to his oldest son. Later, this son became king as Edward II. Since the reign of Edward II, almost all the oldest male heirs to the British throne have received it.

The title *Prince of Wales* is purely honorary. Sons of British monarchs do not inherit the title. It is newly created for each prince. The monarch's oldest son becomes *Duke of Cornwall.* Even after he is named Prince of Wales, he receives his income from the Duchy of Cornwall, not from Wales. Queen Elizabeth II's son, Prince Charles, became Duke of Cornwall when his mother took the throne in 1952. His mother named him Prince of Wales in 1958 and officially presented him to the Welsh people in 1969. Ralph A. Griffiths

Prince Rupert, British Columbia (pop. 14,643), is the second largest port on Canada's west coast. Only Vancouver is larger. The city lies on Kaien Island, north of the mouth of the Skeena River. For location, see **British Columbia** (political map). A bridge links the city to the mainland. Prince Rupert is a fishing, logging, and pulp-producing center. The city has the world's largest salmon cannery. It also has the world's largest cleaning grain elevator, a facility that removes foreign material from grain before storing it. A coal terminal opened in Prince Rupert in 1984. The city has a mayor-council form of government. Daniel Gilmore

Prince Rupert, in British Columbia, is the second largest port on Canada's west coast. Only Vancouver is larger. Prince Rupert lies on Kaien Island, north of the mouth of the Skeena River. Boating is a popular pastime among the city's residents.

Mahlon Lovett, Princeton University

Princeton University, founded in 1746, is one of the oldest institutions of higher learning in the United States. The courtyard outside McCosh Hall, *shown here,* is a popular meeting place.

tional Convention studied at Princeton. Presidents James Madison and Woodrow Wilson graduated from Princeton. Wilson also headed Princeton from 1902 to 1910. Vice Presidents Aaron Burr and George M. Dallas and several Cabinet members and justices of the Supreme Court of the United States were also graduates.

Campus buildings. The campus includes over 150 buildings, not counting residences for faculty and staff. Nassau Hall, completed in 1756, is the oldest building. It was occupied by British and colonial forces during the Revolutionary War in America. General George Washington captured the building on Jan. 3, 1777, to end the Battle of Princeton, a turning point in the war. Nassau Hall was the national capitol for four months in 1783, when the Congress of the Confederation met there.

The university library includes many specialized libraries and has collections that range from Egyptian papyri and Babylonian cylinder seals to the papers of American author F. Scott Fitzgerald. The Plasma Physics Laboratory is on the James Forrestal campus, about 3 miles (5 kilometers) from the main campus. Other laboratories there include the Geophysical Fluid Dynamics Laboratory and the Daniel and Florence Guggenheim Laboratories for the Aerospace Propulsion Sciences.

Educational program. Princeton has 33 departments and 23 interdepartmental programs. The undergraduate plan of study includes the preceptorial method, which brings teacher and student together and fosters individualism. The four-course plan of study encourages self-education. Students acquire broad knowledge in their underclass years. In their upperclass years, they engage in a specific field or interdepartmental program. The graduate school offers courses in architecture, engineering and applied science, liberal arts and sciences, and international affairs. The Woodrow Wilson School prepares students for careers in public service.

History. Princeton University was founded in 1746 as a college for men called the College of New Jersey. It was originally sponsored by the Presbyterian Church, but it was one of the first colleges in the United States to admit students of all faiths. The first classes were held in 1747 in Elizabeth, New Jersey. The college moved to Newark in 1748, and to Princeton in 1756. It was renamed Princeton University in 1896. In 1969, Princeton became coeducational.

During the 1960's and 1970's, the university built an architecture hall, a computer center, a manuscript library, a center for music, and dormitories. The Tokamak Fusion Test Reactor at the Plasma Physics Laboratory opened in 1982 and operated until 1997. A new fusion device called the National Spherical Torus Experiment opened in 1999. Critically reviewed by Princeton University

Príncipe Island. See **São Tomé and Príncipe.**

Print. See **Engraving; Japanese print; Percale; Photography** (Developing and printing); **Printing.**

Printer is a device used to print text and illustrations created using a computer. There are three main types of printers: (1) laser printers, (2) inkjet printers, and (3) impact printers. Each type of printer responds to instructions from software in the computer.

Laser printers use a process adapted from photocopying machines. A tiny, precise laser electrically charges portions of a light-sensitive metal drum, duplicating on its surface the text or images created on the computer. Dry ink called *toner* is oppositely charged and dusted onto the drum. The toner sticks only to the charged parts of the drum. Paper is given an electrical charge matching that on the charged portions of the drum but stronger. The paper is then pressed against the drum, and the toner is attracted to the paper. The paper passes through rollers that heat it for an instant, causing the toner to adhere permanently to the paper.

Laser printers can produce several pages of text per minute. They reproduce complex images and photographs more slowly. Some can produce color output. Some laser printers also can approach the print quality standards of traditional printing presses. Laser printers have revolutionized the printing and design industries and made possible *desktop publishing* (the use of personal computers to design and edit publications). See **Computer** (picture: Parts of a laser printer)

Inkjet printers use a high-speed nozzle to spray a jet of ink onto paper in a pattern that matches the text or images created on the computer. See **Inkjet printer.**

Impact printers include *dot-matrix printers* and *daisy-wheel printers.* Dot-matrix printers use tiny pins to strike an inked ribbon, thus transferring ink to paper. Computer software controls the sequence in which the pins strike the ribbon to form letters, numbers, and images. Daisy-wheel printers use a wheel with letters and other characters on it. Software directs the wheel to rotate to the correct position. A hammer hits the positioned character's "spoke," which in turn strikes a ribbon, transferring ink to the paper.

Impact printers are among the earliest types of printers, and they are rarely used today. They are still employed, however, in situations that require impact, such as printing on multiple-sheet forms. Keith Ferrell

A wide variety of printed items—from books, maps, and newspapers to bottles, cans, and articles of clothing—rolls off the presses each day in nearly every part of the world.

Printing

Printing is one of our most important means of mass communication. It is the process by which words and images are reproduced on paper and on such other materials as metal, glass, and fabrics. Printing provides books, tests, and many other study materials for our educational system. Business depends on printing for a wide variety of items, including stationery, order forms, and shipping labels. Printed advertising, from magazine and newspaper advertisements to coupons and billboards, is a popular way to sell goods and services.

Printing is a major industry in many countries. In addition to books, newspapers, magazines, and catalogs, thousands of other items are printed every day. These items include candy bar wrappers, calendars, ruled writing tablets, T-shirts, post cards, playing cards, and reproductions of works of art. Special machines can even print directly on cans or on glass or plastic bottles.

Many people confuse the printing industry with the publishing industry. Publishing is the process of assembling written information and *graphics* (illustrations), and coordinating the production, distribution, and sale of the resulting product. Some publishers own their own printing equipment and do the actual printing of their products, as most daily newspapers do. Most publishers, however, do not own printing equipment. Instead, they contract with a commercial printer to have their books, magazines, or papers printed.

Printing as we know it began in Europe less than 600 years ago. Printing with movable type had existed in East Asia since at least the 700's, but the invention had not spread to Europe. Everything people read had to be copied by hand or printed from wood blocks carved by hand. Then about 1440, the German goldsmith Johannes Gutenberg and his associates developed movable type. Gutenberg made separate pieces of metal type for each character to be printed. With movable type, a printer could quickly make many copies of a book. The same pieces of type could be used again and again, to print many different books.

Printing soon became the first means of mass communication. It put more knowledge in the hands of more people faster and more affordably than ever before. As a result, reading and writing spread widely and rapidly.

This article discusses the preparation of type and illustrations for printing and describes the major commercial printing processes. It also discusses several other printing processes and traces the history of printing. Separate *World Book* articles, such as **Bookbinding** and **Photocomposition**, provide details on various steps in the printing process. Other articles, including **Engrav-**

ing, Etching, Intaglio, and Screen printing, give information on printmaking in the fine arts.

Preparing material for printing

All printing processes follow certain basic steps in preparing text and illustrations for printing. These steps include (1) typesetting, (2) preparing illustrations for reproduction, and (3) page makeup.

Typesetting is the assembly of individual letters and numbers to create the text portion of the printed piece. In the past, skilled workers called *compositors* took individual pieces of carved and cast metal type and manually arranged them, letter by letter, to form lines and pages of text. Mistakes were common, and a sample copy of a complete page, called a *proof,* was checked for errors before proceeding with other steps in the printing process. This checking of sample pages became known as *proofing* or *proofreading,* and it is still a major part of the printing process. See Proofreading.

Three important typesetting processes are (1) electronic imagesetting, (2) hot-metal typesetting, and (3) phototypesetting. Electronic imagesetting is the main typesetting process used today. It can produce both text and graphics. Hot-metal typesetting and phototypesetting produce text only.

Electronic imagesetting uses computers and computer printers to produce many kinds of printed materials, including catalogs, advertisements, and legal documents. Programs for these computers enable users to perform such tasks as word processing, type selection, reproduction of graphics, and *page makeup,* which involves the positioning of both text and graphics on a page. Some programs enable users to stretch letters, condense them, and change them in a number of other ways. A type face, also called a *font,* can be viewed on the computer screen and changed with the push of a key or the click of a button. The computer can also *justify* the text—that is, it can adjust the spacing between words so that all full lines are the same length.

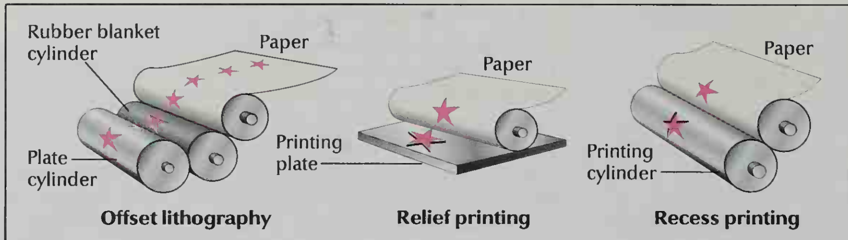
After a page has been designed and the text typed in, the information is converted to a *digital* (numeric) file. A digital file can be used in several ways. It can be transmitted to a desktop printer to produce a proof. The use of desktop machines to typeset and print newsletters, books, newspapers, and magazines is often called *desktop publishing.* A digital file can also be stored on a computer disk for later use. Or it can be sent through a computer network via a device called a *modem.* In a process called *photocomposition,* digital files may be output directly to *laser platesetters.* These machines produce printing *plates,* flat pieces of metal or plastic bearing an image of the material to be printed. Or the digital file can be sent to a *photoimagesetter,* a machine that creates light-sensitive paper or film of complete pages of text and graphics. The paper or film is then used to produce printing plates. See Photocomposition.

Hot-metal typesetting was the dominant form of typesetting from the late 1800's until the mid-1900's. It is still used today for limited printing of greeting cards, diplomas, and specialty items. The process uses molten metal and molds of letters, numbers, and other characters to produce type. A worker sits at a keyboard on a typesetting machine and enters the text to be typeset. The machine retrieves the necessary molds and spaces and arranges them according to the commands.

There are two kinds of hot-metal typesetting machines, the *Monotype* and the *linecaster.* The Monotype molds type character by character. When the typesetter strikes keys on the keyboard, a series of holes are punched into a paper tape. The holes form a code that tells the machine which characters of type are required. A linecaster places a character mold in position for each key struck. When a line is completed, the machine uses hot metal to cast the entire line at once. The most popular type of linecaster is the Linotype.

Phototypesetting produces images of letters and other characters on light-sensitive film or paper. It is also called *cold-type composition.* Phototypesetting was the dominant typesetting process from the 1950's to the 1980's, but it is rarely used today.

Preparing illustrations for reproduction. Printers deal with two main types of graphics, *line reproductions* and *halftone reproductions.* Most printing operations use electronic *scanners,* which record an image with light sensors, or digital cameras to produce digital files of both kinds of graphics. But photographic techniques can also be used to generate either type of image.



Line reproductions are used for *line art*—illustrations that consist of solid areas or solid lines. Such graphics include pen-and-ink drawings, maps, diagrams, and other illustrations without color or shading.

Halftone reproductions are required when the illustrations have a range of tones or shades from dark to light. Such material, called *continuous-tone copy,* includes paintings and photographs. A printing press can print only solid colors, not continuous tones. The illusion of shading, however, can be created by printing a pattern of tiny dots. To the viewer's eye, the dots blend and seem to duplicate the shading of the original art.

Most halftones are produced electronically. First, illustrations are converted to digital code. This may be done by photographing subjects with a digital camera, or by converting prints or slides to digital images using a scanner. A computer is used to determine the organization of the dots for the halftones. In a technique called *AM screening,* the centers of the dots are equally spaced, but the dots vary in size. In *FM screening,* the dots are all the same size, but the spacing between them varies. To learn how color illustrations are printed, see the *Printing in color* section of this article.

Some reproductions are created photographically. Special cameras expose high-contrast film, producing images of the exact size needed for the printed reproduction. For line copy, a simple negative is made. Halftone images can be produced photographically by shooting an illustration through a piece of film called a *halftone screen.* This screen is mounted between the camera lens and the photographic film. It carries a pattern of transparent squares on a black background. As in AM screening, the squares are equally spaced but vary in size. Light reflected from the copy passes through the squares and forms an image on the negative.

Page makeup, also called *image assembly,* involves arranging type and illustrations to form pages. Pages can be assembled by hand, but most designers use computers. Special computer programs enable designers to integrate digital files of text and graphics to assemble pages. On a computer monitor, a designer can

WORLD BOOK illustrations by Paul Perrault

Common printing methods include offset lithography, relief printing, and recess printing. Offset lithography is done from an even surface; relief printing, from a raised surface; and recess printing, from a sunken surface.

see exactly where the text and graphics—represented by boxes called *windows* or *frames*—will appear on a page. The designer can quickly adjust the positions of the windows. When the page is printed, the text and graphics appear where the designer positioned the windows. The page can be printed using a computer printer. The pages can also be output directly to a printing plate, or the image can be transferred onto light-sensitive paper or film that will then be transferred to a printing plate. For certain applications, the output is produced with the graphics windows taking the place of the illustrations.

Platemaking. Once the individual pages are made up, they are *imposed*—that is, put into position for the printing plate. They can be imposed directly from a computer to a printing plate or to paper or film, or the pages can be positioned by hand.

When laying pages out by hand, a specialist called a *stripper* positions film negatives of pages onto a sheet of plastic or special paper in a process called *stripping*. The stripper places dark boxes or cuts out windows where line and halftone negatives will be inserted. If the pages have been laid out on a computer and transferred onto paper or film, the graphics are usually already in position. When everything is in place, the stripper cuts away the paper or plastic from the image areas, allowing the image to transfer onto a light-sensitive printing plate. The plate picks up these images for reproduction on the printing press.

Methods of printing

Most commercial printing today is done by one of four processes: (1) offset lithography, a type of planographic printing; (2) relief printing; (3) recess printing, also called gravure printing; (4) and digital printing. Each of these processes uses a different kind of printing surface to carry the images to be printed. In offset lithography, the most widely used process, the printing surface and the nonprinting surface are on the same level. In relief printing, which includes *letterpress* and *flexographic* processes, the printing surface is raised. In recess printing, which includes engraved printing, the printing surface is below the nonprinting surface. Digital printing uses an electrically charged drum and a dry or liquid ink called *toner,* or *inkjets* that drop or spray ink on the printing surface without even touching it.

Printing presses print on sheets or rolls of material called a *substrate*. Usually the substrate is paper, but other common substrates include plastics, foils, and cardboard for packaging. Presses that print on sheets are called *sheet-fed presses*. Those that print on rolls are called *web-fed presses* or *web presses*. A roll of substrate is called a *web*.

Offset lithography is based on the fact that grease and water do not mix. The process is also more simply called *offset* or *lithography*. Alois Senefelder, a German printer, discovered the principle of lithography in 1798. He drew a design on a smooth, flat stone with greasy crayon. Then he dampened the stone, and the water stuck only to the parts not covered by the design. Next, he inked the stone, and the ink stuck only to the design. He then pressed paper against the stone and transferred the image to the paper.

In offset lithography, thin metal plates have replaced Senefelder's stone, and the images are put on the plates photographically, or electronically using a laser. The inked images do not print directly on the paper that is fed through the press. Instead, the images are *offset* (transferred) to a rubber-covered cylinder, called a *blanket cylinder,* which in turn offsets them to the paper or other substrate.

Almost anything can be printed by offset lithography. The process is used for such items as books, cards, magazines, stationery, cans, cartons, business forms, labels, and newspapers. Nearly half of all printing today is done by offset lithography.

Offset printing plates may be either *negative-working* or *positive-working*. Negative-working plates are made photographically from negatives assembled during page makeup. The negatives are held by vacuum pressure against a metal plate with a coating that hardens when exposed to light. Powerful lamps shine light through the transparent parts of the negatives, hardening the image areas on the plate. The plate is treated with a solution of developer and lacquer. The lacquer adheres only to the image areas. The plate is washed, and a gum is applied to thoroughly cleanse the nonimage areas so they will reject any ink. During printing, only the lacquered areas accept ink. Positive-working plates require film positives or specially treated paper. They are made by photographing negatives or by printing the negatives on film or paper.

Some offset plates can receive images directly in an imagesetting or platesetting device, eliminating the use of paper or film. This process is referred to as *computer-to-plate* or *direct-to-plate*. Images are transferred as a digital code. This code is then read by a laser platesetter, which then produces the printing plates.

Offset presses are *rotary* presses—that is, they use revolving cylinders to hold both the printing plate and the substrate. An offset press prints from a curved printing plate clamped to a rotating *plate cylinder*. As the cylinder rotates, it presses against dampening rollers, which wet the plate so the nonprinting areas will repel ink. The cylinder next passes against inking rollers, and ink sticks

only to the image areas. The turning plate cylinder then offsets the inked images onto a rotating *blanket cylinder,* a cylinder covered with a rubber blanket. The blanket cylinder offsets the images onto the paper or other substrate carried by an *impression cylinder.* This assembly of rollers and cylinders is known as a *printing unit.*

In a sheet-fed offset press, sheets of paper pass through the printing unit one at a time. Sheet-fed presses have one, two, four, or more units. In presses with multiple printing units, each unit prints a different color. Some sheet-fed presses are *perfecting presses*—that is, they print both sides of the paper in a single pass.

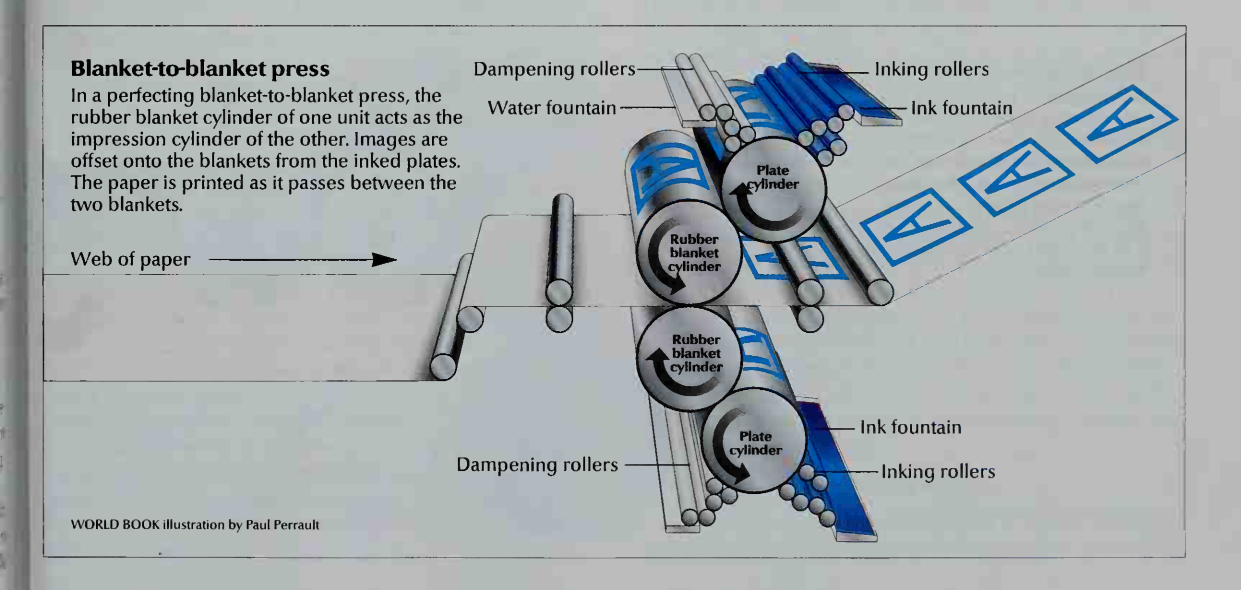
After a worker sets up the press, sample copies are printed. Then, in a process called *makeready,* the printer makes adjustments to get the best impression. If more than one color is being printed, the *register* (alignment) of the colors is adjusted during makeready.

Most web-fed offset presses are multicolor perfecting, blanket-to-blanket presses. These presses do not use impression cylinders. The web of paper passes between the blanket cylinders of two units. The blanket cylinder of each unit serves as the impression cylinder for the other. The paper is printed on both sides as it passes between the blankets.

Next, the paper is gathered onto another roll, or it is cut and folded into groups of pages called *signatures.* Some presses are fitted with high-speed staplers, called *stitchers,* that produce finished, stapled magazines. Other presses have gluers and cutters that create envelopes or three-dimensional printed pieces, such as stand-up displays or pop-up greeting cards.

Offset presses are fast. Sheet-fed presses can print up to 250 sheets per minute. Some web presses can run at speeds of 3,000 feet (900 meters) per minute.

Relief printing is the oldest printing method. More than 1,300 years ago, people in East Asia printed from wood blocks. They carved the nonprinting areas from the surface of a piece of wood, leaving characters and designs *in relief* (raised). They inked the raised surface, placed a sheet of paper on the block, and transferred the ink to the paper by rubbing the back of the sheet.



There are two common forms of relief printing used today, flexographic printing and letterpress printing.

Flexographic printing. Flexographic plates are made of rubber or soft plastic. Their softness makes them especially useful for printing on materials that should not be squeezed too hard, such as corrugated paper, foils, and plastics. Almost anything that can go through a web press can be printed flexographically. Such items include newspapers, cardboard cartons, and gift wrap.

Flexographic plates can be made photographically or by laser. In the photographic method, a metal or plastic sheet is exposed to ultraviolet or other special light through a negative. The sheet is chemically treated so that the part exposed to light hardens. The nonimage areas remain soft and can be washed away, thereby creating a plate with raised image areas. This plate is pressed into cardboard or soft plastic, leaving a negative relief of the image. The negative relief is then used as a mold or *mat.* A sheet of rubber or plastic is pressed into the mold under heat and pressure, forming a positive relief plate. The other method for making flexographic plates uses a laser to cut an image from a specially treated rubber plate or cylinder.

Flexographic presses use a single roller to apply ink to the printing plate. A *doctor blade* scrapes excess ink from the roller, which rotates inside an ink fountain. Flexographic presses squeeze the paper or other substrate between an impression cylinder and a plate cylinder. The impression pressure is adjusted to the minimum needed to get a clear reproduction. This light impression is called a *kiss impression.*

Letterpress printing. A letterpress printing press uses plastic or metal relief printing plates or *type forms.* A type form consists of type and other material locked in a metal frame for printing. Letterpress dominated printing from its invention in the mid-1400's until the mid-1900's. Letterpress declined in popularity largely because its text and halftone image quality is not as good as that produced by offset. In addition, letterpress makeready tends to take a long time and waste much paper. Today, the letterpress process is used only by specialty print-

Blanket-to-blanket press

In a perfecting blanket-to-blanket press, the rubber blanket cylinder of one unit acts as the impression cylinder of the other. Images are offset onto the blankets from the inked plates. The paper is printed as it passes between the two blankets.

ers. Most items that were once printed by letterpress are printed by offset today. Others, including some newspapers, are produced by flexography.

Letterpress printing plates are made photographically, in a process similar to that used for flexographic plates. The plastic or metal plates are chemically treated so that the surface hardens in image areas that are exposed to light. The nonimage areas remain soft and can be removed with water, a chemical solution, or a blast of air. Removing these areas leaves the image in relief. The plate is then hardened further before printing.

Letterpress printing presses include *platen, flat-bed,* and rotary presses. Platen presses have two main parts. A *bed* holds the type form or printing plate, and a metal plate called a *platen* holds the paper to be printed. The two parts are both flat, and they are joined together like a clamshell. Rollers ink the form or plate as a sheet of paper is fed to the platen. The platen then swings against the printing surface and prints the sheet as the rollers roll back to get more ink from an inking plate. As the platen swings back, the printed sheet is released.

Flat-bed presses move the type form, which rests on the flat bed of the press, against a rotating impression cylinder. The paper, which is attached to the cylinder, is printed as it rolls over the form.

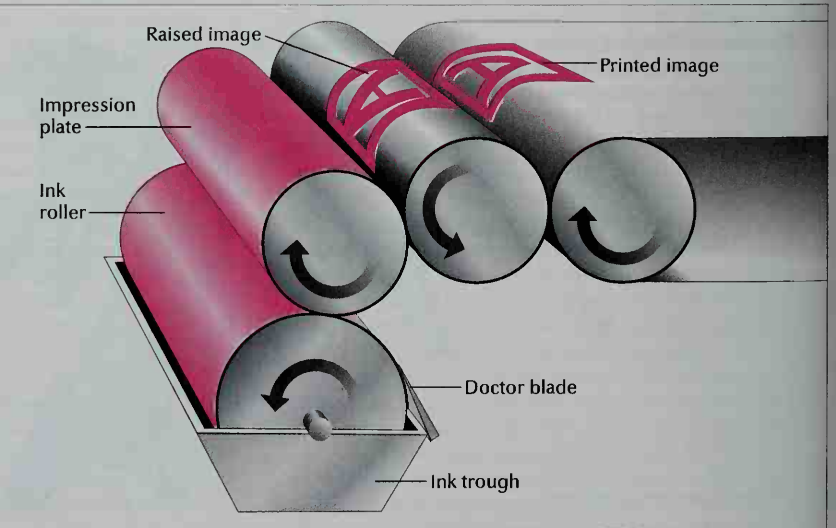
Rotary presses for letterpress printing are similar to those used in flexographic printing. Rotary presses are used today for specialty letterpress printing.

Recess printing, also called *gravure printing,* is an *intaglio* (pronounced *ihn TAL yoh)* method of printing. The words, pictures, or designs to be printed are sunk into a printing cylinder or plate. Gravure is used to print a wide variety of items. They include the magazine sections of newspapers, catalogs, postage stamps, stock certificates, floor tiles, wallpaper, boxes, and gift wrap.

Gravure cylinders. Most commercial recess printing processes use printing cylinders rather than plates. This process is also called *rotogravure.* Most gravure cylinders are made by *electromechanical engraving.* In this process, an electronic scanner scans the original copy or offset film. The scanner sends signals to a computer, which directs a machine equipped with diamond-pointed cutting tools called *styluses.* The styluses cut thousands of little pits called *cells* into the copper covering of the cylinder. The cells vary in area and depth. On the printing press, the deepest cells hold the most ink and print the darkest tones. The shallowest cells hold the least ink and print the lightest tones.

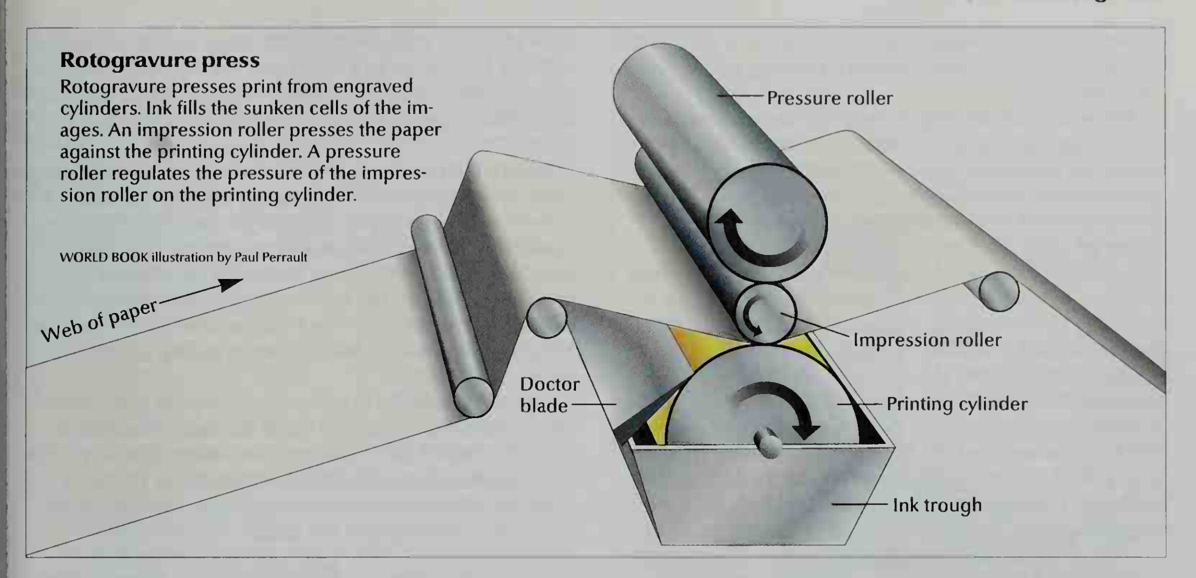
Another method of gravure involves putting images on the printing cylinder photographically. The copy to be printed is photographed and made into film positives. The halftone method is not used. The positives are then assembled as they are to appear in print. Next, the images on the positives are transferred to the printing surface through the use of *carbon tissue,* a sheet of paper covered with light-sensitive gelatin. The carbon tissue is first exposed under bright light to a screen called a *gravure screen* to create a grid of light-hardened lines and softer squares on the tissue. Then the carbon tissue is exposed to the film positives. The gelatin hardens further according to how much light passes through the positives. The gelatin becomes hardest and thickest where the most light passes through.

The exposed tissue is placed gelatin side down on a heavy copper-plated cylinder. The tissue is developed in water, and the paper backing is stripped off. A layer of gelatin made up of tiny squares of varying thickness is left standing on the copper. The cylinder is then bathed in a corrosive solution. The solution eats through the gelatin squares and bites small cells into the copper. It quickly penetrates the thin squares and bites deepest into the cylinder in these areas, which thus print darkest. This process is known as *etching.*



The *direct transfer* method of gravure does not use carbon tissue. Instead, a light-sensitive coating is applied directly to the cylinder and exposed to light through a halftone positive film.

Modern methods use a computer to control a laser that engraves the image directly onto the cylinder. The computer issues its instructions using information from digital files of text and graphics.



Gravure presses are usually web-fed rotary presses.

Flexographic press

A flexographic press uses a flexible printing plate wrapped around a cylinder. Ink is transferred from an ink roller to an impression cylinder. The raised image on the plate picks up ink from this cylinder and transfers it to the paper or other surface being printed.

WORLD BOOK illustration by Paul Perrault

Rotogravure press

Rotogravure presses print from engraved cylinders. Ink fills the sunken cells of the images. An impression roller presses the paper against the printing cylinder. A pressure roller regulates the pressure of the impression roller on the printing cylinder.

WORLD BOOK illustration by Paul Perrault

Rotogravure presses can run at speeds of more than 3,000 feet (900 meters) per minute. In most gravure presses, the printing cylinder rotates with its bottom edge in a trough of ink. As the cylinder turns, the cells fill with ink. A doctor blade wipes the surface clean so that the ink remains only in the cells. An impression roller presses paper against the printing cylinder and into the cells. The pressure transfers the ink in each cell to the paper. This transfer is assisted by the addition of an electrical device that creates a negative electric charge in the gravure cylinder and a positive charge on the impression cylinder. Opposite charges attract, and those on a gravure press make the ink inside the cells jump to the paper as it passes by.

Digital printing, also called *electronic printing,* is done with desktop printers or copying machines. A desktop printer requires a stream of digital data, and a copier requires an original document.

A *laser printer* is used with a computer and digital files of text and graphics. It uses a laser to give a negative electric charge to a cylinder in a pattern that corresponds to the text and graphics to be printed. Positively charged toner is attracted to the negatively charged areas. A piece of paper is pressed onto the cylinder, where it receives the toner. The paper is then passed through heated *fuser rollers,* which cause the toner particles to adhere to the paper.

Copying machines are used to duplicate printed documents. In most copiers, the original copy is scanned and converted to a pattern of dots. A laser transfers this pattern to a drum as electric charges. The copier then uses toner, paper, and fuser rollers just as a laser printer does. Some older copiers use reflected light from a special bulb to focus the copy through a lens onto a negatively charged drum. The image forms on the drum as a pattern of positively charged particles.

Some printers and copiers use inkjet technology. An inkjet squeezes small drops of ink onto a slowly moving sheet of paper to produce an image. Or it uses an array of nozzles to eject the ink continuously on a fast-moving web of paper.

Digital printing requires a new image to be created on the drum for each copy. Thus the process is capable of producing personalized direct mail, *on-demand* (one at a time) publications, and other customized printed products. All other printing methods are better suited for print runs of over 500 copies.

Other printing processes include screen printing and collotype printing.

Screen printing requires a stencil and a fine cloth or screen. The stencil carries the design to be printed. Ink is squeezed onto the printing surface through the areas of the screen not covered by the stencil. The stencil can be cut from paper. Or it can be made by tracing a design directly on the screen and blocking out the nonprinting areas with glue or lacquer. A stencil can also be made by giving the screen a light-sensitive coating and putting the design on it photographically or by laser.

The screen printing process can be used to print on paper, glass, cloth, wood, or almost any other material. It can print on objects of various sizes and shapes, including draperies, bottles, toys, and furniture. Screen printing can be done using automatic or hand-operated presses. Screen printing is also called *silk-screen printing* or *serigraphy.*

Collotype printing is similar to lithography. A metal or glass plate is coated with a light-sensitive gelatin. The gelatin is exposed to light under an unscreened negative that carries the image to be printed, and the gelatin hardens to varying degrees. The plate is then soaked in a solution of water and glycerin. The hardest parts of the gelatin absorb the least solution, and the softest parts absorb the most. On the printing press, the hardest, driest parts accept the most ink and print the darkest tones. The softest, wettest parts accept the least ink and print the lightest tones. Collotype is sometimes used to print post cards, greeting cards, posters, and high-quality reproductions of paintings.

Printing in color

Lithography, relief printing, recess printing, and digital printing can reproduce anything in color—from com-

ic strips to masterworks of art. There are two chief kinds of color printing: (1) process color printing and (2) flat color printing.

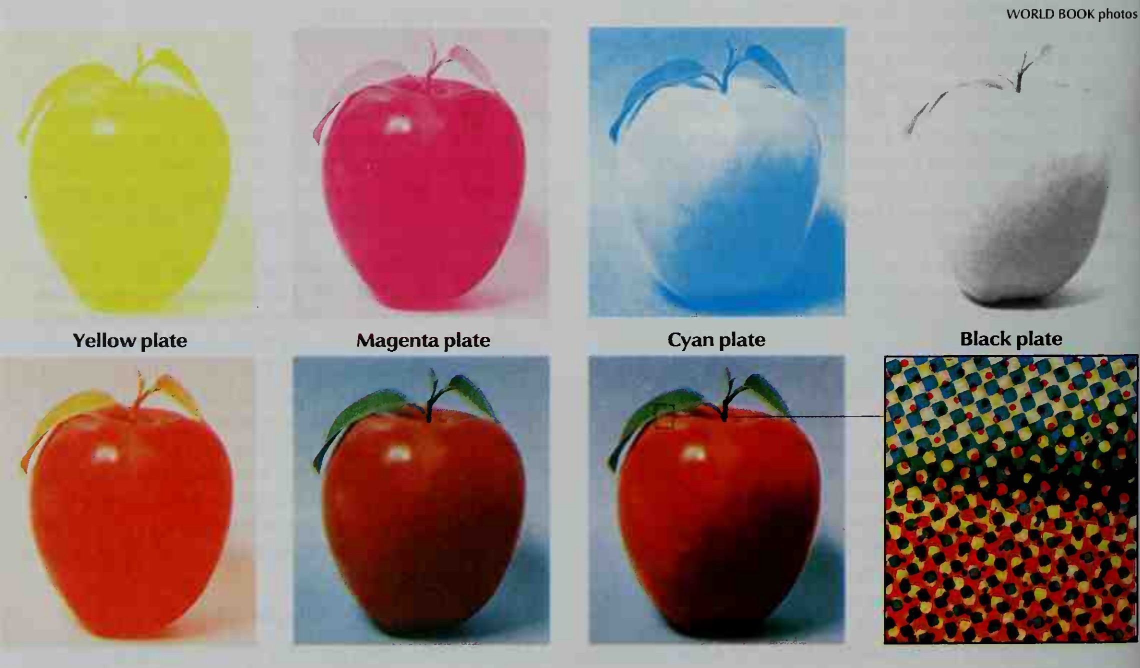
Process color printing is used mainly to reproduce color copy that contains shades or tones. Such copy includes oil paintings, water-color paintings, and color photographs. Process color printing uses tiny dots of transparent ink in the colors yellow; *magenta* (pronounced *muh JEHN tuh),* a purplish-red; *cyan* (pronounced *SY an),* a blue; and black. With only these four colors of ink, process color printing can reproduce almost any color and tone. Sometimes, colors other than these are used to achieve special effects.

Most printing operations use an electronic scanner to separate the colors in the copy. A scanner produces digital files that represent the yellow, magenta, cyan, and black components of the copy. If a halftone dot pattern is required, a scanner can generate such a pattern for each color. In printing, some of the tiny dots fall close together, some overlap, and some fall on top of others. To the viewer's eye, the colors of the dots appear to be all the colors and shades of the original copy. For example, what the eye sees as green is an area of tiny cyan and yellow dots. The digital files produced by the scanner can be stored, and they can later be output to digital printers, imagesetters, or platesetters.

In color lithography, relief printing, and recess printing, after the separations have been made, the steps follow the standard procedures for making printing plates or cylinders. On a four-color press, there are four plates. Each plate has its own supply of either yellow, magenta, cyan, or black ink. On a four-color rotary press, paper passes from one set of cylinders to the next, picking up the different colors and emerging from the press fully printed.

Before the development of scanning technology, the color components were separated photographically. A camera was used to photograph the copy four times to create a *separation negative* of the yellow, magenta, cyan, and black in the copy. Each time, a different colored filter was used to block out all colors from a negative except the desired one. Printers used the separation negatives to produce relief or offset plates, or gravure plates or cylinders.

Flat color printing is used chiefly to print *line copy* in solid colors. Such copy includes diagrams, headlines and other type matter, and trademarks on stationery. Flat color printing is simpler than process color printing. Separate plates are made for each color of opaque ink. Halftone screenings are not used.



History

The history of printing can be traced back thousands of years, to when people in the Middle East learned to press carved designs into wet clay. More than 2,000 years ago, the Chinese invented paper. By the 700's, the Chinese, Japanese, and Koreans were using block printing. They carved symbols and pictures on wood blocks, inked the raised images, and transferred the ink to paper.

Printing with process colors

To reproduce a color picture, printers usually make four printing plates—one each to print yellow, magenta, cyan, and black ink. In reproducing the picture of the apple, printers first printed the yellow plate. Then they printed the magenta plate, producing a picture made up only of yellow and magenta tones. Printing the cyan plate next made a picture of yellow, magenta, and cyan tones. The black plate was then printed to add sharpness to the picture. The magnified area shows how the colors of all the plates combine to form the tones of the picture.

The invention of movable type. About 1045, a Chinese printer named Bi Sheng (Pi Sheng) made the first movable type. He made a separate piece of clay type for each Chinese symbol or character. But the Chinese language required so many different characters for printing that the method was difficult and fell into disuse. Printers found it easier to print from wood blocks.

While the people of East Asia were printing from wood blocks, the people of Europe still copied books by hand. Many monks spent their lives copying books with quills and reeds. In the late 1300's, Europeans discovered wood-block printing. The earliest dated European wood-block print is a picture of Saint Christopher, printed in 1423. About this time, Europeans began to produce *block books* by binding prints together.

Meanwhile, a major revival of art and learning called the Renaissance was sweeping through Europe. The great desire for learning created a huge demand for books that hand copying and block printing could not satisfy. Movable type solved the problem.

Printing as we know it today began about 1440 with the first use of movable type in Europe by Johannes Gutenberg and his associates in Germany. Gutenberg brought together several inventions to create a whole new system of printing. He made separate pieces of metal type, both capitals and small letters, for each letter of the alphabet. He assembled the pieces of type in a frame to form pages. Finally, his press, based on the idea of a wine press, became the first printing press in Europe. Gutenberg had found it hard to produce evenly printed copies by pressing the paper against the type by hand. By turning a huge screw on the press, he could put uniform pressure on the paper. The Gutenberg press could print about 300 copies a day. By 1456, the famous Gutenberg Bible was completed.

Many people feared that the new art of printing was a "black" art that came from Satan. They could not understand how books could be produced so quickly, or how all copies could look exactly alike. In spite of people's fears, printing spread rapidly. By 1500, there were more than 1,000 print shops in Europe, and several million books had been produced.

WORLD BOOK illustration by Tom Dunnington

Gutenberg's press probably looked like this drawing. It was based on the idea of a wine press and could print about 300 sheets a day. It produced the magnificent Gutenberg Bible.

Early printing in North America. In 1539, an Italian printer, Juan Pablos (Giovanni Paoli), set up a print shop in Mexico City. This was the first print shop in North America. In 1639, Stephen Daye and his son Matthew set up the first press in the American Colonies, in Cambridge, Massachusetts.

Printing spread quickly through the colonies, though the colonial authorities often placed strict controls on printers. The early printers were America's first publishers of newspapers, books, and magazines. In 1704, John Campbell established *The Boston News-Letter,* the first regularly published paper in the colonies. In 1751, Bartholomew Green of Boston set up Canada's first print shop in Halifax, Nova Scotia. Green died that same year, and his former assistant, John Bushell, took over the shop. In 1752, Bushell began publishing the *Halifax Gazette,* Canada's first newspaper.

New presses and typecasting machines. There were few changes in the printing press from Gutenberg's time until the 1800's. An English nobleman, the Earl of Stanhope, built the first all-iron press about 1800. In 1811, the German printer Friedrich König invented a steam-powered cylinder press. This press used a revolving cylinder that pressed the paper against a flat bed of type. *The Times* of London used the press for the first time in 1814. It could print 1,100 sheets per hour.

In 1846, Richard M. Hoe of the United States, a manufacturer of printing presses, invented the rotary press. He attached type to a revolving cylinder and used another cylinder to make the impression. The first Hoe presses printed 8,000 sheets per hour. Later models turned out 20,000 sheets per hour. In 1865, William A. Bullock, an American inventor and machinist, found a way to print from a continuous roll of paper and invented a high-speed web-fed rotary press.

Until the 1880's, printers set all type by hand, just as Gutenberg had done over 400 years before. In 1884, Ottmar Mergenthaler, a German instrument maker living in the United States, patented the Linotype. This machine uses a keyboard to cast a full line of type in one piece of metal, thus eliminating the need for hand-setting. In 1887, Tolbert Lanston, an American inventor, developed the Monotype, which casts and sets separate pieces of type.

Developments in platemaking. In 1826, Joseph Nicéphore Niépce, a French physicist, produced the world's first photograph. This achievement, and further

developments in photography, made possible photoengraving, the halftone process, and photolithography and modern offset printing.

In 1852, William H. Fox Talbot, an English photographer, patented photoengraving. Two American photoengravers, Max and Louis Levy, perfected the halftone screen in the 1880's. Alphonse Louis Poitevin, a French chemist, engineer, and photographer, invented photolithography in 1855. By the late 1800's, offset presses appeared in Europe. These early presses were used to print tin sheets for making cans and boxes.

About 1905, Ira Rubel, a U.S. papermaker and printer, accidentally discovered the offset method for printing on paper. While running his press, Rubel unintentionally transferred the inked images onto the rubber-covered impression cylinder, instead of onto paper. Then, when he ran paper through the press, the impression cylinder offset the images onto the paper. Rubel noticed that the offset images were unusually sharp. Improvements in the offset press followed, and offset printing quickly came into general use.

The electronic age. Since the 1930's, more advances have been made in printing than in all the years since Gutenberg. By the mid-1940's, advances in photolithography and offset printing made it possible to print with better quality, consistency, and cost-efficiency than the relief process could offer. The combination of photographic processes and offset printing brought more complex illustrations and photographs to printed pieces, as well as more brilliant and lifelike colors. By the 1960's, photoengraving and offset printing had become so simplified that certain kinds of printing could be done in minutes, giving rise to a new kind of commercial printing called *quick printing.*

Desktop publishing began in the mid-1980's. New computers, computer printers, and software enabled people to design, edit, and print material that traditionally would have been produced on printing presses. In the late 1900's, inventors developed processes for putting images onto paper and other materials directly from computer files, without an intermediate step.

Prion, *PREE ahn,* is a microscopic particle that causes a group of fatal brain disorders called *prion diseases.* Brain tissue damaged by prions looks spongelike under a microscope. Prion diseases include Creutzfeldt-Jakob disease in people, mad cow disease in cattle, and scrapie in sheep and goats. Scientists have not fully determined the structure of prions. But the particles consist largely—and possibly entirely—of a protein called *prion protein.* Most proteins are large molecules with complex three-dimensional shapes. Disease-causing prions contain abnormally shaped forms of prion protein.

Prion protein in its normal shape occurs naturally in the brains of all mammals and birds. The leading explanation for prion diseases is that once the misshapen protein enters the brain, it transforms the normal protein to an abnormal shape. Newly deformed prion protein then transforms more normal protein until brain function is destroyed. Disease-causing prion protein can enter the brain as an infectious agent from outside the body. Abnormal forms can also arise within the brain. The transformation may begin spontaneously or occur due to an error in a *gene* (a unit of heredity that determines the structure of proteins). Infectious prions are unique because they have no genes of their own. All other known infectious agents contain genetic material.

Prism is a solid that has two parallel bases joined by three or more *lateral surfaces* (sides). The bases are

Arnold Ryan

A prism splits a beam of white light, *lower right,* into a band of colors called a *spectrum, upper left.* The light ray at the lower left is a reflection of the original beam.

polygons that have the same size and shape. The lateral surfaces are parallelograms.

There are many types of prisms. The simplest has triangular bases. In a *right prism,* the lateral surfaces are perpendicular to the bases. Prisms that do not have this property are called *oblique prisms.*

Prisms form an important class of optical elements. Prisms made of glass or quartz are used in a variety of instruments to change the direction of a beam of light. For example, periscopes contain right prisms that reflect light at a right angle to its original direction. In binoculars, the direction of the light is reversed after the light is reflected off two sides of the prism.

Prisms also can change the direction of a beam of light by means of *refraction*—that is, they can bend the light as it passes through them. The angle at which light is refracted depends on its wavelength. Different colors of light have different wavelengths. If a beam of white light, which contains all the wavelengths of visible light, passes through a prism, it is split up to form a band of colors called a *spectrum.* For this reason, prisms are part of spectrometers and other instruments that measure the spectral composition of light. Brian J. Thompson

Prison is an institution for confining and punishing people who have been convicted of crimes. Prisons punish criminals by severely restricting their freedom. For example, prisons limit where *inmates* (prisoners) may go, what they may do, and with whom they may associate. Inmates serve sentences ranging from a year to the rest of their lives. Prisons are important because they help protect society from dangerous criminals.

Prisons throughout the world hold more than 8 million people. Russia and the United States have the highest percentages of prisoners in their populations. Denmark, France, Germany, Italy, Japan, the Netherlands, and Sweden have relatively low prison populations.

In some countries, such as Israel and the Philippines, the federal government operates the prisons. The major political divisions of the United Kingdom each have their own prison agency, called the Prison Service in England and Wales, the Scottish Prison Service, and the Northern Ireland Prison Service. In Australia and India, the states have responsibility for running the prisons. In Canada and the United States, both the federal government and the state or provincial governments maintain prison systems. The Federal Bureau of Prisons oversees federal prisons in the United States, and the Correctional Service of Canada operates those in Canada.

Types of correctional institutions

There are various names for institutions that confine convicted lawbreakers or people awaiting trial. The most common terms include *penitentiaries, correctional centers, correctional facilities,* and *reformatories.* Many people consider prisons to be only those institutions that confine adults convicted of major crimes. Institutions for youthful offenders include *training schools* and *juvenile detention centers.* In addition, such facilities as *city and county jails, federal detention centers,* and *metropolitan correctional centers* hold people who are awaiting trial or serving sentences for minor offenses. Most prisons house only male or only female inmates.

Experts classify prisons by the degree of security or control they provide. The main types are (1) maximum security prisons, (2) medium security prisons, and (3) minimum security prisons.

Maximum security prisons generally hold prisoners serving long sentences. These prisoners have committed murder, robbery, kidnapping, treason, or other *felonies* (serious crimes).

High stone walls or strong chain fences surround most maximum security prisons. Many of these barriers have electronic detection devices and powerful spotlights. Prisoners live in cells with steel bars or heavy gratings on one side. Many cells do not have windows. Inmates eat in their cells or in a dining hall. Prison officials limit the length and number of visits by family and friends. During such visits, thick glass or wire screens separate some prisoners and visitors to prevent the exchange of such items as drugs and weapons. Other prisoners and visitors are allowed to be together. Some prisons use X-ray devices to check visitors for weapons.

Since the mid-1980's, a number of prison systems have developed *supermaximum security prisons,* often called *supermax prisons.* These prisons hold prisoners who cannot be controlled by other means. Common features of supermax prisons include total separation, restricted movement, and limited access to staff members and other inmates.

Medium security prisons hold inmates who have committed either felonies or *misdemeanors* (crimes less serious than felonies). Common misdemeanors include assaults and small thefts. The inmates in medium security prisons are generally less dangerous than inmates of maximum security prisons. Some medium security prisons resemble campuses, though they may be surrounded by fences with guard towers. Inmates may live in dormitories or in private rooms. Many of these prisons have educational and athletic facilities.

Minimum security prisons are the most open and least restrictive prisons. Inmates of minimum security prisons are not considered dangerous and are unlikely

B. Charlon, Gamma/Liaison

A maximum security prison holds prisoners convicted of the most serious crimes. Such prisoners may leave their cells only to eat, work, or participate in educational programs.

to flee prison. Many of these inmates were convicted of such nonviolent crimes as forgery, cheating on taxes, business theft, perjury, and obstruction of justice. They live in comfortable rooms and usually may move about within the prison as they please. Minimum security prisons range from large institutions to small farm or forestry camps. Some of these prisons have tennis courts, swimming pools, and golf courses.

Juvenile correctional institutions generally hold offenders under the age of 18. The institutions keep young prisoners from the bad influence of dangerous adult criminals. Juvenile detention centers, called *remand centres* in the United Kingdom, hold young people who have been accused of committing crimes and are awaiting trial. Training schools are institutions where convicted youths serve their sentences. Most of these sentences last about a year. Training schools offer counseling, education, job training, and recreation. The inmates live and eat together in cottages or dormitories that hold fewer than 20 prisoners.

Jails, also spelled *gaols,* hold people awaiting trial. They also house people convicted of the least serious crimes. Jail inmates include people accused of serious crimes as well as such offenders as disorderly and intoxicated persons. Prisoners may stay in jail for only a few hours or for more than a year.

Conditions in most jails are worse than those in other correctional institutions. Jails often are overcrowded, and the same facility may hold both men and women, and adults as well as juveniles. Some prisoners are kept in small cells, and others are crowded together in large cells. Many jails do not meet minimum health and safety standards, and some cells lack a sink or a toilet. Most jails have few professionally trained staff members.

How prisons operate

Prisons have four major purposes. These purposes are (1) *retribution,* (2) *incapacitation,* (3) *deterrence,* and (4) *rehabilitation.* Retribution means punishment for crimes against society. Depriving criminals of their freedom is a way of making them pay a debt to society for their crimes. Incapacitation refers to the removal of criminals from society so they can no longer harm innocent people. Deterrence means the prevention of future crime. Supporters of deterrence hope that prisons provide warnings to potential criminals, and that the possibility of going to prison will discourage people from breaking the law. Rehabilitation refers to activities designed to change criminals into law-abiding citizens. Rehabilitation efforts may include providing educational courses, teaching job skills, and offering counseling with a psychologist or social worker.

Through the years, prison systems have stressed the four major purposes differently. As a result, prisons differ in the makeup of their staffs, the design of their buildings, and their operations.

The prison staff is headed by a *warden, superintendent,* or *governor* who directs the operation of the prison. This official is held responsible if there are such problems as riots, escapes, prison mismanagement, and brutality toward prisoners. *Prison guards,* also called *warders,* observe and supervise the inmates. Many prison guards take an examination to qualify for their jobs. Many prison staffs also include teachers, social workers, psychologists, and doctors and nurses.

Prison buildings vary greatly in design. Prisons built in the *radial design* resemble the hub and spokes of a wheel. The cells, dining hall, and other facilities extend from the control center at the hub. Guards at the control center can observe all activity within the building. Most maximum security prisons use the *telephone pole design.* They consist of a long corridor crossed by shorter corridors that hold the cells and other facilities. Prisoners must use the central corridor when they move from place to place. This design allows close supervision by the guards. The *high-rise design* is a vertical version of the telephone pole design. Prisoners move from floor to floor by elevator. The *campus design* resembles a group of small apartment buildings around a town square. It is commonly used for juvenile institutions and may include such facilities as a church, a school, and a library.

Prison cells are generally small and simply furnished. Some may contain only a bed, a sink, and a toilet. Prisoners who are hard to control may be placed for a time in a *segregation cell* (solitary confinement). Most segregation cells have dim lighting, poor ventilation, and inadequate sanitary facilities. Segregation cells may have only a mattress on the floor or a stone slab on which the prisoner sleeps.

Special facilities and services may be provided for inmates, depending on the views of prison officials and the availability of funds. Prisons may have libraries and athletic facilities for inmates. Prisons may offer counseling, medical care, motion pictures, and religious services. Some prisons offer courses for high school or college credit, or provide job training in such fields as automobile repair and carpentry.

Some prisons operate their own farms or factories and use inmates as workers. Some of these prisons pay inmates for their labor. By providing goods for the prisoners' use, prison farms and factories help prisons reduce their operating costs. China, Poland, and the Netherlands, in particular, emphasize reform through prison labor. Some prisons run *work-release programs,* in which trusted inmates may leave prison during the day for an outside job.

A cell in a maximum security prison has steel bars to keep the prisoner inside. Other features of this cell include a bed, a cylindrical seat, and a table, a corner of which can be seen above the seat.

History

Early prisons. Before the 1700's, governments seldom imprisoned criminals for punishment. Instead, they imprisoned people who were awaiting trial or punishment. Common punishments at that time included branding, fines, whipping, and *capital punishment* (execution). The authorities punished most offenders in public to discourage others from breaking the law.

English and French rulers kept their political enemies in such prisons as the Tower of London and the Bastille in Paris. People who owed money went to *debtors' prisons.* In many cases, offenders' families could stay with them and come and go as they pleased. But the debtors had to remain in prison until their debts were settled.

During the 1700's, many people criticized the use of executions and other harsh punishments. These critics included the British judge Sir William Blackstone. As a result, governments turned more and more to imprisonment as a form of punishment.

Early prison reform. Early prisons were dark, dirty, and overcrowded. They locked all types of prisoners together, including men, women, and children, plus dangerous criminals, debtors, and the insane. During the late 1700's, the British reformer John Howard toured Europe to observe prison conditions. His book *The State of the Prisons in England and Wales* (1777) influenced the passage of a law that led to the construction of the first British prisons designed partly for reform. These prisons attempted to make their inmates feel *penitent* (sorry for doing wrong) and became known as *penitentiaries.*

In 1787, a group of influential Philadelphians, mostly Quakers, formed the Philadelphia Society for Alleviating the Miseries of Public Prisons (now the Pennsylvania Prison Society). They believed that some criminals could be reformed through hard work and meditation. The Quakers urged that dangerous criminals be held separately from nonviolent offenders and men and women prisoners be kept apart. These ideas became known as the Pennsylvania System, and were put into practice in 1790 at Philadelphia's Walnut Street Jail. Historians consider this jail the first prison in the United States.

The Pennsylvania System was the first attempt to rehabilitate criminals by classifying and separating them on the basis of their crimes. As a result, the most dangerous inmates spent all their time alone in their cells. In time, the system failed, chiefly because overcrowding made such separation impossible. Some inmates in this system became insane because of long isolation.

During the 1800's, New York prison officials developed two major systems of prison organization—the Auburn System and the Elmira System. The Auburn System, introduced at Auburn (New York) Prison in 1821, became widely adopted. Under this system, prisoners stayed in solitary confinement at night and worked together during the day. The system emphasized silence.

© A. Ramey, Woodfin Camp, Inc.

Guard towers and high fences surround many maximum security prisons. Prisoners dressed in white can be seen inside the fence that surrounds this prison. On the tower, a guard with a rifle watches over the prison yard.

Prisoners could not speak to, or even look at, one another. Prison officials hoped that this silence and isolation would cause inmates to think about their crimes and reform. They believed that the prisoners' spirit must be broken before reform could take place. However, the system failed partly because the rigid rules and isolation drove inmates insane.

In 1876, the Elmira (New York) Reformatory opened as a model prison for offenders between the ages of 16 and 30. The Elmira System made use of *indeterminate* (flexible) sentences and allowed prisoners to earn *parole* (early release) for good behavior. In addition, it offered physical and military training and an educational program. The reformatory's emphasis on rehabilitation through education became its major contribution. However, it did not fully achieve its expectations, largely because it judged inmates on their prison behavior instead of on their actual fitness for release. Studies showed that most inmates committed new crimes after their release.

Reforms in the 1900's led to further improvement of prisons. In the 1930's, for example, prisons began to develop rehabilitation programs based on the background, personality, and physical condition of the individual inmate. This approach made rehabilitation programs more meaningful. But despite such efforts, attempts to rehabilitate offenders had disappointing results. Many failed because of poorly trained staffs, lack of funds, and ill-defined goals.

By the 1960's, many people felt that criminals could be helped better outside prison. As a result, federal and state governments began to set up *community correctional centers* and *halfway houses*. Offenders lived in these facilities just before release and received counseling to help them adjust to life outside prison. The number of prison inmates declined. But community correction programs also failed to meet expectations, and prisons again became the most preferred institution.

Since the 1990's, many prison systems have moved toward the *privatization* of prisons. Privatization refers to the transfer of specific activities and responsibilities—such as providing work, health care, or training for inmates—to private agencies. In some cases, private agencies have taken over the running of entire prisons. The United Kingdom, Australia, and the United States have experimented with private prisons. Many people believe that this privatization will lead to increased efficiency. However, others question whether government should transfer the punishment of criminals to private hands.

Prisons today

Current problems. Severe overcrowding ranks as the major problem in most prisons. The overcrowding has developed because of new laws that require longer sentences, eliminate parole for certain crimes, and increase the number of crimes that require imprisonment.

Some judges in the United States have ruled that many prisons are so crowded that they violate prisoners' constitutional protection against "cruel and unusual punishments." Conditions have become so bad in some places that prisoners have been held in warehouses, tents, and house trailers. Many states have had to build more prisons or release inmates early to make room for new prisoners.

There are also concerns among health professionals and human rights groups regarding supermax prisons. In these prisons, inmates may be confined for up to 24 hours a day. Extreme social isolation of this kind can be emotionally and psychologically damaging, and inmates released from such an environment may be a great threat to society.

Prisons face other problems as well. A lack of adequate funding has made improvements difficult. In addition, tensions among prisoners and between prisoners and the prison staff often run high and lead to brutal attacks. Such conditions, worsened by overcrowding, have contributed to several prison riots since the late 1960's. In one of the most serious riots, 33 inmates and 10 prison staff members were killed in a rebellion at the Attica (New York) Correctional Facility in 1971.

Continuing debate. These current problems have brought attention to the continuing debate about the purposes and effectiveness of prisons. Studies have shown that even good rehabilitation programs fail to reform many released prisoners. The apparent failure of such programs has led many people to stress imprisonment as punishment rather than as treatment. On the other hand, experts also have failed to prove that prisons reduce the crime rate either by incapacitating offenders or by discouraging people from breaking the law. For this reason, some experts believe that it would be cheaper, more humane, and more productive to keep most offenders in community correctional centers rather than in prisons. They argue that only the most dangerous criminals should be imprisoned.

Some courts have experimented with sentences that allow criminals to remain out of prison. Some of these sentences impose house arrest enforced by electronic monitoring. Other sentences require criminals to hold a job, repay their victims, perform community service and receive counseling. James O. Finckenauer

Morris, Norval, and Rothman, D. J., eds. *The Oxford History of the Prison.* Oxford, 1995.

Prisoner of war is a captured member of a warring country's armed forces. In most cases, prisoners of war have surrendered to their enemy. But sometimes they have been taken by force. Prisoners of war are often called *POW's*.

In 1785, the United States and Prussia signed the world's first treaty calling for fair treatment for prisoners of war. The Hague Conventions of 1899 and 1907 and the Geneva Conventions of 1929 and 1949 established international rules dealing with the treatment of prisoners of war. Nearly all nations have agreed to follow these rules.

The Hague and Geneva conventions require that nations keep their prisoners of war in safe, sanitary camps. Representatives of nonfighting countries must be allowed to inspect the camps. These inspectors make certain that prisoners of war receive food, medical care,

and payment for work. The conventions also rule that nations must permit their prisoners to send and receive mail. Another regulation requires that countries return captured military doctors and chaplains to their own forces. The conventions provide that a prisoner need not give the enemy any information except the prisoner's name, rank, military serial number, and age.

In spite of the Geneva and Hague regulations, much mistreatment of prisoners of war has occurred. During World War II (1939-1945), Germany, Japan, and the Soviet Union treated their prisoners harshly. Millions of them died of cold, starvation, or mistreatment. During the Korean War (1950-1953), United Nations (UN) forces accused the Chinese and the North Koreans of *brainwashing* their prisoners (see **Brainwashing**). By the end of the Vietnam War (1957-1975), 651 American and thousands of North Vietnamese prisoners of war returned to their own countries.

After fighting ended in the Persian Gulf War in 1991, the United States and its allies began releasing the more than 60,000 Iraqis who had been taken prisoner. All 35 allied troops held by Iraq also regained their freedom.

Robert J. Pranger

Garrett, Richard. *P.O.W.* 1981. Reprint. Borgo Pr., 1989. A survey from the Hundred Years' War to Vietnam.

Prisons, Federal Bureau of, an agency of the United States Department of Justice, has responsibility for the custody and care of all prisoners of the federal government. Most of these prisoners have been sentenced. Others are awaiting trial or sentencing. Still others are illegal aliens who have been detained by the government.

The Bureau of Prisons operates dozens of facilities, including high-security penitentiaries, medium- and low-security correctional institutions, and minimum-security prison camps. It also has prison hospitals and other specialized facilities. Some federal prisoners are held in state, local, or private correctional institutions. The bureau pays for the support of these prisoners.

Critically reviewed by the Federal Bureau of Prisons

Privacy, Right of, is the right claimed by individuals to control the disclosure of personal information about themselves. It also covers people's freedom to make their own decisions about their private lives in the face of government attempts to regulate behavior.

The Constitution of the United States guarantees a number of privacy rights. The Fifth Amendment, for example, upholds the right to refuse to testify against oneself in a criminal case. The Fourth Amendment protects a person against unreasonable searches and seizures by government officials. The Supreme Court of the United States has ruled that the Constitution also protects privacy in certain matters relating to marriage, reproduction, birth control, family relationships, and child rearing and education.

Privacy is also protected by a branch of civil law called *tort law.* Under tort law, one person can sue another for violation of privacy in any of four categories: (1) disclosing private facts that are not newsworthy; (2) portraying a person in a false light; (3) using a person's image or personal facts for profit without the person's permission; and (4) intruding into a person's private physical space.

But federal law permits a number of activities that might be considered violations of privacy. For example, a person may intercept or record a conversation between two or more other persons with the consent of only one of those persons. Law enforcement officials, with a court order or other form of approval, may intercept calls without the consent of any party to the conversation. In most cases, employers may legally monitor employees' telephone conversations, electronic mail, and voice mail.

Computer systems enable many organizations, including government agencies, financial institutions, and health care providers, to collect information on a person without the individual's knowledge. Such information, as well as electronic mail and digital photographs of individuals, can be circulated worldwide on the vast computer network called the Internet.

Organizations collect information on individuals to investigate or prevent crime, to manage vast service programs, or to determine a person's eligibility for—or interest in—credit, insurance, education, or other services. Since the 1970's, however, Congress and the states have passed laws that restrict disclosure of personal information and give individuals the right to challenge the accuracy of information about themselves. These laws cover federal agencies, school records, credit reports, and telephone solicitation. In addition, the law holds that most privileged conversations with lawyers, spouses, clergy, and others are confidential. Robert Ellis Smith

Private school generally refers to any school that is not controlled by government authorities and is not supported chiefly by taxes or other public funds. A private school differs from a *public school,* which operates under public supervision with major support from government funds. Private schools are operated by religious groups and by independent nonreligious organizations seeking educational approaches not sufficiently represented in public schools.

Most private schools operate on a nonprofit basis, although a few are run as businesses to make money for their owners. Private schools are funded chiefly by tuition, grants from their sponsors, or contributions. Some private schools also have an *endowment*—that is, invested money whose income is used to fund the school.

In most countries, almost all schools were private until the early 1800's. At that time, many government leaders began to encourage development of public schools to foster national progress by making education widely available to citizens. Today, the number of public and private schools differs greatly from one country to another. In many developed countries, private schools offer popular alternatives to programs in public schools. Such alternatives include a general focus on preparation for college; a special focus on science, music, or other subject areas; and religious instruction. The Roman Catholic Church is one of the largest sponsors of private schools throughout the world. Other private schools are operated by Protestant, Jewish, and Islamic groups in

many countries. Arthur G. Powell

See also **Military school; Parochial school; Universities and colleges** (Kinds of universities and colleges).

Privateer, *PRY vuh TIHR,* is a privately owned armed vessel. Before the development of strong navies, many nations commissioned privately owned ships to assist them in time of war. Such commissions, first used in the 1400's, were known as *letters of marque and reprisal,* and ships and crews acting under them were called privateers. The privateers attacked merchant ships of the enemy nation and sank or robbed them. Unlike pirates, privateers operated with their government's permission.

Privateers helped the colonies against Britain in the Revolutionary War in America (1775-1783). On March 18, 1776, the Second Continental Congress authorized privateers. This action was taken after the British Parliament had prohibited all trade with the colonies and authorized seizure of their ships. George Washington was part owner of at least one privateer. Colonial privateers captured about 600 British ships.

From 1798 to 1801, the United States authorized privateers to seize French vessels, because many American ships were being taken by warships of republican France. In the War of 1812, American privateers seized 1,345 British ships. Some became pirates after the war. In 1856, the United States refused to sign the Treaty of Paris outlawing privateering because it feared it might need privateers to support its weak navy.

During the American Civil War (1861-1865), the Confederate government issued letters of marque. But after the first year of war, a volunteer naval system was substituted for privateering. The federal government tried privateering in 1863, and Chile used it against Spain in 1865. These were the last known instances of privateering. John W. Gordon

Privatization is the transfer of government programs, assets, or responsibilities to private individuals or organizations. There are many different types and degrees of privatization. In the purest form of privatization, a government would completely sell a state-owned business to private investors. In a less strict form of privatization, a government might hire private organizations to deliver public services. The opposite of privatization is the process of *nationalization,* by which a government increases its ownership of a country's industries and resources.

Many Western nations have privatized such functions as air travel and telephone service. Following the breakup of the Soviet Union in 1991, many former Soviet republics and Eastern European countries that had been dominated by the Soviet Union undertook large-scale privatization of their nationalized industries. Some other countries have hired private organizations to provide health care, airport management, and road construction.

When handled effectively, privatization can lower costs and increase flexibility in providing services. Privatization is not always successful, however. Some private buyers might lack the resources or expertise to manage public services effectively. Therefore, privatization efforts require careful planning and implementation to improve the chances for success. Donald F. Kettl

Privet, *PRIHV iht,* is the name of a group of flowering shrubs. The common privet is planted in many parks and gardens of North America. It is native to southern Europe and northern Africa. Other species of privets grow wild in Asia and Australia. All parts of privets are poisonous if eaten. The common privet is usually kept trimmed as a hedge but is sometimes cultivated as a large bush as much as 15 feet (4.5 meters) tall. Its white flowers are much smaller and less showy than those of the lilac, its close relative, but are similar in shape. Their odor is less sweet than that of the lilac. The common privet's smooth, dark-skinned fruit resembles a tiny olive. Some *cultivars* (varieties) have white, yellow, or greenish-yellow fruits. Fred T. Davies, Jr.

Scientific classification. Privets belong to the olive family, Oleaceae. The scientific name for the common privet is *Ligustrum vulgare.*

Privy Council, *PRIHV ee,* is an honorary council appointed by the Crown of the United Kingdom. Members of the Privy Council include Cabinet members, other political leaders, judges, and scholars. Privy councilors are selected from all countries in the British Commonwealth that recognize the British monarch as their symbolic head of state. The title of councilor is honorary in most cases. Council members become salaried officials only when given a place in the Cabinet. The lord president of the council is a member of the British Cabinet.

Council members serve during the life of the sovereign who appointed them, and for six months after the sovereign's death. The full council meets on rare occasions, such as the beginning of a reign, or when the reigning sovereign announces his or her marriage. The administrative work of the council is carried on through state departments. Each department is headed by a minister responsible to Parliament. The Judicial Committee is the highest judicial authority in the British Commonwealth. Members of the Privy Council use the title *Right Honourable* before their names, and letters *P.C.* (privy councilor) after their names.

The beginning of the Privy Council can be traced to the council of William the Conqueror. The council advised William the Conqueror on matters of state, and set the laws for the kingdom. The importance of the council declined as Parliament increased in power.

The British North America Act of 1867 established the King's (or Queen's) Privy Council for Canada. The Cabinet of the Dominion of Canada sits as a committee of the Canadian Privy Council. Arthur I. Cyr

Probability. When we say that one event is more probable than another, we mean it is more likely to happen. The branch of mathematics called *probability* tries to express in numbers statements of the form: An event *A* is more (or less) probable than an event *B.*

If a person tosses a coin, there are only two ways it can fall—heads or tails. It is as likely to fall one way as the other. Thus we say that the probability of throwing heads is $\frac{1}{2}$. If the coin is tossed 100 times and x is the number of times heads occurs, we can expect the ratio $\frac{x}{100}$ to be close to $\frac{1}{2}$. More generally, if a coin is tossed n times and x is the number of times heads occurs, the ratio x/n will be very close to $\frac{1}{2}$ if n is very large.

Now suppose a person tosses three coins. There are eight possible outcomes: *hhh, hht, hth, thh, htt, tht, tth,* and *ttt. Three* of these outcomes have two heads, so the probability of throwing two heads is $\frac{3}{8}$. Only *one* outcome has exactly three heads, so the probability of

throwing three heads is $\frac{1}{8}$. The event *two heads* is more probable than the event *three heads.* If a set of three coins is tossed a very large number of times, we would expect two heads to occur very nearly $\frac{3}{8}$ of the time and three heads to occur very nearly $\frac{1}{8}$ of the time.

Probability is the foundation of the science of statistics. A political scientist, for example, may gather data and use statistics to predict the percentage of voters who will vote for a particular candidate in an election. The political scientist then uses probability to calculate the possible error of the estimate. Thomas J. Brieske

Probate. When people die, their wills must be *probated* (proved to be genuine). A deceased person's executors bring the will before a court where wills and estates are handled. This court is usually called the *probate court.* The executors present the will and show proof that it is the true will of the deceased. A will should be offered for probate soon after the death of the person who made it, called the *testator.* After the will is presented, the court usually issues a notice to the testator's heirs who would have shared the property if no will had been made. A hearing is then held in the court, and the heirs are given a chance to object to the will. The judge then decides if the will is genuine. In many states, a jury makes this decision.

A will may be denied probate if the testator lacked mental capacity or was subjected to undue influence. If all requirements have been met, the will is approved, and the executors carry out its provisions.

William M. McGovern

See also **Executor; Will.**

Probation is a judicial act that allows a convicted criminal to remain free in society instead of serving a sentence in prison. Probation is most frequently granted by a judge to juveniles or to people who have been convicted of an offense other than the most serious crimes, such as armed robbery, murder, or rape. Probation gives such people a chance to prove that they will not repeat their crime. The word *probation* comes from the Latin word for *prove* or *test.*

Many criminologists believe that probation encourages good conduct by the *probationer* (person on probation). Probation enables the offender to avoid the harmful effects of being imprisoned with experienced criminals. It also costs the taxpayers less than imprisonment because a probationer does not have to be fed, clothed, housed, and guarded in a jail.

When a judge decides to grant probation, he or she places the offender under the supervision of a court official called a *probation officer.* The judge also sets the period of probation, which can range from six months to five or more years. During this time, the probationer must follow certain rules of conduct called *conditions of probation.* The probationer also must meet regularly with a probation officer to discuss any problems or other matters connected with the case.

At the end of the probation period—if the probationer has avoided getting into trouble—the trial judge releases the probationer from all supervision. But if the conditions of probation have been violated during the probation period, the probation officer may report the violations to the judge. The judge may send the probationer to prison for the original crime if the wrongdoer has violated any of the conditions of probation.

Probation differs from *parole* and *pardon.* Parole is the release of a convict who has served part of a sentence. A pardon excuses a person from any punishment for a crime. Charles F. Wellford

Problem solving. See **Education** (How people learn); **Science** (How scientists work).

Proboscis monkey, *proh BAHS ihs,* is a large, leaf-eating monkey that lives on the island of Borneo in Southeast Asia. It gets its name from its *proboscis* (long nose). A male weighs up to 52 pounds (24 kilograms), and a female weighs up to 26 pounds (12 kilograms). These monkeys are from about 21 to 30 inches (53 to 76 centimeters) long, not including the tail.

Adult proboscis monkeys have reddish hair on their heads, backs, shoulders, and thighs, and pale gray hair on the arms and legs. Infant monkeys are born with silver-blue fur that turns gray after about three months. Proboscis monkeys have sharp back teeth that enable them to shred leaves easily. They have a well-developed thumb adapted to picking leaves and other plant parts. These monkeys live in trees near rivers. They feed mainly on leaves and also eat fruits and flowers.

© Gunter Ziesler, Bruce Coleman Ltd.

The proboscis monkey gets its name from its *proboscis,* or long nose. An adult proboscis monkey, such as the one pictured here, has reddish hair on its head, back, shoulders, and thighs.

Proboscis monkeys are good swimmers. Crocodiles prey on them in rivers and streams. But clearing of trees in their environment for agricultural purposes is the main threat to the animal's existence. Randall L. Susman

Scientific classification. The proboscis monkey belongs to the Old World monkey family, Cercopithecidae. Its scientific name is *Nasalis larvatus.*

See also **Monkey** (picture).

Procaine, *PROH kayn,* is a drug used to block pain sensation in a specific part of the body. Such drugs are called *local anesthetics.* Doctors use injections of procaine to produce *regional nerve blocks* and *spinal anesthesia* (see **Anesthesia** [Local anesthesia]). It is often called by the trade name *Novocain.* Procaine is a white,

crystalline powder. It is chemically similar to the local anesthetics benzocaine and cocaine. But, unlike those anesthetics, it does not produce anesthesia when applied to the surface of the skin or mucous membranes.

A German chemist, Alferd Einhorn, first synthesized procaine in 1905. It soon replaced cocaine as the drug of choice for regional nerve block anesthesia, and for many years, it served as the standard to which other local anesthetics were compared. The use of procaine has declined since the introduction of the local anesthetic lidocaine in the 1940's. Edwin S. Munson

See also **Benzocaine; Cocaine; Lidocaine.**

Proclamation is an executive notice issued under the authority of the head of a state or country. It announces some order or regulation that is important to the people. A proclamation that grants a pardon to rebels is a *proclamation of amnesty.* Usually a proclamation appears in printed form. See also **Emancipation Proclamation.** Sherman L. Cohn

Proclamation of 1763. See **Revolutionary War in America** (The Proclamation of 1763).

Producer. See **Motion picture** (How motion pictures are made); **Theater** (The producer).

Product liability suit is a legal action brought against a business accused of placing a defective or unreasonably dangerous product on the market. In most cases, the plaintiff claims to have been harmed by a product made or sold by the defendant. Product liability may be based on manufacturing or design flaws, or on *informational defects.* Informational defects include inadequate warnings or instructions for use. Product liability is usually limited to products sold or leased as new.

To win a product liability suit, the plaintiff generally must prove that a product's defective or unreasonably dangerous condition caused personal injury, death, or property damage. If a suit is successful, the plaintiff may receive payment for medical expenses, lost earnings, pain and suffering, disability, *disfigurement* (damaged appearance), or property damage. Many companies carry insurance to protect against product liability suits.

In the United States, liability for defective products may be based on (1) *strict liability,* (2) *negligence,* or (3) *breach of warranty.* A court can impose strict liability on a company if it manufactured or distributed a product that was defective when it left the company's control. In some cases, the plaintiff does not have to prove that the defendant knew or should have known about the defect.

Negligence, in product liability suits, means the defendant carelessly caused the defect or failed to discover it. The plaintiff's own negligence or other fault may reduce or eliminate the defendant's liability.

Breach of warranty means that the product was sold with a defect that violated existing quality or safety provisions. In the United States, breach of warranty claims are based on the Uniform Commercial Code. This code, a body of laws governing buying and selling of goods, has been adopted in whole or part by all the states.

Product liability rules are almost entirely established by the states. Although such laws are similar throughout the United States, there is some variation from state to state. Edward J. Kionka

Production is a major step in the series of economic processes that bring goods and services to people. Other main steps include *distribution* (getting the goods to persons who use them) and *consumption* (the final use of the goods). For example, the producers of a loaf of bread include the people who raise the grain, those who make flour, and those who bake the loaves. The bakery salespeople and the truck drivers who deliver the bread are distributors. Consumers buy and eat the bread. In a balanced economy, production and consumption are about equal and goods flow smoothly from maker to user.

A balanced economy is one in which the vast majority of people who want to work have jobs, and the total amount of production is sufficient to satisfy the needs and wants of the people. When a lack of balance exists, some blame can be placed on consumption, because many persons do not have money to buy goods they want. Other factors, such as technological change, overextension of credit, and improper distribution of goods can unbalance the economy. Daniel Quinn Mills

See also **Consumption; Economics; Factory; Marketing; Mass production; National income.**

Productivity refers to the ability to create goods and services by using available resources, including labor, equipment, and land and other natural resources. Economists frequently measure the productivity of a nation's economy. Their findings often are expressed as the amount of goods and services an average worker can produce over a given period.

A rise in productivity may result from better production methods, more equipment, and higher levels of education among workers. Over long periods, productivity growth can bring dramatic increases in a country's standard of living. For example, before the 1600's, it took as much as 90 percent of a country's workers to produce food for everyone. Today, only about 3 percent of all workers in industrialized countries work in agriculture. As a result, more people have become available to produce other goods and services. Increased productivity can also lower the cost of creating goods and the prices consumers must pay for them. Shelby Gerking

See also **Industry** (Labor productivity); **Wages and hours** (Wages).

Profit is the amount of money a company has left over from the sale of its products after it has paid for all the expenses of production. These expenses include costs of such things as raw materials, workers' salaries, and machinery. They also include a reasonable return on the owner's investment, a salary for the labor the owner supplies to the firm, and other costs that are hard to calculate. A main task of accounting is to define and measure profits accurately.

Profits are vital to the economic system of the United States, Canada, and other countries where private enterprise is encouraged. In such countries, profits belong to the owners of companies or the stockholders of corporations. One of the chief reasons for operating a business is to make a profit. The desire for profits motivates companies to produce their goods efficiently. This is because the lower a company's costs are, the greater its profits can be.

A business can earn a profit only by producing goods and services whose selling price is greater than the cost of production. Therefore, business executives seek to use labor and raw materials to produce and sell things

for which customers will pay a price that is greater than the cost of production. Thus, the search for profits is also the search for the uses of a country's labor and raw materials that will satisfy consumers most completely.

Some business executives constantly lower prices to capture sales and profits from their competitors. But there are several reasons why competition does not eliminate profits. For one thing, at any one time, there will be many firms that have discovered profitable opportunities their competitors cannot yet match. Sometimes, new firms cannot duplicate a profitable product because of patents or trademarks, or for other reasons. Sometimes, new firms cannot produce goods as cheaply as established ones. In addition, the bother and risk of entering an unfamiliar industry keeps some new firms from competing with a product that is not especially profitable. Established firms can then enjoy reasonable profits without fear of new competition. Henry J. Aaron

See also **Capitalism** (Capitalism in its ideal form); **Price; Accounting; Business; Corporation.**

Profit sharing. Many employers share part of their profits with their employees. They do this to encourage productive work and to induce the employees to remain with the company.

Profit-sharing plans are usually based on the net profit of the firm, after all interest, taxes, and other charges against the gross profits have been paid. A certain percentage of the profit is set aside for the employees, and workers share in it according to their salary or their length of service with the company.

Some industrialists object to profit-sharing plans, because workers do not share the responsibilities and risks of the business. Some labor leaders also oppose such plans, believing that workers should concentrate their efforts on obtaining higher wages. But other industrialists and labor leaders believe that properly administered profit-sharing plans promote better understanding between employer and employees, and stimulate efficiency, since both employer and employees share in any gains achieved by joint effort. Daniel Quinn Mills

Progeria, *proh JIHR ee uh,* is an extremely rare disorder that causes premature aging in children. The disease is also called *Hutchinson-Gilford syndrome.* It was first described in 1886 by Sir Jonathan Hutchinson, an English physician. Since then, only about 100 cases have been reported worldwide. The disease occurs only once in every 4 million births. The word *progeria* comes from a Greek word that means *prematurely old.*

Most people with progeria appear normal at birth, but they soon begin to grow more slowly than normal. By 1 or 2 years of age, their hair turns lighter in color and starts to fall out. By age 3 or 4, they are almost bald. In addition, their skin becomes thin, wrinkled, and spotted, their bodies take on a stooped appearance, and their facial features look "pinched." Their heads appear unusually large and veiny.

Many people with progeria develop disorders of the circulatory system, especially high blood pressure, heart disease, and stroke. Some victims die as early as 7 years of age. About half die by age 13. The oldest known person with progeria lived 27 years.

The disease does not affect a person's mental development. Many people with progeria are highly intelligent. Most victims are very shy because of their physical appearance. Although people who have progeria continue to grow slowly, few reach a height of 3 feet 6 inches (107 centimeters) or a weight of 40 pounds (18 kilograms).

Scientists do not know the cause of progeria, and there is no effective treatment. The rareness of the disease makes it difficult to study. F. L. DeBusk

Progesterone, *proh JEHS tuh rohn,* is a hormone produced mainly by the ovaries and the placenta in female animals during the period when they are able to bear young. Small amounts are also produced by the adrenal glands in both females and males and by the testes in males.

Progesterone plays an important role in preparing a woman's uterus for pregnancy. About midway through a woman's monthly menstrual cycle, one of her two ovaries releases an egg. This process, called *ovulation,* causes changes in the ovary so that it releases high levels of progesterone into the blood for 10 to 12 days. Progesterone stimulates the lining of the uterus so that the egg, if it has been fertilized, may attach to the uterine wall. If pregnancy does not occur, the ovary stops producing high levels of progesterone. The uterine lining then breaks down and passes out of the body during menstruation. See **Menstruation.**

The monthly increase of progesterone in a woman's blood after ovulation causes cyclic changes in other body functions. For example, the woman's body temperature increases, and her breasts may enlarge or become especially sensitive. During pregnancy, the placenta produces large amounts of progesterone. The high progesterone level keeps the uterine muscle relaxed so the baby is not born too soon. See **Placenta.**

Physicians use progesterone as a drug to treat disorders of the reproductive system. These disorders include premenstrual tension and irregular menstruation. Synthetic forms of progesterone are used alone and in combination with synthetic estrogens in birth control pills. P. Landis Keyes

Progression, in mathematics, is a sequence of related numbers or symbols called *terms.* The following examples illustrate three common kinds of progressions:

Arithmetic progression: 1,2,3,4,5,6, ... and so on;
Geometric progression: 2,4,8,16,32, ... and so on;
Harmonic progression: $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{6}$, $\frac{1}{8}$, ... and so on.

In each of these progressions, the terms after the first are formed in different ways. Each term of an arithmetic progression is formed by *adding* a quantity called the *common difference* to the previous term. In the example, the common difference is 1. Each term of a geometric progression is formed by *multiplying* the previous term by a quantity called the *common ratio.* In the example, the common ratio is 2. Each term of a harmonic progression is a fraction. The numerators are all 1's, and the denominators are formed like the terms of an arithmetic progression. In the example, the common difference of the denominators is 2.

Progressions are useful in solving many problems in science and business. For example, they simplify the cal-

culation of compound interest (see **Interest**). Mathematicians have developed formulas for finding the value of any term of a progression and for finding the sum of any number of terms.

Arithmetic progressions may have various first terms and common differences, as shown below:

	First term	Common difference	Arithmetic progression
A	2	3	2, 5, 8, 11, 14, 17, ...
B	3	−2	3, 1, −1, −3, −5, ...
C	1	$\frac{1}{2}$	1, 1 $\frac{1}{2}$, 2, 2 $\frac{1}{2}$, 3, ...
D	*a*	*d*	*a, a + d, a + 2d, a + 3d, ...*

In example A, the 4th term (11) is equal to 2 + 3 + 3 + 3, which can also be written 2 + (4 − 1)3. The value of *any* term can be found by adding to the first term the product of the common difference times one less than the number of the term. In general, *a* can be used to represent the first term, and *d* the common difference. The formula for the *n*th term (U_n) is

$$U_n = a+(n-1)d$$

The sum of the first 6 terms of example A is 2 + 5 + 8+11+14+17 = 57. Note that the sum of the first and last terms (2,17) is 19. Likewise, the sums of the 2nd and 5th terms (5,14) and the 3rd and 4th terms (8,11) are also 19. The sum of all 6 terms (57) is equal to 3 times 19, or 3 times the sum of the first and last terms. In general, the sum of any number of terms of an arithmetic progression is one-half the number of terms times the sum of the first and last terms. If we use the symbol *Sn* to represent the sum, the formula is

$$S_n = \frac{n}{2}(a + U_n)$$

Geometric progressions may have various first terms and common ratios, as shown below:

	First term	Common ratio	Geometric progression
A	2	3	2, 6, 18, 54, 162, ...
B	1	$\frac{1}{2}$	1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, ...
C	a	r	a, ar, ar^2, ar^3, ... ar^{n-1}, ...

Example C indicates that the value of the *n*th term (*Un*) is ar^{n-1}. The exponent ($n - 1$) means that *r* is to be used as a factor ($n - 1$) times. Using this formula, the 6th term in example A can be calculated:

$$U_6 = 2(3)^5 = 2\times3\times3\times3\times3\times3 = 486$$

The sum of *n* terms can be calculated by the formula

$$S_n = \frac{a-ar^n}{1-r}$$

For example, the sum of the first 4 terms of example A is calculated as follows:

$$S_n = \frac{2-2(3)^4}{1-3} = \frac{2-162}{-2} = 80$$

If *r* is less than 1, the sum of an *infinite* number of terms approaches the limit $a/(1 - r)$. See **Series** (Working with infinite series). Jeffrey C. Barnett

Progressive Conservative Party is the oldest political party in Canada. Until 1942, its name was simply the Conservative Party. Many people still refer to the party by that name. In general, the Conservatives favor tax reform, elimination of the national debt, and tight controls on government spending. Business and professional interests have traditionally supported the party.

The Conservative Party dates back to the 1850's. It grew out of an alliance of conservatives, reformers, and moderates who favored the confederation of British colonies in North America. John A. Macdonald of Upper Canada (later Ontario) was the party's first leader.

After confederation in 1867, the Conservatives gained control of the new country's government. Except for a period of Liberal Party control from 1873 to 1878, the Conservatives held power until 1896. Macdonald served as prime minister from 1867 to 1873 and from 1878 until his death in 1891. Under him, Canada's first transcontinental railroad was built. Macdonald also supported high tariffs in an effort to boost Canadian manufacturing.

The Conservatives lost power to the Liberals in 1896, but they regained control of the government in 1911, when Robert L. Borden became prime minister. In 1917, during World War I, Borden's government began to *conscript* (draft) men for military service. Conscription was highly unpopular in the French-speaking parts of Canada. It cost the Conservatives support in those areas for many years. Borden resigned as prime minister in 1920. Except for three months of Conservative control in 1926, the Liberals held power from 1921 to 1930.

Richard B. Bennett led the Conservatives to victory in 1930. He failed to strengthen the Canadian economy during the Great Depression. But his government established Canada's central bank and the nation's publicly owned broadcasting system. The Liberals defeated the Conservatives in the election of 1935.

The Conservative Party changed its name to the Progressive Conservative Party in 1942. The renamed party did not win a national election until 1957, when John G. Diefenbaker was party leader. As prime minister, Diefenbaker refused to accept atomic warheads for defense missiles supplied to Canada by the United States. He also failed to curb high unemployment in Canada. The Conservatives were voted out of office in 1963.

Brian Mulroney led the party to an overwhelming victory in 1984. His efforts to amend Canada's constitution to satisfy Quebec nationalists failed, and many of his economic proposals proved unpopular. But he signed a free-trade agreement with the United States in 1988.

Mulroney resigned in early 1993. The Conservatives won only two legislative seats in an election later that year. Since then, the party has never won more than a handful of seats. J. L. Granatstein

Progressive education was a revolt against the traditional schools of the United States of the 1800's. It grew from the belief that schools had failed to keep pace with rapid changes in American life.

The traditional school stressed specific subjects—reading, writing, arithmetic, geography, history, and grammar. The teacher lectured or dictated a lesson, and the students copied it in their notebooks. The students then learned by heart what was in their notebooks and recited what they learned from their textbooks. The teacher enforced order and quiet except for recitation periods. Students sat at rows of desks fastened to the floor, and they could not move or talk without permission.

Progressive educators thought that traditional education should be reformed. Famous progressive educators of the 1800's included Francis Parker and G. Stanley

Elsie Ripley Clapp Papers, Special Collections/Morris Library, Southern Illinois University

Learning by doing real tasks was a major educational technique used in progressive education. In this picture, children in a progressive school of the 1930's are building their own village.

Hall. In the early 1900's, John Dewey became a well-known spokesman for progressive education. See **Parker, Francis W.; Hall, G. Stanley; Dewey, John.**

Progressive educators tried to reform elementary school methods in several ways. They thought teachers should pay more attention to the individual child and not treat all children alike. Progressive educators believed children learn best when they are genuinely interested in the material, and not when they are forced to memorize facts that seem useless to them. Children should learn by direct contact with things, places, and people, as well as by reading and hearing about them. Thus, elementary schools should include science laboratories, workshops, art studios, kitchens, gymnasiums, and gardens. Progressive educators believed this procedure would develop the child's physical, social, and emotional nature as well as its mind.

In addition, progressive educators stressed greater freedom, activity, and informality in the classroom. They believed that children learn better when they can move about and work at their own pace. They thought children should gather materials from many sources rather than from just one textbook, and should work together in groups. Discussion, dramatics, music, and art activities became a larger part of classroom procedures.

Progressive education spread most widely through the elementary school level. Teachers planned individual instruction and centered it around projects, units, or activities rather than the usual courses or subjects. They taught students of different abilities in separate groups.

Criticism of progressive education. Many writers and some educators began increasingly to criticize progressive education during the 1940's and 1950's. They charged students did not learn fundamental subjects well enough. Other educators said that students learned as well under progressive education as under traditional methods. But by the early 1960's, many schools had begun to experiment with different teaching methods. Many experiments used "progressive" principles but did not use the term. Douglas Sloan

Progressive movement was a campaign for economic, political, and social reform in the United States. It began during a nationwide depression that lasted from 1893 until about 1897. The movement ended when the United States entered World War I in 1917. Americans turned their attention from reform to war.

Industry in the United States had grown swiftly during the 1800's. This change caused such problems as business monopolies, dishonest politics, city slums, and poor working conditions in factories and mines. In the 1890's and early 1900's, many reformers helped bring about laws aimed at relieving these problems. They began to call themselves *progressives* about 1905. They had their greatest effect at the local and state levels, where the movement began. But the U.S. Congress also adopted some key measures.

Economic reforms of the progressive movement included increased government regulation of business

University of Illinois at Chicago, University Library/Special Collections

Progressive movement reforms included efforts to improve the lives of poor people. This photograph shows a kindergarten at Hull House, a settlement house in Chicago that was a famous center of the progressive movement. Hull House was founded in 1889 by Jane Addams and Ellen Starr.

and a series of tax reforms. In 1890, Congress passed the Sherman Antitrust Act, which banned industrial monopolies that limited competition. But the act had little immediate effect, partly because its wording was vague. Progressives worked for a stronger law to prevent business abuses. In 1914, Congress set up the Federal Trade Commission to stop illegal business practices.

Before the progressive movement, many taxes had been based on property. But many wealthy people hid such property as stocks and bonds from the government and did not pay taxes on them. Largely for this reason, progressives demanded that taxes be based on income rather than on property. In 1911, Wisconsin passed the first effective state income tax law. Two years later, Congress enacted what became the first permanent federal income tax in the United States.

Political reforms. Many city and state governments were controlled by dishonest business executives and politicians who attempted to block economic reforms. But in the 1890's and early 1900's, progressive mayors gained office in a number of cities. These mayors, including Tom L. Johnson of Cleveland and Samuel M. Jones of Toledo, Ohio, worked to end corruption in law enforcement, public transportation, and other city services. Progressives also worked to increase the political power of the voters. In 1903, Los Angeles became the first city to approve *recall,* which allowed voters to remove a person from public office before his or her term ended.

State governments also adopted political reforms. A number of states granted *home rule,* the right of a city to govern itself. In 1898, South Dakota passed the first state *initiative* and *referendum* laws. Under the initiative, voters could pass laws without the need for the state legislature's approval. The referendum enabled voters to overrule laws adopted by the legislature. Wisconsin, led by Governor Robert M. La Follette, adopted the first effective state *direct primary law* in 1904. This law allowed the voters to nominate candidates. Previously, each political party had held a convention at which delegates nominated candidates.

Political reforms on the federal level included the 17th Amendment to the Constitution. This amendment, adopted in 1913, provided for United States senators to be directly elected by the people. The state legislatures had previously elected U.S. senators.

Social reforms of the progressive movement included improvements in the living and working conditions of the poor. Many states passed housing regulations to help relieve crowded city slums. In some slums, progressives set up centers called *settlement houses.* Reformers and slum residents met in them and worked to improve slum conditions. One famous settlement house was Hull House, founded in 1889 by Jane Addams and Ellen Starr, two Chicago social workers.

In many factories and mines, employees worked long hours for low wages and operated unsafe machinery. Progressives helped bring about state laws that required safety precautions in factories and allowed workers to collect money for injuries suffered on the job. Some states also set a minimum wage.

In the early 1900's, writers called *muckrakers* exposed many social and political injustices in the nation. Their works helped bring about many reforms. Leading muckrakers included Jacob Riis, Upton Sinclair, Lincoln Steffens, and Ida Tarbell. Each of these writers has a separate biography in *World Book.*

In spite of their achievements, progressives failed to significantly curb the power of large businesses. However, they exposed injustices and created the patterns of reform that became the basis for reform movements later in the 1900's. David P. Thelen

Mattson, Kevin. *Creating a Democratic Public: The Struggle for Urban Participatory Democracy During the Progressive Era.* Penn. State Univ. Pr., 1998.

Progressive Party is a name given to several political parties that have been organized in the United States. In general, the Progressives stood for liberal social, political, and economic reform.

The "Bull Moose" Party. Shortly after the renomination of William Howard Taft in 1912, a group of Republicans left their party to found a new group called the *Progressive Party.* It was nicknamed the "Bull Moose" Party. The Progressives nominated Theodore Roosevelt and Hiram Johnson for president and vice president. They polled more votes in the election than the Republicans, but not as many as the Democrats. The Progressives nominated Roosevelt for president again in 1916 but he refused to run, and most of the Progressive leaders went back to the Republican Party.

The La Follette Progressives. In 1924, a group of farm, labor, and religious leaders formed a new Progressive movement. Senators Robert M. La Follette and Burton K. Wheeler were nominated to run for president and vice president. The Progressives polled nearly 5 million votes, but carried only La Follette's home state, Wisconsin. Robert La Follette's sons, Governor Philip La Follette and Senator Robert M. La Follette, Jr., led the Wisconsin Progressive Party, which had considerable success from 1934 to 1938. In the 1940's, it lost strength. The Progressives voted to merge with the Republicans in 1946.

The Progressive Party of 1948 was formed by various left-wing groups, including the Communists. Henry A. Wallace, former Democratic vice president of the United States, was the party's unsuccessful candidate for president in the 1948 election. Donald R. McCoy

Prohibition, *PROH uh BIHSH uhn,* refers to laws that are designed to prevent the drinking of alcoholic beverages. The laws forbid the manufacture, sale, or transportation of such beverages. Alcoholic beverages include beer, gin, rum, vodka, whiskey, and wine.

In the United States, prohibition became so popular in the early 1900's that, in 1920, a prohibition amendment was added to the U.S. Constitution. This amendment, the 18th Amendment, caused the use of alcoholic beverages to decline sharply. However, many people ignored the national ban and drank illegal beverages supplied by networks of bootleggers. The 18th Amendment

was abolished in 1933. It is the only amendment to the U.S. Constitution that has ever been repealed. Canada, Finland, and Norway also outlawed intoxicating beverages during the early 1900's.

Prohibition in the United States

The movement toward prohibition. In the 1600's and 1700's, the American colonists drank large quantities of beer, rum, wine, and hard cider. Such alcoholic beverages were often safer to drink than impure water or unpasteurized milk and were less expensive than coffee or tea. By the 1820's, people in the United States were drinking, on the average, the equivalent of 7 gallons (26 liters) of pure alcohol per person each year. This amount of alcohol is in about 70 gallons (260 liters) of beer, 39 gallons (148 liters) of wine, or $15\frac{1}{2}$ gallons (58.7 liters) of distilled liquor.

Some people, including physicians and ministers, became concerned about the extent of alcohol use. They believed that drinking alcohol damaged people's health and moral behavior, and promoted poverty. People concerned about alcohol use urged *temperance*—that is, the reduction or elimination of the use of alcoholic beverages.

At first, supporters of temperance urged drinkers to drink only moderate amounts. But the supporters later became convinced that all alcoholic beverages were addictive. As a result, they tried to end the use of alcohol. In the 1820's and 1830's, the first temperance crusade reduced the average annual intake of pure alcohol per person to about 3 gallons (11 liters). During the 1850's, about a dozen states passed prohibition laws, led by Maine in 1851.

Support for prohibition declined after the Civil War began in 1861. To revive support, people who favored prohibition, often called *drys* or *prohibitionists,* formed a number of organizations to promote liquor reform. In 1869, for example, drys founded the Prohibition Party, which presented prohibitionist candidates for political office. In 1874, a group of Protestant women established the Woman's Christian Temperance Union (WCTU). Drys organized the Anti-Saloon League in 1895.

From about 1900 to 1920, numerous economic, political, and social reforms were carried out in the United States. During this period, many reformers supported national prohibition, and they did so for a variety of reasons. Social reformers blamed alcohol for poverty, health problems, and the neglect by husbands of their wives and children. Political reformers saw saloons as the backbone of corrupt urban political organizations. Employers felt that drunkenness reduced their workers' safety and productivity.

During the early 1900's, some people felt that the large numbers of recent immigrants to the United States would become more "American" if their drinking habits were changed. Many religious denominations taught that drinking alcohol was immoral.

Between 1880 and the beginning of World War I in 1914, many states adopted either statewide prohibition or *local-option laws.* Local-option laws gave individual communities the right to ban the sale of alcohol. In 1913, Congress passed the Webb-Kenyon Act, which forbade the mailing or shipping of liquor into any state that banned such shipments. That same year, drys began calling for a prohibition amendment to the Constitution.

United Press Int.

Government agents seized enormous quantities of illegal beer and liquor during the Prohibition Era. Underworld gangs made millions of dollars from the sale of such alcoholic beverages. Agents dumped much beer into Lake Michigan, *above.*

When the United States entered World War I in 1917, most Americans considered prohibition an appropriate patriotic sacrifice. In December 1917, the U.S. Congress approved the 18th Amendment to the Constitution. This amendment prohibited the manufacture, sale, transportation, import, and export of "intoxicating liquors." It was ratified by the states in January 1919. In October 1919, Congress adopted the Volstead Act. This law provided for the enforcement of the 18th Amendment and defined *intoxicating liquors* as those containing at least 0.5 per cent alcohol. The 18th Amendment went into effect in 1920 with widespread support.

Life during prohibition. Although national prohibition did not eliminate the drinking of alcoholic beverages, it did sharply reduce their use. Purchasing liquor was not only against the law, but it was also very expensive. However, a large minority of Americans continued to drink alcohol. Drinking wine, beer, and other alcoholic beverages had been a traditional part of the cultures of many recent immigrants to the United States, including Irish, Italians, Jews, and Poles. In addition, numerous urban middle- and upper-class Americans considered drinking sophisticated and sociable.

During prohibition, many people made their own beer, wine, or distilled liquor at home illegally. Also, numerous people bought alcoholic drinks in illegal bars called *speakeasies.* Many physicians gave their patients prescriptions for legal "medicinal" wine or liquor.

Bootleggers met much of the demand for illegal alcoholic beverages. Most bootleggers were young immigrant men. The liquor trade was highly profitable, and bootleggers battled each other for control of liquor supplies and markets. Violent gang wars erupted in many large cities, and gang members killed one another at a furious pace. Al Capone of Chicago was probably the era's most famous bootlegger.

During the late 1920's, more than 1 million gallons (3.8 million liters) of liquor was smuggled into the United States each year from Canada. Liquor also was smuggled into the country from ships located just beyond U.S. waters in the Atlantic or Pacific oceans or in the Car-

ibbean Sea. In addition, alcoholic beverages were made from alcohol that was legally produced in the United States for use in manufacturing. Neither federal agents nor state and local officials could stop the widespread violation of national prohibition.

The decline of the prohibition movement. Antiprohibitionists opposed prohibition for a number of reasons. They argued that the ban on alcohol encouraged crime and disrespect for the law. They also claimed that prohibition gave the government too much power over people's personal lives. Recent immigrants to the United States saw prohibition as an attack on their cultural traditions. After the Great Depression began in 1929, many people argued that prohibition took away jobs and deprived the government of badly needed revenues from taxes on liquor.

In the 1932 presidential campaign, the Democratic Party endorsed the repeal of prohibition, and the Democratic presidential candidate, Franklin Delano Roosevelt, won the election by a large margin. In February 1933, Congress proposed the 21st Amendment to the Constitution to repeal the 18th Amendment. The states quickly ratified the 21st Amendment, and national prohibition ended on Dec. 5, 1933.

A few states, mainly ones in the South, retained prohibition until the 1950's or 1960's. In 1966, Mississippi became the last state to repeal statewide prohibition. Since then, most efforts to forbid the use of alcohol by adults have been abandoned. Attention has shifted instead to the treatment of alcoholism and to the solution of other alcohol-related problems.

Prohibition in Canada

A strong temperance movement arose in Canada during the 1840's and 1850's. Many communities adopted local-option laws after the Canada Temperance Act permitted such laws in 1878. In 1898, a national *referendum* (direct vote) showed that a majority of voters outside Quebec favored national prohibition.

After World War I began in 1914, support for prohibition increased in Canada. In 1918, the Canadian government passed a law that banned the manufacture and importation of all alcoholic beverages until a year after the war ended. By 1918, every Canadian province except Quebec had adopted a permanent prohibition law. After World War I ended in 1918, opposition to prohibition increased in Canada. This rising opposition was due in part to a desire to profit from the smuggling of alcoholic beverages to people living under prohibition in the United States. Between 1921 and 1948, all of the Canadian provinces repealed their prohibition laws.

Hintz, Martin. *Farewell, John Barleycorn: Prohibition in the United States.* Lerner, 1996. Younger readers.

Prohibition Party is a political organization of the United States. Its major purpose is to prevent the use of alcoholic beverages in the country. The party was organized in 1869. It began immediately to present candidates for state and local elections. In 1872, it nominated candidates for president and vice president.

The Prohibition Party reached its greatest strength in 1892, when 271,000 votes were cast for its candidates. The party has declined in strength since then. In 1984, about 4,000 people voted the Prohibition ticket. From 1977 to 1980, the party used the name *National Statesman Party.* The party has worked closely with the American Council on Alcohol Problems, formerly the Anti-Saloon League. Their greatest triumph was passage of the 18th Amendment to the Constitution. This amendment prohibited the production, sale, transportation, import, and export of intoxicants. Donald R. McCoy

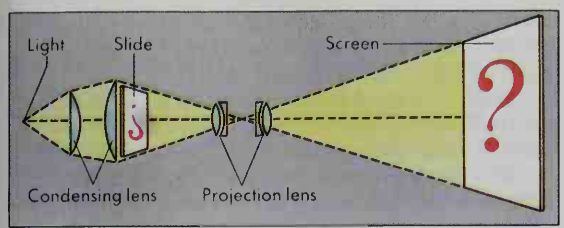
Projectile. See Ballistics.

Projection screen is a square or rectangular device on which motion pictures or slides are shown. A screen reflects an enlarged image of the projected movie or slide so that many people can view it at one time.



Most projection screens are made of fabric. They vary greatly in size. This article discusses the small portable screens that are used in such places as homes, schools, and libraries. For information on the large, permanently mounted screens that are used in motion-picture theaters, see Motion picture (How motion pictures work [The screen]).

Most portable screens measure from 30 by 40 inches (76 by 100 centimeters) to 60 by 60 inches (150 by 150 centimeters). Screens are classified by their surface. *Glass-beaded* screens have tiny beads on the surface that provide a bright image when viewed from the center of a room. *Lenticular* screens have thin, lens-shaped ridges on the surface and provide a sharp, bright image regardless of viewing angle. *Matte* screens are dull white and provide sharpness and a wide viewing angle. However, they provide less brightness than glass-beaded or lenticular screens. Robert A. Sobieszek

Projector is a device used to show pictures on a screen. One common type is a machine for showing photographic slides. The simplest projector consists of (1) a light, (2) a reflector that focuses light rays, (3) a *condensing* (focusing) lens, and (4) a projection lens.

A powerful light is needed to show pictures on a screen. A projector uses an *incandescent* bulb that glows with heat. Some projectors use bulbs as strong as 1,000 watts. The reflector, located behind the bulb, is a *concave* (inward curving) mirror. Light rays striking it reflect back through the bulb. These rays and rays coming directly from the bulb then enter a thick *plano-convex* lens, which is flat on one side and outward curving on the other. The flat side faces the bulb. Some projectors use a *double condenser,* which consists of two condensing lenses. The light rays entering the condensing lens are bent inward. The rays then pass through a photographic slide placed upside down between the focusing and projection lenses. The projection lens turns the image right side up and enlarges it.

Some kinds of projectors can be used with both film strips and slides. *Overhead projectors* project pictures

WORLD BOOK illustration by Sarah Woodward

A diagram of slide projection, *above,* shows how a projector beams the image of a slide on a screen. Rays from a powerful light are condensed and sent through the transparent slide. *Condensing* lenses focus the rays to provide a clear image. The slide must be put into the projector upside down because the *projection* lenses invert the image on the screen. A slide projector, *below,* can hold more than 80 transparencies in its circular slide tray.

WORLD BOOK photo

above and behind the operator, who can face the audience and use the projector at the same time. Some projectors can project drawings, maps, pages of books, and other material that is opaque—that is, neither transparent nor on transparent film. These projectors are called *opaque projectors.* Robert A. Sobieszek

Prokaryote, *proh KAR ee oht,* also called *moneran* (pronounced *muh NIHR uhn),* is the name of a group of primitive one-celled organisms. Prokaryotes make up the kingdom Prokaryotae. This kingdom consists of blue-green algae, also called *cyanobacteria,* and bacteria. Prokaryotes live alone or in clusters called *colonies.* The individual organisms can be seen only with a microscope, but some colonies are visible with the unaided eye. Prokaryotae is one of the five kingdoms of living things recognized by most scientists. The other kingdoms are Animalia (animals), Fungi (fungi), Plantae (plants), and Protista (protists). Some scientists classify prokaryotes as part of either the protist or plant kingdom.

Most biologists believe prokaryotes are among the oldest types of organisms. Unlike all other living cells, prokaryotes do not have a nucleus surrounded by a membrane. But they do have a nuclear area that contains DNA, the substance that controls heredity. Prokaryotes also lack typical *organelles,* structures that perform functions in other cells (see **Cell** [Inside a living cell]).

Prokaryotes live throughout the world, even where no other life can survive. For example, blue-green algae live in the water of hot springs as well as in frozen wastelands. Free-living bacteria dwell throughout the soil and water, and parasitic species live within nearly all multi-celled plants and animals. Irwin Richard Isquith

Prokhorov, *PRAW kuh RAWF,* **Alexander Mikhailovich,** *ah lyih KSAN dur myih KY luh vyihch* (1916-2002), was a Russian physicist. In 1953, he and Russian physicist Nikolai Basov stated principles for using the energy of molecules to amplify microwaves. They developed these amplifiers, called *masers,* during the next two years (see **Maser**). For their work, Prokhorov and Basov shared the 1964 Nobel Prize in physics with the American physicist Charles H. Townes.

Prokhorov was born in Atherton, Australia, on July 11, 1916. In 1946, he became a research physicist at the Lebedev Institute of Physics in Moscow. In 1973, he became head of the Institute of General Physics of the Academy of Sciences in Moscow. He died on Jan. 8, 2002. William B. Case

Prokofiev, *praw KAW fyehf,* **Sergei Sergeyevich,** *sehr GAY sehr GEH yuh vihch* (1891-1953), was a major Russian composer. His first symphony, the *Classical* (1918), symphonic fairy tale *Peter and the Wolf* (1936), and cantata *Alexander Nevsky* (1939) are among the most popular classical works. Prokofiev's music has sharp humor, lyric melodies, and percussive use of instruments.

Prokofiev was also a brilliant pianist and often performed his own concertos and solo piano works. His solo piano pieces and nine sonatas became an important part of keyboard music in the first half of the 1900's. Most notable are the *Visions fugitives* (1918) and Piano Sonata No. 7 (1943).

Prokofiev was born on April 23, 1891, in Ukraine. After studying in Russia from 1904 to 1914, he moved to New York City in 1918 and settled in Paris in 1923. Two of his best-known compositions, Piano Concerto No. 3 and the opera *The Love for Three Oranges,* were first performed in Chicago in 1921.

In 1936, Prokofiev settled permanently in Moscow. The major works he composed there include the ballets *Romeo and Juliet* (1938), *Cinderella* (1945), and *The Stone Flower* (1954). Prokofiev composed the first version of his important opera *War and Peace* in 1941 and 1942 and revised it from 1946 to 1952. His Symphony No. 5 (1945) is among the most successful of his seven symphonies. Edward V. Williams

Prologue, *PROH lawg,* is an introduction to a play or other writing. The prologue explains the situation at the start of a play, or it may tell in general terms what the play is about. Sometimes a prologue becomes important and well-known in its own right, as in Geoffrey Chaucer's prologue to his collection of stories, *The Canterbury Tales.* Paul Strohm

Prometheus, *proh MEE thee uhs,* in Greek myths, was a member of the earliest race of gods, called Titans. Prometheus's father was Iapetus, and his mother was either Themis or Clymene.

The god Zeus plotted to destroy humanity by depriving the earth of fire. Prometheus stole fire from the gods and gave it to human beings. Zeus punished him by ordering him bound to a remote peak in the Caucasus Mountains. An eagle came to devour Prometheus's liver every day, and the liver grew back each night. After Prometheus had suffered for many centuries, the hero Hercules killed the eagle and set Prometheus free.

The Greek poet Hesiod described Prometheus as a

Oil painting on canvas (1868) by Gustave Moreau; Musée Gustave Moreau, Paris (Bulloz)

Prometheus was a Greek god who stole fire from the gods and gave it to people. As punishment, he was chained to a rock. Each day, an eagle tore out his liver, which grew back each night.

trickster and a troublemaker. The Greek dramatist Aeschylus presented him as a tragic hero and a champion of humanity in his tragedy *Prometheus Bound.* The German composer Ludwig van Beethoven, the German author Johann Wolfgang von Goethe, and the English poet Percy Bysshe Shelley created works inspired by the Prometheus myth. Justin M. Glenn

Promethium, *pruh MEE thee uhm* (chemical symbol, Pm), is one of the rare-earth metals. Its atomic number is 61, its most stable isotope has a mass number of 145, and its most abundant isotope has a mass number of 147. Its melting point is 1042 °C, and its boiling point is estimated to be about 3000 °C. Three American chemists, J. A. Marinsky, Lawrence E. Glendenin, and Charles D. Coryell, first isolated promethium in 1945. The element exists as radioactive isotopes among the fission products of uranium, thorium, and plutonium. It does not occur naturally. See also **Element, Chemical** (table); **Rare earth.** Larry C. Thompson

Prominence. See **Sun** (Solar activity).

Promontory. See **Cape.**

Pronghorn is a horned and hoofed mammal native to North America. It looks like an antelope, but it is not closely related to antelope or to any other animal with horns or hoofs. The pronghorn is the fastest mammal in the Western Hemisphere. It runs at speeds up to 60 miles (96 kilometers) per hour.

Pronghorns stand 32 to 41 inches (81 to 104 centimeters) high at the shoulder and most weigh 80 to 100 pounds (36 to 45 kilograms). They have large ears, slender legs, and a short tail. Pronghorns vary in color from light tan to reddish-brown, with some white fur on the underparts, rump, face, and throat. Male pronghorns are called *bucks,* and females are called *does.*

Buck pronghorns have black horns with backward curved tips. A hooklike prong sticks out from the front and middle of each horn. The horns grow 10 to 18 inches (25 to 45 centimeters) long. The horns of does are about half that size and usually lack prongs. Many does have no horns at all. Pronghorns are the only animals that shed horns. They shed their horns after the mating season and grow new ones every year. See **Horn.**

Pronghorns are nomadic animals. They roam grasslands from southern Saskatchewan in Canada through the Western United States and into Mexico. In fall and winter, they form large herds, sometimes up to 1,000 individuals. Mating generally occurs from July to October. The young, called *fawns,* are born in spring. A doe will give birth to one, two, or, rarely, three fawns. Fawns reach their mature size at 1 $\frac{1}{2}$ years of age.

Pronghorns eat primarily the leaves of herbs and low shrubs. In winter, they dig through snow for leaves. The chief enemies of pronghorns are coyotes, wolves, and eagles. When a pronghorn senses danger, it bristles the long hairs of its white rump. This action warns other pronghorns of the danger.

Scientists estimate that millions of pronghorns once roamed North America. But by the 1920's, less than 20,000 pronghorns remained. Since then, laws protecting pronghorns have helped increase their population.

Joseph J. Branney, Tom Stack & Assoc.

A male pronghorn, *shown here,* has branchlike horns with hard, black coverings. The animal sheds the coverings each year. Pronghorns roam open grasslands of western North America.

Today, North America has about 600,000 pronghorns.

Scientific classification. The pronghorn is the only member of the family Antilocapridae. It is *Antilocapra americana.*

Valerius Geist

See also **Animal** (picture: Animals of the grasslands).

Pronoun is a part of speech used in place of a noun. Pronouns include such words as *I, you, they, which,* and *that.* Such words provide variety in speaking and writing. The advantage of using pronouns can be seen in the following sentence: *Sally told John that she had met his brother.* Without the pronouns *she* and *his,* this sentence would have to be rephrased *Sally told John that Sally had met John's brother.* The word that a pronoun refers to is called its *antecedent.* In the sentence about Sally and John, the antecedent of *she* is *Sally,* and the antecedent of *he* is *John.*

Pronouns may be classified according to their use into the following types: personal, intensive and reflexive, interrogative, relative, demonstrative, and indefinite. Several pronouns appear in more than one category.

Personal pronouns refer to beings and objects. These pronouns have separate forms that show number, case, person, and gender. *Number* is shown by different forms for singular (*I*) and plural (*we*) pronouns. *Cases* include the subjective case (*he*), objective case (*him*), and possessive case (*his*). *Person* is indicated by separate forms for first person (*I*), second person (*you*), and third person (*she*). *Genders* of a personal pronoun include masculine (*him*), feminine (*her*), and *neuter*—which means neither masculine nor feminine—(*it*).

Personal pronouns must agree with their antecedents in number, person, and gender. However, the case of a pronoun is determined by its use and position in a sentence. In the sentence *Jane liked her teacher,* the pronoun *her* agrees with its antecedent *Jane* in number (singular), person (third), and gender (feminine). But it is in the possessive case, and modifies *teacher.* The table of personal pronouns below lists a complete set of the forms that show number, person, gender, and case.

Where there are two forms of the possessive case listed, the first is used when the noun that the possessive modifies immediately follows: *(That is my book. Where is your book?)* The second is used when there is no noun that immediately follows: *(That is yours. I don't know where mine is.)*

Intensive and reflexive pronouns, such as *myself* and *yourself,* are formed by adding the suffix *-self* or *-selves* to certain forms of the personal pronoun. The suffixes are added to the possessive form of personal pronouns in the first person (*my*) and second person (*your*). The suffixes also combine with the objective form of the third-person pronouns, as in *himself, herself,* and *themselves.* The forms *hisself* and *theirselves* are considered incorrect according to standard grammar.

The intensive pronoun emphasizes the subject of a sentence: *I did it myself.* The reflexive pronoun helps to express an action that reflects upon the subject: *He considered himself lucky to win.* A reflexive pronoun should not be used as a substitute for the subject form of the pronoun. For example, *My husband and I left the house* is correct. *My husband and myself left the house* is incorrect according to standard grammar.

Interrogative pronouns ask questions. The three interrogative pronouns are *who, which,* and *what. Which* and *what* have the same form in all three cases. *Who* has a separate form for each case: *Who came?* (subjective), *Whom did you telephone?* (objective), and *Whose writing is this?* (possessive).

Relative pronouns—*who, which, that,* and *what*—introduce a clause and connect the clause to the word it modifies. The case of a relative pronoun is determined by its function in the clause it introduces:

The boy who is sitting there is my son (subjective).
The boy whom you see is my son (objective).
The boy whose head is turned is my son (possessive).

Many educated speakers accept relative clauses with *who* used in the objective case, except when it is the object of a preceding preposition. Thus:

The boy *who* you see is my son.
The boy *who* you gave the book to is my son.
The boy to *whom* you gave the book is my son.

But not

The boy to *who* you gave the book is my son.

The pronoun *who* refers to people and also sometimes refers to animals and objects, depending on the sense of the sentence. *Which* refers to animals and things. For example, *Alice's essay, which won first prize, was read to the class.* The relative pronoun *that* refers to both beings and things. For example, *Show me the bird that Judy gave you.* The relative pronoun *what* is used in a neuter sense, as in *See what the book says.*

The choice between *that* and *which* may vary with the function of the clause. Clauses introduced by *that* are ordinarily *restrictive*—that is, they provide information essential to the meaning of the sentence. An example is *The car that was totally wrecked was hauled away.* Clauses introduced by *which* are ordinarily *nonrestrictive.* Such clauses add information but are not essential to the meaning of the sentence: *I was able to drive my car, which was only slightly dented.*

Demonstrative pronouns—*this* and *that*—refer emphatically to particular things or actions, as in *This is expensive* or *That is dangerous.* The plural forms of these pronouns are *these* and *those.*

Indefinite pronouns do not indicate a definite gender. Common indefinite pronouns include *all, any, both, each, everybody, few, many, none, one, several,* and *some.* Many of these combine with the suffixes *-one,*

Forms of the personal pronoun

	Singular			Plural		
	Subjective	Possessive	Objective	Subjective	Possessive	Objective
First person	I	my, mine	me	we	our, ours	us
Second person	you	your, yours	you	you	your, yours	you
Third person	he	his	him	they	their, theirs	them
	she	her, hers	her			
	it	its	it			

-body, and *-thing* to form compounds. Some compounds, together with the word *else,* form such pronouns as *someone else* or *everything else.*

Because of changing usage, special difficulty may occur in making verbs agree in number with indefinite pronouns. Problems may also arise in making pronouns agree in number with antecedents that are indefinite pronouns. *Anything, each one, either, neither, nobody, one,* and *something* are singular. For example, *Something is happening outside. Both, few, many,* and *several* are plural. For example, *Many are willing to try.* However, *all, any, each, none,* and *some* may be singular or plural, depending upon the meaning of the sentence. Examples include *All was ready* (singular) and *All were present* (plural). In informal usage, *anybody, anyone, everybody,* and *everyone* are often followed by plural pronouns, even though the verb may be singular. *Everyone was in their place* is informal usage. *Everyone was in his place* is formal.

Growing awareness of the status of women in society has affected usage in this area. According to traditional standards, the proper question, even to an all-woman audience, is: *Would anyone who has lost* his *purse please come to the office?* Many people now use *his* or *her* after indefinite pronouns: (Has anyone lost *his* or *her* pencil?) But not everyone accepts this as proper.

Other usage. Standard usage calls for a subject form of a pronoun after a verb of being: *It was she we elected,* not *It was her we elected.* However, in informal usage, *It's me* and *It's him* can substitute for *It is I* and *It is he.* The selection of the appropriate form often depends on the formality of the occasion.

Expressions that use *than* or *as* often cause confusion about the proper case of the noun. In the sentence *He handles a bicycle better than her,* the objective case of the pronoun *her* may appear to be correct. But it can be seen to be incorrect in terms of standard grammar if the sentence is expanded to read *He handles a bicycle better than she* (*handles a bicycle*). *She* is the subject of the unexpressed verb *handles.* Susan M. Gass

Pronunciation means saying a word aloud. The degree of distinctness of pronunciation is called *enunciation.* Sometimes words may have more than one acceptable pronunciation. Dictionaries list all the acceptable pronunciations.

The variations in pronunciation are called *dialect differences.* Most languages have them. Dialect differences may come from variations in speakers' geographic location, social status, ethnic background, education, age, and occupation. Most people can understand dialect differences within their native language. But people of different backgrounds may have difficulty understanding each other if their pronunciations differ too greatly.

The people of some countries recognize a certain method of pronunciation as the standard spoken form of their language. In some countries, the standard form is the one spoken in its capital. For example, the people of Japan consider the Japanese spoken in Tokyo to be the standard form of their language. In the United States, one standard pronunciation does not exist. People may use many different pronunciations that are considered correct.

A foreign language can seem hard to pronounce because some of its sounds may not be found in a person's native language. For example, the pronunciation of *r* and *th* sounds in English is hard for native speakers of German, French, and Spanish because the sounds are not used in these languages. The German *oe,* the French *u,* and the Spanish *x* have sounds that are not found in English. People must learn how to place their mouth and tongue to make the new sounds of a foreign language.

Pronunciation problems in English. English words follow a number of complicated pronunciation rules. The majority of words follow these rules. However, English has more irregular pronunciations than many other languages have and many occur among the most frequently used words. Largely for this reason, many people consider English a difficult language to pronounce.

Letters and combinations of letters in English often have more than one pronunciation. One reason for this is that there are only 26 letters to represent about 40 different sounds. For example, the *digraph* (two letters representing one sound) *gh* is silent in *dough,* but sounds like *f* in *cough,* a hard *g* in *ghost,* and a *p* in *hiccough.* In Spanish and Italian, the letter *a* is always pronounced using the broad *a* (*ah,* as in *father*). However, the English words *fat, fate, fare,* and *far* each have a different *a* sound. People must memorize pronunciations that do not follow set rules.

Another reason rules do not apply simply and regularly to the pronunciation of English is that the language has borrowed so much from other languages. Many borrowed words follow the pronunciation rules of the language from which they came rather than the rules for native English words. For example, in most cases an *e* added to the end of a word in English is silent. Its only purpose is to make the vowel before it long. Thus, in *cape* (pronounced *kayp*) the *e* is silent, while the *a* is long. But in the word *cafe* the *e* is pronounced *ay,* while the *a* is short and almost slurred over. *Cafe* is one of the words that we have taken from the French. The final *e* of the French word *café* has an acute accent over it, which gives it the sound of a long *a.* In English, we usually drop the accent marks of other languages but keep much the same pronunciation.

English also has irregular pronunciations because over a period of years the sounds of many words have changed but the spellings have remained the same. In the 1300's, for example, the words *sane* and *sanity* were both pronounced with a short *a* (as in *hat*). The sound of the *a* in *sane* soon changed to a long *a,* but the original spelling had already been established as the standard in printed materials. In another case, the original pronunciation of the digraph *oo* in all words was a long *o* (*oh*). During the 1700's, the pronunciation of *oo* changed. Some of the variations included the *oo* of *food,* the short *u* of *wood,* and the *uh* of *flood.*

English dialects in the United States. There are three major regional dialects in the United States: (1) Northern, also called Eastern or New England; (2) Southern; and (3) Midland, also known as Western or Midwestern. Many local dialects exist within the major ones.

The Northern dialect occurs mainly in New York and New England. Some characteristics of Northern pronunciation include using the broad *a* in words that could use a short *a* (*LAH vuh* for *LA vuh* in the word *lava*), dropping the *r* sound (*cah* for *car*), and using the short *o*

instead of the open *o* (*fahg* for *fawg* in the word *fog*).

The Southern dialect occurs mainly in the Southern States. Some of the features of this dialect include the loss of the *r* sound (*SUH thuhn* for *SUHTH uhrn* in the word *southern*), the use of the broad *a* for a long *i* (*tahm* for *tym* in the word *time*), and the use of a short *i* for an *e* before a nasal sound (*pihn* for *pen*).

The Midland dialect is spoken in Pennsylvania, West Virginia, and most states west of the Appalachian Mountains. This dialect is sometimes considered the standard form of American English because it is spoken over the largest geographic region. Pronunciation characteristics of the Midland dialect include the use of the *r* sound in all word positions, the use of the open *o* for a short *o* (*fawg* for *fahg* in the word *fog*), the use of a long *i* (*tym* in the word *time*).

Since the early 1900's, pronunciation in the United States has become more standardized because people throughout the country have become more and more exposed to each other's speech patterns. This exposure occurs through such means as movies, radio, television, and travel.

Learning pronunciation must start with learning about syllables. Syllables are the natural divisions of a word according to pronunciation. A new syllable is formed around each new vowel sound. Each syllable stands by itself in pronunciation.

Where two vowels are separated by a consonant, the consonant is usually pronounced with the second vowel. Genus is broken up as *ge-nus,* the *n* belonging to the second syllable. The consonant is pronounced with the first vowel when that vowel is short but stressed. Thus, *general* becomes *gen-er-al.*

Two consonants that come together in a word are pronounced separately and belong in separate syllables. Garden is broken up as *gar-den.* Among the consonants which cannot be separated are *ph, th, sh, ch,* and others that are pronounced as a single sound.

Most difficult-to-pronounce article titles in *The World Book Encyclopedia* are followed by their pronunciations. In the pronunciations, the words are divided into syllables and respelled according to the way in which each syllable sounds. Accents are indicated by syllables set in capital letters (main or primary accent) and small capitals (secondary accent). See also *Key to pronunciation* in the front of the "A" volume.

Any long word can be broken up into parts that are already familiar. The word *incantation* is long and looks hard. But it can be broken up into familiar parts—*in-can-ta-tion.* The first part is the same as the first syllable of *invade.* The second part is the same as a tin *can.* The third and fourth parts look like *nation,* beginning with *t* instead of *n.* Thus, *incantation* is pronounced *IHN kan TAY shuhn.* Many persons already know the word *plantation* and find it easy to substitute *inc* for *pl* in learning to say *incantation.*

Proofreading means reading printed copy and marking any errors found in it. When a body of type is set, the typesetter prints a *proof* (trial copy) from it. The proofreader then compares the proof with the original manuscript, marking any errors with a set of symbols called *proofreaders' marks.* The proofreader makes one mark in the copy to identify the location of the correction. A corresponding mark is made in the margin to specify the kind of correction needed. The proofreader reads carefully, looking for any misspellings, mistakes, or broken type. The proofreader also reads with an awareness of content, questioning anything inconsistent. When working with publications typeset on desktop computers, the proofreader must also check for correct alignment and positioning of borders and pictures.

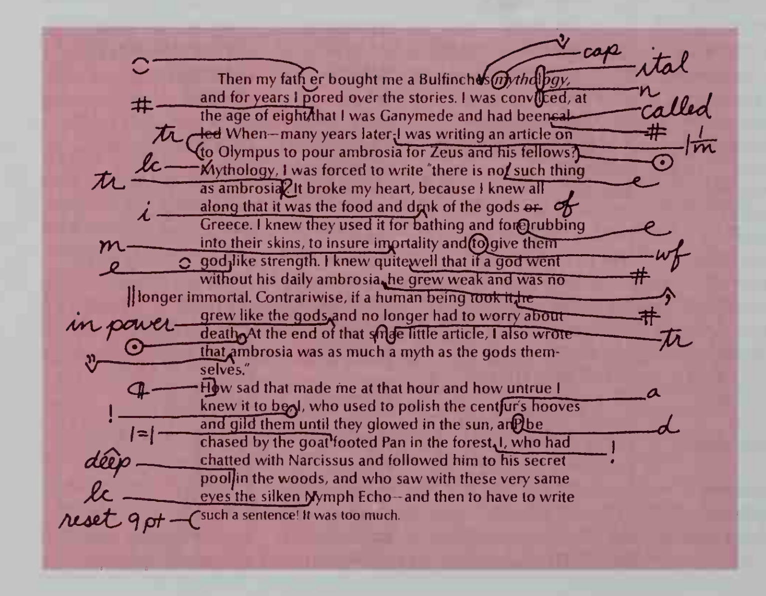
After the proof is read, the typesetter makes the corrections and any other changes called for by the author, editor, or client. When no more corrections need to be made, the type is ready for printing.

Proofreaders' marks are shown in the table with this article. Some of the most common include:

The *delete* sign (ℓ) indicates words or letters should be eliminated. The Latin word *stet,* which means *let it stand,* is used to restore words or letters crossed out.

Italic letters (ital) are slanting letters generally used for titles of publications and for stressed words. *Roman* letters (rom) are straight up-and-down. **Boldface** type (bf) is heavier than ordinary type. It is often used for headings.

Lower case (lc) means small letters. Old handset type was kept in sectioned boxes called *cases.* Small letters were kept in the case below capital letters. Almost all type is set by computer today, but capitals and small letters are still called upper case and lower case.



Wrong font (wf) means that the wrong kind of type has been used. A complete set of one design of type is called a *font.*

Accidental errors that occur in typesetting are called *typographical errors* or *typos. Author's alterations,* or *aa's,* are changes, other than corrections, that the author or client has requested.

William C. Esler

Then my fath er bought me a Bulfinchs mythology,
and for years I pored over the stories. I was convited, at
the age of eight that I was Ganymede and had been cal-
led When—many years later I was writing an article on
to Olympus to pour ambrosia for Zeus and his fellows
Mythology, I was forced to write "there is no such thing
as ambrosia It broke my heart, because I knew all
along that it was the food and drnk of the gods or
Greece. I knew they used it for bathing and for rubbing
into their skins, to insure imortality and to give them
god like strength. I knew quitewell that if a god went
without his daily ambrosia he grew weak and was no
longer immortal. Contrariwise, if a human being took it he
grew like the gods and no longer had to worry about
death At the end of that smae little article, I also wrote
that ambrosia was as much a myth as the gods them-
selves."
How sad that made me at that hour and how untrue I
knew it to be I, who used to polish the centurs hooves
and gild them until they glowed in the sun, and be
chased by the goat footed Pan in the forest I, who had
chatted with Narcissus and followed him to his secret
pool in the woods, and who saw with these very same
eyes the silken Nymph Echo—and then to have to write
such a sentence! It was too much.

Then my father bought me a Bulfinch's *Mythology,* and for years I pored over the stories. I was convinced, at the age of eight, that I was Ganymede and had been called to Olympus to pour ambrosia for Zeus and his fellows. When—many years later—I was writing an article on mythology, I was forced to write "there is no such thing as ambrosia." It broke my heart, because I knew all along that it was the food and drink of the gods of Greece. I knew they used it for bathing and for rubbing into their skins, to insure immortality and to give them godlike strength. I knew quite well that if a god went without his daily ambrosia, he grew weak and was no longer immortal. Contrariwise, if a human being took it, he grew like the gods in power and no longer had to worry about death. At the end of that same little article, I also wrote that "ambrosia was as much a myth as the gods themselves."

How sad that made me at that hour and how untrue I knew it to be! I, who used to polish the centaur's hooves and gild them until they glowed in the sun, and be chased by the goat-footed Pan in the forest! I, who had chatted with Narcissus and followed him to his secret pool deep in the woods, and who saw with these very same eyes the silken nymph Echo—and then to have to write such a sentence! It was too much.

Proofreaders' marks on the printed proof show corrections that must be made in typeset matter, *left.* The corrected version, or revised proof, is shown above.

National Archives, Collection U.S. Office of War Information

Two propaganda versions of Adolf Hitler show the German dictator from opposite viewpoints. A pro-Hitler poster, *left,* portrays him as a heroic warrior crowned with a halo of light. An anti-Hitler cartoon, *right,* pictures him as a ridiculous, loudmouthed tyrant.

Propaganda is one-sided communication designed to influence people's thinking and actions. A television commercial or a poster urging people to vote for a political candidate might be propaganda, depending on its method of persuasion.

Propaganda differs from education in democratic societies. But education in a dictatorship can involve teaching children and youth by techniques that could be classified as propaganda. Educators in democratic societies teach people how to think, but propagandists tell them what to think. Most educators are willing to change their opinions on the basis of new evidence, but propagandists ignore evidence that contradicts them. Educators present all sides of an issue and encourage debate. Propagandists build the strongest possible case for their views and discourage discussion.

The intention of the communicator to influence or deceive is an important issue in identifying propaganda. However, experts disagree about what is propaganda and what is not, and whether propaganda differs from other forms of persuasion, such as advertising and political campaigning. Some look upon all slanted communication as propaganda. Others believe that the method of persuasion determines whether a message is propaganda. For example, the majority of advertisers and political campaigners function openly and state their purposes truthfully. Other advertisers and political campaigners present any combination of truths, half-truths, lies, and distortions that they think will most effectively influence their audience. Some experts say all these people are propagandists. Others regard only the second group as propagandists.

Some people consider propaganda neither good nor bad. For example, many favor the use of propaganda to raise money for charity. Other individuals argue that the public needs reliable information to make wise decisions, and that propaganda blocks the spreading of such information. They also fear that propaganda deadens people's power of reasoning. The results of some propaganda may be short term and relatively insignificant, such as the purchase of a product. Other types of propaganda can have more serious results.

The greatest use of propaganda occurs during wartime. At such times, government propaganda campaigns urge people to save resources, volunteer for military service, support the war effort, and make sacrifices necessary for victory. *Psychological warfare* is a type of propaganda that aims to weaken the enemy's will to fight or belief in their government. A related technique, called *brainwashing,* is used against prisoners. It combines political propaganda with harsh treatment to reduce a prisoner's resistance.

Much wartime propaganda is called *covert* (secret) *propaganda* because it comes from hidden sources. For example, a propagandist might try to discourage enemy troops by sending them counterfeit newspapers reporting huge losses among their forces. Some covert propaganda is spread by people in a country who secretly support its enemies. A group of such people is called a *fifth column.* The opposite of covert propaganda is called *overt* (open) *propaganda,* which comes from known sources.

How propaganda works

Propaganda appeals to its audience in three ways. (1) It calls for an action or opinion that it makes seem wise and reasonable. (2) It suggests that the action or opinion is moral and right. (3) It provides a pleasant feeling, such as a sense of importance or of belonging.

Many propaganda methods are common-sense techniques that resemble those of persuasive speaking. These techniques include gaining people's trust, simplicity and repetition, and the use of symbols. However, propagandists often use such underhanded methods as distortion, concealment, and lying. In nations ruled by dictators, governments increase the effectiveness of their propaganda by using censorship.

Gaining people's trust. Above all, propagandists must be believable, and their audience must consider them reliable authorities. One way to gain an audience's trust is to report unfavorable news that the audience knows or will discover. During World War II (1939-1945), the British Broadcasting Corporation (BBC) made propaganda broadcasts to Europe. The BBC began many

newscasts with a report of British defeats and losses. This practice helped give the BBC a worldwide reputation for truthfulness.

Another way to gain people's trust is to agree with their existing opinions. Scientists have found that people place most trust in speakers and writers whose ideas are similar to their own. As a result, propaganda is most successful if much of it agrees with what people already believe and if only a little of it is new.

Simplicity and repetition. Propaganda must be easy to understand and to remember. As far as possible, propagandists make their appeals in simple, catchy slogans that they repeat over and over. The Nazi dictator Adolf Hitler wrote: "The intelligence of the masses is small. Their forgetfulness is great. They must be told the same thing a thousand times."

The use of symbols involves words and illustrations that bring strong responses from people. Individuals react not only to the actual meaning of words and the actual content of pictures but also to the feelings aroused by such symbols. For example, nearly all cultures have favorable reactions to a picture of a mother and baby or to such words as *homeland* and *justice*. Propagandists try to create an association in people's minds between such symbols and the messages they are trying to spread. Powerful negative images are frequently used to increase prejudice, hostility, and hatred toward the desired targets of propaganda.

American Cancer Society

Propaganda uses emotions rather than logic to persuade its audience. This antismoking poster tries to create an association in people's minds between smoking and unattractiveness.

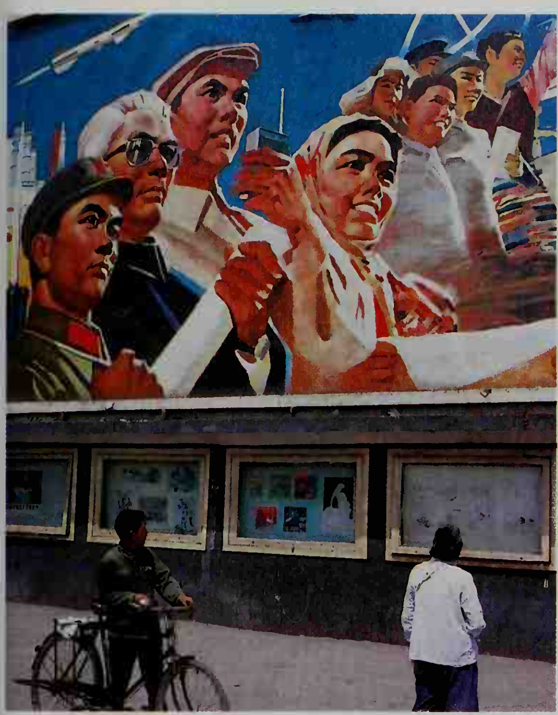
Distortion and concealment. Propagandists deliberately exaggerate the importance of some facts and twist the meaning of others. They try to conceal facts that might prevent the response they seek from people. They also try to shift attention away from embarrassing facts that cannot be hidden.

Lying. Deliberate lying is relatively rare as a propaganda technique because propagandists fear their lies might be discovered and they might lose their audience's trust. Propaganda usually includes some accurate information. But some propagandists readily lie if they think they can deceive their audience. Propagandists may believe in their causes, but their chief goal is to shape and control the public's beliefs and actions.

Censorship is most common where the government controls the newspapers, television, and other means of communication. It increases the effectiveness of propaganda because the government can silence people who contradict its official views. See **Censorship**.

Who uses propaganda?

Propaganda comes from many sources. Three of the most important ones are (1) governments, (2) organizations, and (3) businesses.



Governments. Nearly all governments, including democratic ones, use propaganda to win support from other nations. Governments also sponsor propaganda and information programs to promote desired behavior among their own citizens. For example, government propaganda might urge people to support certain policies or to oppose foreign political systems.

Organizations represent members of various professions, religions, and many other fields. During election campaigns, many organizations distribute propaganda that supports candidates who agree with their views. Between elections, organizations may also use propaganda to influence public opinion. Many groups employ people called *lobbyists,* who work to persuade legislators to support their programs. A group that tries to further its own interests by exerting pressure on legislators or other officials is often called a *pressure group.* Group members outline their goals on such controversial topics as abortion, busing, civil rights, the environment, foreign policy issues, gun control, and nuclear energy.

Businesses often use propaganda in their advertising. For example, a mouthwash commercial on television might be aimed at people's desire to be attractive and popular. Advertising agencies employ psychologists and other social scientists to study why people buy certain products. They try to determine what slogans will lead to purchases. Many large businesses also have public relations departments that use propaganda to spread favorable opinions of company policies.

History

Today, the word *propaganda* suggests shady or underhanded activity, but that was not its original meaning. The term came from the Latin name of a group of Roman Catholic cardinals, the *Congregatio de Propaganda Fide* (Congregation for the Propagation of the Faith). Pope Gregory XV established the committee—called the *propaganda* for short—in 1622 to supervise missionaries. Gradually, the word came to mean any ef-

© Dennis E. Cox, Click/Chicago

Governments use propaganda to promote desired behavior among their citizens. This Chinese poster encourages people to adopt modern attitudes in industry and in education.

fort to spread a belief. It acquired its present meaning after World War I (1914-1918), when writers exposed the dishonest but effective techniques that propagandists had used during the war.

Propaganda as it is used today began in the early 1900's. V. I. Lenin, who led the revolution that established Communist control of Russia, emphasized the importance of propaganda. He distinguished between two types of persuasion—propaganda and agitation. Lenin regarded propaganda as the use of historical and scientific arguments to convince the well-educated minority. He defined agitation as the use of half-truths and slogans to arouse the masses, whom he considered incapable of understanding complicated ideas. Traditionally, each Communist Party has included a unit that specializes in *agitprop*—agitation and propaganda.

During World War I, the Allies—including Britain, France, Russia, and the United States—fought the Central Powers, led by Germany. The warring nations conducted widespread propaganda operations. The major U.S. propaganda effort was handled by an agency called the Committee on Public Information. The committee distributed more than 100 million posters and publications designed to increase support for the war.

Between the wars, several famous dictators used propaganda to help them achieve power. In 1922, Benito Mussolini established a Fascist dictatorship in Italy. Fascist propaganda promised to restore Italy to the glory of ancient Rome. Joseph Stalin, who became dictator of the Soviet Union by the late 1920's, used propaganda and terrorism to crush all opposition. The Soviet Union had been formed under Russia's leadership in 1922. In 1933, Adolf Hitler set up his Nazi dictatorship in Germany. The Nazis' effective use of education, motion pictures, press, and radio to shape opinion and behavior remains one of the most famous examples of propaganda.

During World War II, Germany, Italy, and Japan fought Britain, the Soviet Union, the United States, and the other Allies. All of the major powers spread far-reaching propaganda. The United States had two primary propaganda agencies. The Office of War Information handled overt propaganda, and the Office of Strategic Services (OSS) carried on covert operations.

After World War II ended in 1945, the Cold War began. The Communist nations, led by the Soviet Union, and the non-Communist nations, led by the United States, used a variety of propaganda techniques to influence world opinion, as well as their own citizens.

In 1953, the U.S. government created the U.S. Information Agency (USIA) to create support of its foreign policy. The Voice of America, the radio division of the USIA, broadcast entertainment, news, and propaganda throughout the world. The government used the Central Intelligence Agency (CIA) to spread covert propaganda against governments unfriendly to the United States. These governments included those of the Soviet Union and the Communist countries of Eastern Europe. The CIA also provided funds to establish radio networks called Radio Free Europe and Radio Liberty, which broadcast to Communist countries.

Since 1960. In the early 1960's, China began to challenge the Soviet Union for leadership of the Communist world, and a bitter propaganda struggle developed between them. Each accused the other of betraying Communism. After 1970, several Communist and non-Communist nations at times enjoyed friendlier relations and altered their propaganda operations against one another. The United States and the Soviet Union enjoyed such relations in the early 1970's and beginning again in the late 1980's. In 1989 and the early 1990's, Communists lost control of the governments of many Eastern European countries and the Soviet Union, and in 1991 the Soviet Union broke up into a number of independent states. However, Radio Free Europe continued to broadcast to Eastern Europe, and Radio Liberty kept transmitting to former Soviet areas. In addition, Voice of America continued to broadcast throughout the world. Radio Free Asia, another U.S. service, began broadcasting in 1996. Its programs are transmitted to China, North Korea, and Southeast Asia. Propaganda is still used today in many nations. Taylor Stults

Different kinds of propellers produce the thrust that moves ships through the water and airplanes through the air. A typical ship propeller, *above left,* has three or more broad blades. Most airplane propellers have two or more narrow blades.

Propane. See **Butane and propane.**

Propeller is a device for producing motion that has blades mounted on a power-driven shaft. A propeller changes an engine's power into forward thrust. The best-known types of propellers are those that drive ships and airplanes. A propeller's rotating blades produce a kind of force known as *aerodynamic lift* that pushes or pulls an aircraft through the air and a ship through the water (see **Aerodynamics** [Lift]). Airplane propellers and marine propellers work in much the same way, but they produce motion in different fluids.

The first screw propeller was developed by John Fitch in 1796. His propeller was in the form of a spiral around a cylindrical rod. John Ericsson, a Swedish-American inventor, developed the first successful propeller with blades in 1836 (see **Ericsson, John**).

Airplane propellers are also known as *airscrews.* They have two or more blades. The cross sections of the blade are airfoil sections similar to those used in airplane wings. The *pitch* is the angle between the cross section of the blade and the plane through which the propeller rotates. Propeller blades are twisted, and so the pitch changes along the length of the blade. As a result, the propeller blade meets the air at the angle that gives it the greatest efficiency. The efficiency of a propeller drops off and the noise it makes increases rapidly as the speed of the tips of its blades increases beyond the speed of sound.

A fixed-pitch propeller is one in which the angle at which the blades are set is fixed. Such propellers are efficient only at one speed of flight and for a definite power output. They usually are used on small aircraft.

A constant-speed propeller has variable pitch. The angle of the blades adjusts continuously to provide the most efficient operation at every flight speed. The propeller automatically turns the same number of revolutions per minute under all conditions of flight. It does not gain speed in dives or lose speed in climbs. This propeller is used on transport aircraft.

Many constant-speed propellers have special features that are used in emergency situations. For example, a *feathering* device enables the pilot to increase the blade angle enough to streamline the blades with the engine stopped. In case of an engine failure, the pilot can *feather,* or rotate, the blades so that their leading and trailing edges parallel the path of flight. This action decreases the propeller's air resistance and prevents possible damage to the engine.

Another feature of many constant-speed propellers is *reversible-pitch.* On such propellers, the blades can be set at a negative pitch so that the direction of the thrust is reversed. This acts as a brake and reduces the landing run on the ground. Reversible-pitch is of great value for large airplanes, particularly when runways are covered with ice or snow, making the wheel brakes ineffective.

Marine propellers range in diameter from 10 inches (25 centimeters) for small boats to more than 25 feet (7.5 meters) for large tankers. They are usually made of manganese and bronze.

Battleships and large tankers may have propellers with five or six blades, while smaller ships use three- or four-bladed propellers. Propellers on single-screw ships turn to the right, or clockwise, when viewed from the stern when the ship is going ahead. Twin-screw vessels usually have out-turning propellers. The starboard screw turns clockwise, and the port screw, counterclockwise, for ahead motion. Twin-screw ships are easily steered by reversing one of the engines while the other goes full ahead. Destroyers and other small craft can make sharp turns in this way. Conventional propellers are less effective at high speeds because of *cavitation,* the formation of a vacuum as the propeller turns. A propeller called a *supercavitating* propeller is designed so that cavitation increases the effectiveness of the propeller at high speeds. Allen Plotkin

Property, in law, means the rights people have in things. Such rights are often called *ownership.* Property may refer to a car, a farm, a watch, or anything else that

is owned. Property also may refer to interests in things that are owned by more than one person. Such interests include stock in a corporation. The corporation owns the machinery, the raw materials, and the finished products. But the stockholder is entitled to share in its profits as an owner of the corporation. Property may be classified in two ways. *Real property* includes interests in land and the things permanently attached to it, such as buildings and trees. All other things are *personal property.*

Various types of interests in property exist in American and English law. For example, an owner of land has an *absolute* property interest if the owner is the only person with an interest in the land. The owner may allow another person to occupy it as a farm for 10 years. During that time, the owner is entitled to be paid for the use of the land but cannot use it. In this case, the owner has a *qualified nonpossessory* property interest—that is, a right to regain full ownership and possession of the land in the future. The farmer is entitled to possess the land and can prevent anyone from interfering with the use of the property. The farmer has a *qualified possessory* interest. During the 10 years, the farmer can provide for an *easement* (limited right of use) by permitting a neighbor to cross the land to reach a road or other piece of land. The easement gives the neighbor a *qualified nonpossessory* interest.

Property interests may be acquired in several ways. People may buy property, find it, or receive it as a gift. They also may get property by a court order, as in the distribution of the estate of a person who has died without leaving a will. Joel C. Dobris

Property tax is a tax collected from the owners of buildings, land, and other taxable property, including business equipment and inventory. Some governments also collect taxes from the owners of such property as stocks and bonds.

Property taxes provide much of the income of cities, counties, towns, and school districts in the United States, Canada, and many other countries. Local governments depend on these taxes to help finance education, police and fire protection, street repair, and other services. Some state and provincial governments also collect property taxes.

The government of a community sets an annual tax rate to determine each property owner's tax bill. This rate is a percentage of the *assessed* (estimated) value of the property. In many cases, the assessed worth is less than the property's market value. For example, a house might have a market value of $100,000 but be assessed at only $60,000. If the tax rate were 5 percent, the annual property tax would be $3,000. See **Assessment.**

The major problem with property taxation is that much property is not assessed fairly and uniformly. Another drawback is that assessments and rates change too slowly to keep up with rising prices. In countries with high rates of inflation, assessments have often fallen far behind market values. Some people oppose property taxes because they believe property ownership is a poor measurement of ability to pay. But others argue that property owners are the people who benefit most from community services, and so they should pay more for these services. In 1978, California voters approved a measure, called Proposition 13, that reduced state property taxes. Several other states soon enacted similar laws. Vito Tanzi

Prophet, in religion, is the title given to a person who claims to communicate God's will to others. The life and teachings of prophets have provided the basis for some religions. For example, Islam is based on the life and teachings of the Prophet Muhammad. Similarly, Joseph Smith, the founder of the Mormon Church, is considered a prophet by his followers. The most famous prophets lived in ancient Israel during Biblical times.

There were two types of prophets in ancient Israel—*professional prophets* and *classical prophets.* Professional prophets earned a living by trying to determine for their clients the nature of God's will in regard to specific issues and problems. Classical prophets did not choose to become prophets. They believed God called them to proclaim His message to the people of Israel. The classical prophets are also called *literary prophets* because their words are recorded in Biblical books. The magnificent poetry of many of their sayings represents a high point in Hebrew literature.

Classical prophets introduced the idea that God ruled over all nations, not just Israel. These prophets spoke directly to the major leaders of their time. They urged the people to remain faithful to God and to act justly with each other. Carol L. Meyers

See also **Bible** (Books of the Hebrew Bible) and the list of *Related articles* at the end of the **Bible** article.

Prophylaxis, *PROH fuh LAK sihs,* means any treatment that protects a person from a disease. Prophylaxis is also called *preventive* treatment. Treatment is called *corrective* or *curative* when the patient already has a disease or unhealthful condition.

Preventive measures have been very important in improving health and prolonging life. Methods pioneered by Edward Jenner, Robert Koch, Louis Pasteur, and others proved it is possible to strengthen the body so it will be immune to certain diseases through the use of vaccines. *Collective prophylaxis* is preventive medicine in the field of public health. For example, sanitation and widespread immunization help protect communities from many diseases. Alan R. Hinman

See also **Disease** (Preventing disease); **Immunization.**

Proportion is a relationship of equivalence between two ratios. For example, the equation $\frac{a}{b} = \frac{c}{d}$ is a proportion. The equation states that a is related to b in the same way that c is related to d. It can also be written as $a{:}b = c{:}d$. Equivalent ratios are said to be *in proportion.*

In the proportion $\frac{a}{b} = \frac{c}{d}$, a is called the first term; b, the second term; c, the third term; and d, the fourth term. The first and fourth terms are called the *extremes* of the proportion, and the second and third terms, the *means.* For all proportions, the product of the means equals the product of the extremes. For the proportion

$\frac{a}{b} = \frac{c}{d}$, it is therefore true that $a \times d = b \times c$. This property of proportions provides a formal way of finding an unknown term of a proportion when the three remaining terms are known. For example, the unknown term n in the proportion $\frac{9}{3} = \frac{15}{n}$ can be determined by solving the equation $9 \times n = 3 \times 15$:

$$9n = 3 \times 15$$
$$9n = 45$$
$$n = 5$$

When two ratios are in proportion, the terms of one ratio can be multiplied by a certain number to produce the terms of the other ratio. In the proportion $\frac{2}{4} = \frac{4}{8}$, for example, both terms of the ratio $\frac{2}{4}$ can be multiplied by 2 to produce $\frac{4}{8}$.

All ratios considered as numbers that are in proportion to one another equal the same number. This number is called a *constant of proportionality.* For example, the ratio of the circumference *(c)* to the diameter *(d)* of any circle is in proportion to the same ratio for any other circle. All such ratios ($\frac{c}{d}$) are equal to 3.14159. This constant of proportionality is known as *pi* (π).

The idea of proportion is the basis for many laws of astronomy, biology, chemistry, and physics. Many of these laws contain famous constants of proportionality. The idea of proportion is also used in the social sciences and the arts. Architects use it in designing scale models and drawing building plans. Thomas E. Kieren

Proportional representation is a system of electing members of a legislature. It is designed to give a political party a share of the seats in the legislature in proportion to its share of the total vote cast in an election. It also offers opportunities for candidates of minority parties to be elected. Proportional representation has three basic features: (1) three or more legislators are chosen from each district at the same time; (2) the ballots are counted in a special way to give each political party its share of the vote; and (3) there are usually more than two active parties. These elements are present in both the *List System* and the *Hare System.*

The List System. Each political party offers a list of candidates for the legislature, and voters mark their ballot for the party they choose, not the individual candidates. If a party wins 40 percent of the vote, it receives 40 percent of the available seats in the legislature. In a campaign to fill 100 seats, the first 40 candidates on the party's list would be elected. If another party wins 20 percent of the vote, its top 20 candidates receive seats in the legislature. The Netherlands, Belgium, and Israel are among the countries using this system.

The Hare System, or single transferable vote, is much more complicated. Voters number the candidates on their ballot in the order of their choice. After counting the total number of ballots, election officials determine a mathematical *election quota,* the minimum needed for election. Then they count all the first choices. A candidate who wins the quota of first choices is declared elected. All of this candidate's ballots above the quota are redistributed to the candidates chosen second by the voters. Next, the candidate with the fewest number of ballots is eliminated. This person's ballots are redistributed to the second-choice candidates listed. If the second-choice candidate has already been elected, the ballot is passed on to the third choice, and so on. This process continues until enough candidates have reached the election quota to fill all the seats. An English lawyer, Thomas Hare, described the system in 1859. The Republic of Ireland has used it since 1920.

Robert Agranoff

Propulsion, Jet. See Jet propulsion.

Prose is the language of everyday speech and writing. It is also one of the two major forms of literary expression. The other is poetry. Letters and newspaper and magazine articles are written in prose. So are biographies, essays, histories, novels, and a majority of plays. Most prose, unlike much poetry, has no regular meter. Prose also lacks rhyme, which is a feature of many poems. However, prose writers often use such poetic devices as alliteration and repetition, and some writers compose highly rhythmical prose. In many cases, it is difficult for a reader to clearly distinguish between prose and poetry.

Prose styles range from simple to complex. For hundreds of years, writers and literary critics have argued about the ideal prose style. For example, Francis Bacon, an English author of the early 1600's, favored a simple, clear, straightforward style of writing. He composed short sentences with few adjectives. On the other hand, Sir Thomas Browne, an English author of the mid-1600's, preferred to use a richer, more elegant prose style. He wrote graceful, rhythmic sentences that sounded poetic.

The King James Version of the Bible, published in 1611, combined certain features of both styles of prose. Its elegant yet natural style greatly impressed many readers. Since its publication, the King James Version has been the single most important influence on English prose writing.

During the 1900's, many writers of English prose favored a brisk, clear style and tried to copy the rhythm and vocabulary of ordinary speech. This conversational style is exemplified by the works of Ernest Hemingway, Gertrude Stein, William Carlos Williams, and Virginia Woolf. William H. Epstein

Proserpina. See Persephone.

Proslavery movement was an attempt by Southerners to justify and expand slavery in America between the 1830's and 1860. Southerners argued that both the Bible and history endorsed slavery, that *emancipation* (freeing the slaves) was impractical, and that slavery was necessary to save the Southern economy. John C. Calhoun and other well-known Americans defended slavery. They called it "the law of nature," "a positive good," and "the greatest and most admirable agent of civilization."

The proslavery movement wanted to extend slavery into the Western territories and wanted to add Texas to the Union. Former President John Quincy Adams called the Mexican War (1846-1848) "a slave-power conspiracy," a means to gain more slave territory. Abolitionists condemned efforts to acquire Cuba as an attempt to add another slave state. In the late 1850's, some Southerners wanted the foreign slave trade reopened. The Civil War destroyed slavery in the nation and ended the proslavery movement. James M. McPherson

See also **Civil War** (The conflict over slavery); **Slavery** (Slavery in the United States).

Prospecting is the process of searching for valuable deposits of minerals or fuels. Early prospectors in the United States were lured by the promise of gold, oil, and other valuable minerals. Gold prospectors explored canyons and mountains with picks, shovels, gold-pans, and other simple equipment. Petroleum prospectors drilled shallow holes looking for oil reservoirs. Most early prospectors had no scientific training. Modern prospectors, sometimes called *explorationists,* are scientists with training in geology, geophysics, and mining.

Prospectors today mainly search for deeply buried deposits, because most minerals that were near the surface have already been discovered. They usually begin by examining areas of known deposits to determine the conditions under which valuable minerals or fuels occur. Using satellite photographs of Earth's surface, prospectors choose a site whose surface conditions indicate the likely presence of minerals underground.

To learn what lies underground, prospectors have the site's topsoil, water, and plants analyzed for *trace elements.* Trace elements are tiny amounts of certain chemical elements. Their presence may indicate deposits of a certain mineral below the surface.

Prospectors use several instruments in their search for deposits. Gravimeters, or gravity meters, measure the pull of gravity at the earth's surface. Metals and other dense rocks increase gravitational pull while light, porous minerals decrease it. Magnetometers record changes in the earth's magnetic field. Magnetometers help prospectors find petroleum, certain iron ores, and other minerals with magnetic properties. Prospectors use lamps that give off ultraviolet light to find fluorescent minerals. When illuminated with this light, these minerals glow with definite colors. Geiger counters and scintillation counters measure radiation. Prospectors use them to find radioactive minerals such as uranium and thorium. Seismographs measure movements of rock, such as shaking produced by earthquakes or vibrations created by underground sound waves. In the *seismic method* of exploration, prospectors use explosives to create sound waves. By studying the speed and direction of waves reflected by buried rock layers, prospectors can determine the structure of the layers.

Once prospectors have determined that a site contains valuable minerals, they drill deep holes at the site to obtain rock cores or fragments. These samples help the prospectors determine the size, value, and exact location of the deposit. William Hustrulid

Prosser, Gabriel. See Gabriel.

Prostaglandin, *PRAHS tuh GLAN duhn,* is the name of a group of important chemical compounds. They are modified versions of fatty acids found throughout the bodies of human beings and all other animals. They help control stomach acid production, regulate blood pressure and body temperature, and alter muscles of the bronchi, intestines, uterus, and other body organs. Prostaglandins also play a major role in reproduction.

Scientists believe prostaglandins serve as part of the body's control system. Hormones, another important group of chemical substances, carry messages from the glands to various organs in the body (see Hormone). Prostaglandins, on the other hand, act locally between cells. They have a role in protecting the body from certain unhealthful conditions. For example, prostaglandins made in the stomach prevent ulcers. However, when a person's physical condition is impaired, prostaglandins can make things worse if produced in large amounts. This sometimes occurs when a person is in shock.

Prostaglandins were first discovered in the early 1930's. But until the late 1960's, scientists did not learn how to produce them from common materials. Since then, researchers have found how to make prostaglandin *analogues* (stable, long-acting versions of prostaglandins) and *antagonists* (chemicals that block the action of prostaglandins). They also have found that aspirin works by preventing the formation of prostaglandins from certain fatty acids.

Since the early 1970's, prostaglandin drugs have been used to perform abortions or to bring on childbirth. In addition, experiments show that prostaglandins—and their analogues and antagonists—might be used to treat many kinds of disorders. Such disorders include arthritis, asthma, blocked nasal passages, high blood pressure, and ulcers. Kermit L. Carraway

Prostate cancer, *PRAHS tayt,* is an uncontrolled division of cells in the prostate gland, a walnut-sized internal organ of the male reproductive system. In the United States, prostate cancer kills more men than any other cancer except lung cancer. African American men have the highest rate of prostate cancer in the world. Individuals have an increased risk of prostate cancer if other men in their families have also had the disease.

A cancerous prostate gland may become enlarged and press on the *urethra,* the tube through which urine leaves the body. The expanding gland may also put pressure on the bladder. Many prostate cancer patients consult a doctor because this pressure causes frequent urination or difficulty passing urine.

Doctors must test to determine if these symptoms are due to cancer or to noncancerous enlargement of the prostate, another common condition. The first such test is often a digital rectal examination, in which a doctor feels the prostate gland directly by inserting a finger, covered with a lubricated glove, into the patient's rectum. A lump or an area of hardness may indicate cancer. Another means of diagnosing prostate cancer is a blood test that measures a protein called *prostate-specific antigen* (PSA). Elevated levels of PSA, which is produced only in the prostate gland, may indicate cancer.

A suspicious digital exam or PSA test is often followed by an *ultrasound* examination, which uses sound waves to create a detailed image of the prostate. This image aids a doctor in obtaining small surgical samples of tissue from the gland. If the tissue is cancerous, more tests are needed to determine if the cancer is confined to the prostate or has spread elsewhere in the body.

Doctors can often cure cancer that remains confined to the prostate by radiation therapy or by surgical removal of the gland. Both treatments may interfere with a man's ability to have sexual relations or may cause *urinary incontinence* (inability to hold back urine). Surgeons have developed an operation that may avoid sexual problems by preserving nerves important in sexual

functioning. Doctors extend the lives of patients whose cancer has spread beyond the prostate gland with treatments that reduce levels of male hormones. Prostate cancer cells need male hormones to survive and grow.

Doctors recommend that middle-aged men have an annual digital rectal examination to detect any prostate cancer before it causes symptoms. Many doctors also recommend an annual PSA test, which can detect small tumors before they can be felt. Some doctors fear that this use of the PSA test will find some slow-growing cancers that would never become life-threatening. Treating such cancers may subject patients to the risks of unnecessary surgery or other procedures. But doctors cannot yet predict which tumors will become life-threatening. Marc B. Garnick

See also **Cancer; Prostate gland.**

Prostate gland, *PRAHS tayt,* is an organ of the male reproductive system. It produces a thick whitish fluid that helps transport sperm. All male mammals have some form of prostate gland. In men, this gland sits just below the urinary bladder and directly in front of the rectum. The *urethra,* the tube through which urine leaves the body, passes through the prostate. The gland weighs about $\frac{2}{3}$ ounce (20 grams) and is about the size of a walnut. It consists of muscular and glandular tissue with a tough, fibrous covering.

Sperm are produced in the testicles and travel to the prostate through two tubes called the *vas deferens.* In the prostate, the vas deferens meet the ducts of two fluid-producing glands called *seminal vesicles.* Fluids produced by the prostate gland and seminal vesicles mix with sperm to form *semen.* Semen supports sperm and helps carry them out of the body through the urethra.

Enlargement of the prostate, also called *benign prostatic hyperplasia,* is common in men over 50 years old. An enlarged prostate can squeeze the urethra and cause frequent urination, difficulty urinating, or other symptoms. Treatment of an enlarged prostate depends on its size and the extent of symptoms. Doctors sometimes treat the condition with drugs. Other treatments destroy excess tissue with heat. In some cases, surgical removal of all or part of the gland is required. Enlargement of the prostate may also be caused by cancer (see **Prostate cancer**). Earl F. Wendel

See also **Reproduction, Human.**

Prosthetics, *prahs THEHT ihks,* is a branch of medicine that deals with supplying artificial body parts. An artificial part, called a *prosthesis,* replaces a body part lost due to disease or a birth defect. A prosthesis serves one or more of three basic purposes: (1) it duplicates, as well as possible, the functions of the missing part; (2) it provides structural support for remaining tissues; and (3) it improves the person's appearance.

A set of false teeth is an example of a prosthesis that serves all three purposes. A limb prosthesis provides a functional—and in some cases, cosmetic—substitute for a missing arm or leg. Some types of prostheses are implanted within the body. For example, diseased or damaged joints, particularly of the hip and the knee, may be replaced by functional prostheses made of metal and plastic. Synthetic arteries and veins may replace blocked or ruptured blood vessels. People with heart problems may receive artificial heart valves to replace faulty ones. An artificial breast is a type of cosmetic prosthesis used by some women who have had a breast removed because of cancer.

© Catherine Karnow, Corbis

Prosthetics deals with supplying artificial parts for the body. This Cambodian worker, who lost his own legs because of a land mine explosion, is preparing leg prostheses.

Some prosthetic devices perform the function of a defective body part but do not replace the part itself. For example, an implanted electronic mechanism called a *pacemaker* regulates the beating of the heart. Other devices replace an internal organ but are attached from outside the body. One such device is a *dialysis machine,* which does the work of the kidneys. Dudley S. Childress

See also **Artificial limb; Dentistry** (Prosthodontics).

Prostitution is the performance of sexual acts for payment. It exists throughout the world, largely in urban areas. Most prostitutes are women. But prostitutes also include men and children.

Some prostitutes work for themselves. Others work for men known as *pimps* or for women called *madams.* In many countries, *call services* or houses of prostitution, often called *brothels,* connect prostitutes with clients, set fees, and protect prostitutes from dangerous or unwanted customers. Some prostitutes seek customers on streets and in other public places. Both prostitutes and their clients face a risk of contracting sexually transmitted diseases, including AIDS (see **AIDS**).

In many Western countries, much prostitution is related to drug abuse. In the United States, for example, many prostitutes sell sexual services to support a drug habit. Psychologists and social scientists believe many people in developed countries become prostitutes because they have been emotionally, physically, or sexually abused as children or as adults. In developing countries, poverty is the main reason for prostitution.

In the United States, prostitution is legal only in Nevada, where each county has the option of allowing houses of prostitution. In Canada, call services are legal. But houses of prostitution are illegal, and prostitutes may not seek customers in public. Prostitution is also legal in parts of South America and Asia. Many European cities have experimented with legal prostitution.

People in Western countries disagree about whether prostitution should be legalized. Many people oppose prostitution on moral or religious grounds. Some people think that the legalization of prostitution results in a rise in the spread of sexually transmitted diseases. But others argue that legalization controls the spread of

such diseases because it enables governments to require medical inspection of prostitutes.

Prostitution has existed throughout history. It was widespread in ancient Egypt, Greece, Rome, and China. In European and Asian history, some prostitutes have held high social rank. Michele G. Shedlin

Protactinium, *proh tak TIHN ee uhm,* is a radioactive metal belonging to the actinide series of elements. Two teams of scientists independently isolated the element in 1917. These were Otto Hahn and Lise Meitner of Germany, and Frederick Soddy and John Cranston of Britain. Protactinium occurs naturally in all uranium ores. It is also produced artificially in nuclear reactors and in particle accelerators.

Protactinium has the symbol Pa. Its atomic number is 91, and its atomic weight is 231.03588. Its most stable isotope has a half-life of 33,000 years. Several chemical compounds containing protactinium are known. Protactinium metal melts at 1572 °C. Richard L. Hahn

Protea, *PROH tee uh,* is the name for a group of about 130 species of evergreen shrubs and small trees native to Africa. They grow to a height of 3 to 10 feet (0.9 to 3 meters). Proteas bear large flowers that may vary widely

WORLD BOOK illustration by John F. Eggert

Flower heads of the giant protea grow up to 8 inches (20 centimeters) wide. The flowers can be white, pink, or red.

in size, shape, and color, depending on the species. The flower heads are surrounded by many overlapping *bracts* (leaflike structures) that may be white, pink, or red. Proteas are named after Proteus, a Greek sea god who could assume many forms.

Only a few species of proteas are cultivated. Probably the most common is the *giant protea,* also called *king protea.* This plant has flower heads that measure as much as 8 inches (20 centimeters) wide. Cultivated proteas grow best in climates with dry summers and mild, wet winters. In parts of California, they are grown commercially for their flowers. They are useful as ornamental plants.

Proteas require well-drained, slightly acid soil. They are started by planting seeds in the fall. Proteas tend to develop fungal diseases during their first year of growth unless treated with a fungicide. Kenneth A. Nicely

Scientific classification. Proteas make up the genus *Protea* in the protea family, Proteaceae. The scientific name for the giant protea is *Protea cynaroides.*

Protection of wildlife. See Wildlife conservation.

Protective coloration is coloring that protects a plant or animal from its enemies. There are several forms of protective coloration that deceive enemies or warn them away. In *cryptic coloration,* the color and color pattern of a plant or animal blend in with the surroundings so that the individual is not easily discovered. For example, the coloration of many insects, reptiles, birds, and mammals that live in the desert closely matches the color of the sand. The stone plants of South Africa look like stones. Snowshoe hares and weasels have coats of brown hair during warm months and white coats during the winter.

In *disruptive coloration,* one part of an animal's body stands out more than the other parts so that the real shape of the body is not conspicuous. For example, the killdeer, a bird that lives in fields in North America, has a bold pattern of brown-and-white crossed with black stripes. An enemy sees several brownish lumps and may not recognize the outline of the bird.

Mimicry is a form of protective coloration in which a plant or animal strongly resembles another plant or animal. *Batesian mimicry* occurs when an animal that is otherwise defenseless against a particular enemy looks like an animal that is distasteful or dangerous to that enemy. For example, the viceroy butterfly has a color pattern similar to that of the monarch butterfly, which makes birds sick when eaten.

Some forms of protective coloration

© Stouffer Productions, Ltd., from Animals Animals

Cryptic coloration allows ptarmigans to blend into their snowy surroundings.

© Carson Baldwin, Jr., Animals Animals

Warning coloration protects a skunk by reminding the animal's enemies of its ability to spray a foul-smelling liquid.

Another form of protective coloration is called *warning coloration.* A number of brightly colored insects, such as ladybugs and bumblebees, taste bad or sting. Their warning coloration reminds a predator of past experiences with those insects and frightens it away.

Protective coloration has been developed over many thousands of years. Plants and animals protected by color survived and reproduced their kind. Those that were not protected died out. This process is called *natural selection.* Edward H. Burtt, Jr.

Protective tariff. See Tariff.

Protein is one of the three main classes of food that provide energy to the body. The others are carbohydrates and fats. Proteins exist in every cell and are essential to plant and animal life. Plants build proteins from materials in the air and the soil. Human beings and animals obtain proteins from foods. Foods high in protein include cheese, eggs, fish, meat, and milk.

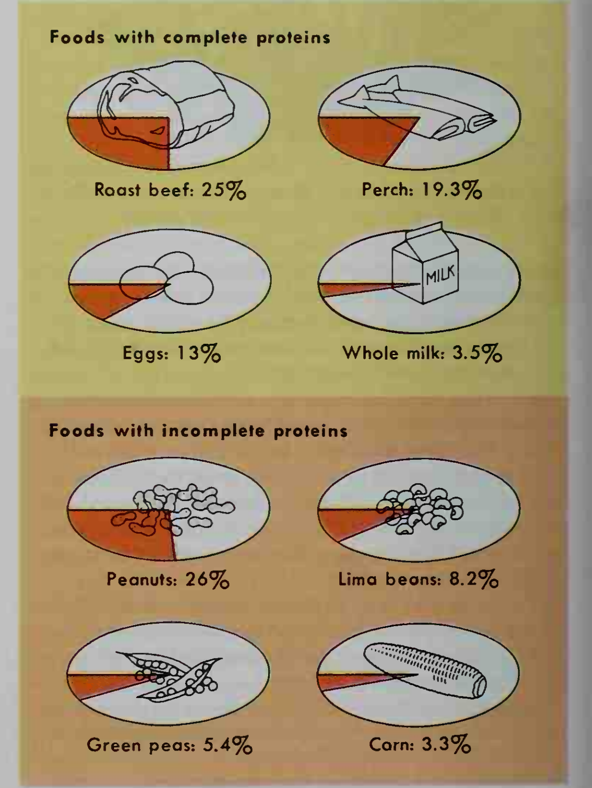
The structure of proteins. All proteins contain carbon, hydrogen, nitrogen, and oxygen. Some proteins also contain iron, phosphorus, and sulfur. Proteins are large, complex molecules made up of smaller units called *amino acids.* The amino acids are linked together into long chains called *polypeptides.* A few polypeptides are straight, but most are bent into complex three-dimensional shapes. A protein consists of one or more polypeptide chains.

Twenty common amino acids are assembled into the thousands of different proteins required by the human body. To assemble the proteins it needs, the body must have a sufficient supply of all these amino acids. Nine amino acids, called *essential amino acids,* either cannot be produced by the body, or are produced, but in insufficient amounts. Therefore, they must be supplied by various foods. The remaining amino acids, called *nonessential amino acids,* can be manufactured by the body in sufficient amounts.

Proteins in the diet. The best sources of proteins are cheese, eggs, fish, meat, and milk. The proteins in these foods are called *complete proteins* because they contain adequate amounts of all the essential amino acids. Cereal grains, *legumes* (plants of the pea family), nuts, and vegetables also supply proteins. These proteins are called *incomplete proteins* because they lack adequate amounts of one or more of the essential amino acids. However, a combination of two incomplete proteins can provide a complete amino acid mixture. To do so, each incomplete protein must have sufficient amounts of the essential amino acids of which the other incomplete protein contains small amounts. For example, a cereal grain, such as barley or corn, could be combined with a legume, such as peas or peanuts. The foods must be eaten together to provide the correct balance of amino acids.

In the United States, the Recommended Daily Dietary Allowance of protein for adults is 0.8 gram per kilogram (0.013 ounce per pound) of body weight. Infants and children need extra protein, as do pregnant women and nursing mothers.

Insufficient protein in the diet may cause lack of energy, stunted growth, and lowered resistance to disease. A protein shortage also may lead to *edema,* a condition in which fluids accumulate in body tissues, causing the tissues to swell. In developing countries, many infants and children have a disease called *kwashiorkor* as a result of eating little or no food containing complete proteins. Severe cases of kwashiorkor may cause liver damage and eventual death. See **Kwashiorkor**.



How the body uses proteins. Proteins make up a large part of each cell in the human body. Therefore, they are important in building, maintaining, and repairing tissues in the human body, especially bone cartilage and muscle.

In addition, every cell contains proteins called *enzymes,* which speed up chemical reactions. Without enzymes, the cells could not function. Certain proteins perform specific jobs. For example, the blood contains such proteins as *albumin* and *hemoglobin.* Albumin helps maintain the body's fluid balance by keeping water in the blood. Hemoglobin carries oxygen from the lungs to body tissues. *Antibodies* are proteins in the blood that help protect the body from disease. Chemical sub-

Protein content of selected foods

Foods vary in the amount and kind of protein they contain. Those with *complete proteins* provide enough of all the essential amino acids. Foods with *incomplete proteins* lack enough of one or more of these amino acids. But correct combinations of incomplete proteins can provide a balanced amino acid mixture.

WORLD BOOK diagram by David Cunningham

stances called *hormones,* many of which are proteins, control such processes as growth, development, and reproduction.

The body obtains most of its energy from carbohydrates and fats. However, the body uses proteins for energy when carbohydrates and fats cannot meet its energy needs. Proteins produce about 1,800 calories of energy per pound (4 calories per gram), the same amount provided by carbohydrates.

After proteins have been eaten, hydrochloric acid, which most people have in their stomach, causes the protein molecules to *coagulate* (thicken and clump together). Enzymes in the stomach and in the intestines break down the coagulated proteins into individual amino acids. The amino acids are absorbed into the blood and travel throughout the body. Every cell assembles the amino acids into the proteins it needs. This process is controlled by *DNA* (deoxyribonucleic acid), a substance in the nucleus of each cell. For a detailed description of how a cell produces proteins, see **Cell** (Producing proteins; The code of life).

Food containing proteins should be included in the daily diet because the body cannot store proteins for later use. The body converts excess proteins into carbohydrates and fats. If the body does not receive enough proteins from the food eaten, it uses proteins from the cells of liver and muscle tissues. However, continued use of such proteins by the body can permanently damage those tissues. Richard A. Ahrens

Protestant ethic is a set of attitudes that stress the moral value of work, self-discipline, and personal responsibility. These principles developed from the Protestant belief that people do not live and work for themselves alone. People's work—or their *calling,* as it is sometimes termed—comes from God. People prove their worth to themselves, to their society, and to God by overcoming hardship through dedicated achievement, self-control, and moral living.

The Protestant ethic encourages people to work because of the belief that work is good. The ethic emphasizes self-denial to promote thrift, and it discourages spending large amounts of money for luxuries or personal pleasures. It also holds that unnecessary comforts distract people from their duty to God. The ethic does not view wealth as evil in itself. Wealth becomes evil only when it tempts people to idleness and sinfulness.

Personal responsibility ranks as one of the most important ideals of the Protestant ethic. For example, dedication, foresight, and thoughtfulness help a person succeed. The ability to resist temptation keeps a person from wasting energy, savings, and time. According to the ethic, a person is good if he or she is hard-working, honest, and thrifty. Such a person is more virtuous than one who is lazy, pleasure-seeking, and wasteful.

The concept of the Protestant ethic is closely associated with Max Weber, a German sociologist. In 1904 and 1905, Weber wrote a famous essay called "The Protestant Ethic and the Spirit of Capitalism." He maintained in this essay that the principles of the Protestant ethic contributed to the development of the economic system called *capitalism.* In capitalism, individuals and corporations control and direct the means of production. The hard work, investments, and savings of individuals help build a capitalist economy. Neil J. Smelser

See also **Reformation** (Political and social influences); **Weber, Max.**

Protestantism is the general name for hundreds of Christian denominations and sects that differ slightly or greatly from one another. About 380 million people—about 7 percent of the world's population—belong to these various groups. Among Christian bodies, only the Roman Catholic Church has more members.

Protestantism resulted chiefly from the Reformation, a religious and political movement that began in Europe in the early 1500's. The word *Protestant* comes from the Latin word *protestans,* which means *one who protests.* It was first used in 1529 at a *diet* (formal assembly) in Speyer, Germany. At the diet, several German leaders protested an attempt by Roman Catholics to limit the practice of Lutheranism, an early Protestant movement. The leaders became known as Protestants. The name soon came to include all of the Western Christians who had left the Roman Catholic Church.

Most Protestants live in Europe and North America, but the number of Protestants is increasing in such areas as Africa and Latin America. A Protestant denomination is the state religion of a number of nations, including Denmark, Norway, Sweden, and the United Kingdom. Protestantism has strongly influenced the cultural, political, and social history of these and other countries.

Protestant beliefs

Protestants share most Christian beliefs with members of the Roman Catholic and Eastern Orthodox churches. For example, Protestants believe there is only one God. Most members of Protestant denominations also believe that in God there are three Persons who together form the *Trinity.* These Persons are the Father; the Son, who is Jesus Christ; and the Holy Spirit. Protestants also believe in the central importance of Christ as the savior of humanity.

Historically, Protestants have disagreed most with other Christians over the ways human beings relate to God. As a result of this disagreement, Protestants have developed distinctive beliefs in certain areas. Two prominent Protestant beliefs involve (1) the nature of faith in God and the nature of the grace of God and (2) the authority of the Bible.

Faith and grace. Protestants oppose the Roman Catholic doctrine on salvation. Catholics believe that people achieve salvation by having faith in God's grace and by their own merit—that is, by doing good works. Protestants also stress the importance of faith, but reject the emphasis that Catholics place on good works.

According to Protestantism, God is first of all gracious—that is, He is loving and forgiving. He establishes and is responsible for His relationship with people. Protestants believe people are incapable of saving themselves because of their sins. Therefore, they are saved by the grace of God and not by their own merit. Protestants believe this grace of God comes to people through Christ. They regard Christ's death on the cross as a gift of God's grace. But this grace comes to those who have faith, not to those who do good works. Thus, people receive salvation by having faith in God's grace, which comes to them through Christ.

The authority of the Bible. The beliefs of Roman Catholics are based on both the Bible and the traditions of their church. These traditions come from the declarations of church councils and popes. They also come from short statements called *creeds* and from longer, formal statements called *dogmas.* Protestants, on the other hand, reject the idea that the pope should be the highest earthly Christian authority. Most Protestants believe that the Bible should be the only authority for their religion.

Through the centuries, several Protestant denominations have based their beliefs on other authorities in addition to the Bible. For example, certain churches believe that personal religious experience serves as a measure of their faith. Others believe they can test their faith through human reason or certain church traditions. But in general, the Bible remains the central religious authority for Protestants.

Worship and liturgy

Protestants worship only one God. But various denominations worship God in greatly different ways. Protestant *liturgies* (worship services) range from the simple, informal meetings of the Quakers to the elaborate ceremonies of certain Anglican churches. But despite many differences, most Protestant liturgies share such basic features as (1) faith in the word of God, (2) belief in sacraments, and (3) the importance of the laity.

Faith in the word of God. Most Protestant liturgies stress preaching and hearing the word of God. Protestants believe that God is present in their midst and inspires faith in them when they discuss, hear, and read the Bible. For this reason, most Protestant services focus attention on the preacher and the sermon.

Belief in sacraments. Various Protestant denominations disagree about the nature and number of solemn observances called *sacraments.* But most denominations include at least two sacraments—Baptism and the Lord's Supper—in their worship.

Baptism is a sacrament that, for some Protestants, represents the beginning of Christian life, so it can occur with infants. Others view baptism as a sign of a person's faith, in which case the person must be old enough to reason about its meaning. Most Christians connect baptism with God's gift of faith and grace.

The Lord's Supper, or Communion, is a ceremony that recalls Christ's words and actions at the Last Supper. Protestants believe that it either represents or expresses God's forgiveness of sinners.

The importance of the laity. Most Protestant churches stress the role of the *laity,* church members who are not clergy. Protestantism expects these people to participate in the liturgy through singing and prayer, and often encourages them to participate in the leading of worship and even to preach. Such participation establishes a sense of community in which God's word may be heard and His relationship to humanity understood.

History

Most Protestant denominations originated during the Reformation. But some, such as the Moravian Church, were beginning to take shape before the Reformation. The Reformation itself began in 1517 when Martin Luther, a German monk, protested certain practices of the Roman Catholic Church. By about 1550, Protestantism had spread throughout almost half of Europe. See **Reformation; Roman Catholic Church** (The Reformation and Counter Reformation).

Protestantism developed as a series of semi-independent religious movements. These movements resembled one another in their rejection of the central authority of the pope. But cultural, geographic, political, and religious differences caused them to develop independently in varying degrees. Many such differences resulted in the division of the larger movement into various denominations and sects.

Despite their differences, the various resulting Protestant movements can be divided historically into five general groups. These groups are (1) the conservative reform movements, (2) the radical reform movements, (3) the free church movements, (4) the Methodist movement, and (5) the unity movement.

The conservative reform movements (the 1500's). These movements include groups that broke away from the Roman Catholic Church but kept many basic beliefs of that church. Among such movements, in order of their establishment, are the Lutheran; the Reformed, or Presbyterian; and the Anglican, or Episcopalian.

The Lutheran movement, based on the teachings of Martin Luther, was the earliest major Protestant movement. It spread rapidly throughout northern Germany and the Scandinavian nations during the 1520's. Lutherans largely agreed on the importance of faith and the authority of the Bible. But they disagreed widely over the form of the liturgy and church government. These disagreements led Lutherans to split into several factions.

The Reformed, or Presbyterian, movement developed largely from the teachings of two reformers, Huldreich Zwingli and John Calvin. During the 1520's, Zwingli, a Swiss priest, urged reforms that were more radical than Luther's. In the 1530's, the French reformer John Calvin largely combined the ideas of Luther and Zwingli. Calvin's teachings strongly influenced people in England, France, the Netherlands, and Scotland. In England, many of his followers became known as *Puritans.* In France, they were called *Huguenots.* The Scottish reformer John Knox introduced Calvin's teachings in Scotland.

The Anglican, or Episcopalian, movement started in England. It resulted from the Act of Supremacy of 1534, in which King Henry VIII declared his independence from the pope. The Anglican Church became established in England only after much dispute and bloodshed. In 1559, Queen Elizabeth I established a moderate form of Protestantism that became known as Anglicanism.

The radical reform movements (the 1500's and 1600's). Some small religious sects differed widely from both the Roman Catholic Church and major Protestant churches. Most of these radical groups thought conservative Protestants had not reformed the Catholic Church enough. Many of the sects rejected conservative reforms and developed their own forms of worship.

The Anabaptists and other radical groups first appeared during the Reformation. Other radical sects developed in Europe and North America after the Reformation. They included the Quakers, the Separatists, and the Shakers.

The free church movements (the 1500's and 1600's). This group consisted of two movements, the Congregational and the Baptist. They developed chiefly from rigorous reform movements that came to be called Puritan. They took shape in early Reformation times.

During the late 1500's in England, various Puritans opposed certain policies of the Anglican Church. They believed they could not reform the church from within, and so they separated from it. This separation resulted in their being called *Separatists.* But they soon became known as *Congregationalists* because of their belief in the rights of local congregations.

In the early 1600's, an English clergyman named John Smyth led a group of Separatists to the Netherlands. He and his followers believed that only people who were old enough to express their faith should be baptized. Smyth's group became known as *Baptists.*

The free church movements spread into colonial America. The Pilgrims, a separatist group led by William Brewster, established the Plymouth Colony in 1620. In 1638, the religious leader Roger Williams founded a Baptist church in Providence in the Rhode Island Colony. By the 1920's, the Baptist Church ranked as the largest Protestant denomination in the United States.

The Methodist movement (the 1700's). Methodism developed largely from *pietism,* a religious attitude that began in Europe during the late 1600's. Pietism stressed the importance of personal devotion and morality as the most profound expressions of faith.

In the early 1700's, John Wesley, an English clergyman, set out to reform the Anglican Church, also known as the Church of England. Wesley preached doctrines that were *evangelical*—that is, they emphasized the need for personal religious experience. He was not satisfied by the Anglican response to his reform and, in 1744, he organized the Methodist movement. Methodism grew rapidly in England and, later, in the United States.

Pietism and various evangelical churches greatly influenced other Protestant denominations. Many missionary movements began, and Protestantism had spread throughout the world by 1900.

The more conservative and enthusiastic branches of Methodism gave birth to the Holiness movement, including the Nazarenes. In the early 1900's, the Holiness movement, in turn, inspired a movement called Pentecostalism. Pentecostalism has become one of the most rapidly growing forms of Protestantism. The Pentecostals are sometimes called *charismatics.*

The unity movement (the 1800's and 1900's). Since the mid-1800's, many Protestants and other Christians have shown an increasing desire to overcome their differences. They have sought to unite various Protestant denominations and to encourage cooperation through federations and councils. In addition, many of these people have worked to increase good will among Protestants and members of the Eastern Orthodox and Roman Catholic churches.

In 1846, a group in London formed the Evangelical Alliance to give individual Christians an opportunity to unite in friendship and discussion. During the early 1900's, the trend toward Christian unity became known as the *ecumenical movement.* Representatives of different Protestant denominations met with one another, as did representatives of Protestant churches and the Eastern Orthodox Churches. In 1948, church leaders founded the World Council of Churches. This organization works for cooperation and unity among all the churches of the world.

In 1965, Pope Paul VI expressed the need for unity among all Christians. He made the statement at the end of an ecumenical council called Vatican Council II. Many Protestants and other Christians welcomed the pope's expression of unity and the unifying spirit of the council itself. Martin E. Marty

Protist, *PROH tihst,* is the name of a group of organisms, most of which are microscopic. The group consists chiefly of such one-celled organisms as diatoms, protozoans, and certain algae. Protists make up the Protista, which is one of the five biological kingdoms of living organisms. The other kingdoms are Prokaryotae (prokaryotes), Fungi (fungi), Plantae (plants), and Animalia (animals).

The German zoologist Ernst H. Haeckel first proposed the idea of Protista in 1866. He included the organisms fungi and sponges in the group. Today, many biologists limit the kingdom to one-celled organisms that have a well-defined nucleus and typical *organelles.* Organelles are organlike structures that perform specialized functions. Many biologists classify one-celled organisms that lack a well-defined nucleus or typical organelles in the Prokaryotae kingdom. Most protists reproduce by *mitosis,* a process by which one cell divides into two separate cells. Some reproduce sexually. Irwin Richard Isquith

See also **Algae; Diatom; Euglena; Kingdom; Protozoan; Prokaryote.**

Protocol, *PROH tuh kahl,* is a document containing a record of talks carried on by diplomatic representatives. The document shows that the diplomats have agreed on important issues. A protocol is an official government paper, but it does not have the force of a treaty until ratified by the governments concerned (see **Treaty**). The term *protocol* also means the official etiquette of state ceremonies. Robert J. Pranger

Proton, *PROH tahn,* is a positively charged subatomic particle. A single proton constitutes the nucleus of an ordinary hydrogen atom. Protons, together with other subatomic particles called *neutrons,* make up the nuclei of all other atoms (see **Neutron**). All atoms of the same chemical element have the same number of protons. The number of protons in the atoms is called the *atomic number* of the element.

Ordinarily, an atom has an equal number of protons and *electrons,* negatively charged particles that surround the nucleus. Each proton carries one unit of positive charge, and each electron carries one unit of negative charge. As a result, the atom is electrically neutral.

Protons are made up of fundamental particles called *quarks* (see **Quark**). A proton has a diameter of approximately one millionth of a nanometer. One nanometer equals one millionth of a millimeter ($\frac{1}{25,400,000}$ inch). The mass of a proton in grams may be written with a decimal point followed by 23 zeros and a 2.

The proton was first identified by the German physicist Wilhelm Wien in 1902, and its identity was proved by the British physicist Sir Joseph J. Thomson in 1906. Scientists initially believed that protons would not naturally *decay* (break down) into other particles. However, mathematical *grand unified theories,* introduced in the mid-1970's, offered new insights about the fundamental forces that affect atoms and their nuclei. These theories predict protons can decay. Experiments to detect this decay are underway. Edward S. Fry

See also **Atom; Baryon; Electron; Gluon; Subatomic particle.**

Protoplasm, *PROH tuh PLAZ uhm,* is a term that means the living matter of cells. The term is little used by modern biologists because it is not specific. Johannes Purkinje, a Czech physiologist, first used it in 1839. At that time, scientists knew that all living things are made up of cells that seemed to contain a jellylike material. Purkinje named this material *protoplasm*—from Greek words meaning *first formed* or *molded*—to indicate it was the most basic substance of life.

Since that time, more powerful microscopes and advanced biochemical techniques have revealed more about the structure of the cell. Scientists have discovered that the jellylike material of cells is actually a complex mixture of proteins and other substances. The composition of this mixture varies among different types of cells and even from one part of a cell to another. Thus, biologists today use the terms *cytoplasm, nucleoplasm,* and *plasma membrane* to describe specific parts of the living cell matter (see **Cell** [Inside a living cell]). However, the word *protoplasm* is still sometimes used to describe the substance of a type of slime mold lacking cell boundaries at one stage of its life cycle.

Mary Lee S. Ledbetter

Protozoan, *PROH tuh ZOH ahn,* is a one-celled organism that may have plantlike or animallike characteristics. Scientists traditionally classified protozoans as animals and placed them in the phylum Protozoa. Today, however, many scientists group protozoans as neither animals nor plants. They place protozoans with other simple organisms in the kingdom Protista (see **Protist**). The study of protozoans is called *protozoology.*

Characteristics of protozoans

There are over 30,000 kinds of protozoans, most of them so small that they can be seen only through a

microscope. Protozoans live in moist places. They are found in salt water, fresh water, soil, plants, and animals.

Structure. The *ameba* is one of the simplest protozoans. The single cell that makes up its body carries on all the necessary life processes by itself. The cell eats, breathes, and responds to its surroundings.

Other protozoans are more complicated in structure. Some of them, called *ciliates,* have tiny hairlike projections that help them move about. The *paramecium* has a definite groove on one side that serves as a mouth.

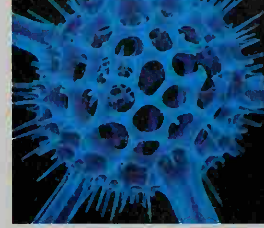
Some protozoans have a bright red spot called the *eyespot.* This spot may be sensitive to light.

The bodies of some protozoans contain chlorophyll, the green substance also found in plants. Chlorophyll enables these protozoans to make their own food (see **Photosynthesis**).

Reproduction. Some protozoans reproduce by a process called *fission.* In this process, the original cell splits in two. Each half of the original cell becomes a separate individual. In other protozoans, the parent cell suddenly swells in one direction. The swollen part breaks off and forms a new protozoan. This process is called *budding.* Certain protozoans reproduce by dividing into many cells called *spores.* Other protozoans show the beginnings of sexual reproduction. In all these forms of reproduction, the cell's nucleus is divided among the new individuals. See **Reproduction**.

Importance. In spite of their small size, protozoans are very useful for both human beings and animals. Millions of protozoans swim in the sea, where they are eaten by sea animals. Some protozoans, such as the foraminifers, are covered with stony shells. When they die, they settle to the bottom of the ocean and contribute to the formation of limestone. The fossil shells of such protozoans are partly responsible for the chalk cliffs that are found in southern England.

Many protozoans are serious enemies of human beings and animals. Malaria and African sleeping sickness are among the diseases they cause.



Types of protozoans

Protozoans can be placed into four groups on the basis of how they move: (1) flagellates, which have one or more whiplike *flagella;* (2) sarcodines, which include the amebalike protozoans; (3) apicomplexans, which move by gliding; and (4) ciliates, which have many hairlike *cilia.*

A ciliate

Types of protozoans

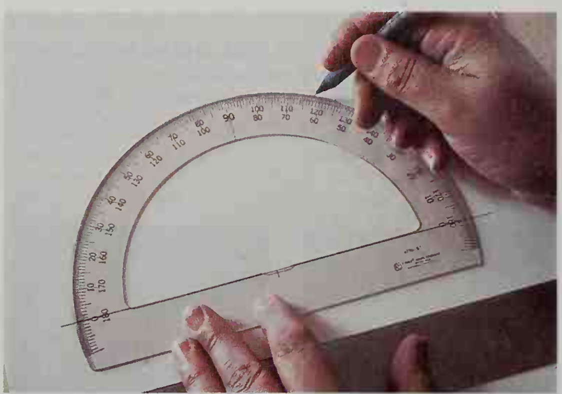
Protozoans can be divided into four groups on the basis of how they move about. These groups are (1) flagellates, (2) sarcodines, (3) apicomplexans, and (4) ciliates.

Flagellates have one or more long hairlike projections from their bodies called *flagella.* The flagella whip about rapidly to move the flagellate through the water. Flagellates are usually oval in shape, and many have chlorophyll in their bodies. The green *euglena* is shaped much like a submarine. It is common in fresh water. The *volvox* is a green ball of flagellated cells that live together. This ball moves about when the flagella of the individual members that make it up are whipped in the water. The *trypanosomes,* which cause African sleeping sickness, are also flagellates.

Sarcodines move by extending fingerlike *pseudopods* (false feet). A sarcodine forms these structures by pushing out its membrane. Sarcodines also use pseudopods to capture food. Sarcodines include the amebas and other amebalike protozoans. Many of the amebas live in the bodies of human beings and animals. Some cause disease, and others do not. For example, the harmless colon ameba is found in the large intestine of many healthy people.

Radiolaria are among this group of amebalike protozoans. Radiolarians have a tiny skeleton that is made of silica. After a radiolarian dies, this skeleton sinks to the ocean floor. Millions of shells have accumulated in parts of the ocean, forming thick layers of ooze. The *foraminifers* have shells made of chalklike material. Some of the ancient foraminifers were almost as large as a quarter. Geologists seeking oil study foraminifer fossil shells in rocks found below the surface. They indicate how the earth layers are arranged.

Apicomplexans make up a special group of protozoans that move by gliding. Protozoans of this type live as parasites. The malarial parasite is a well-known apicomplexan.



Ciliates are the most complex protozoans. All of them have, at one time or another, fine hairlike projections, which are called *cilia.* The cilia help the ciliates move about to capture food. The *stentors,* which are shaped something like a horn or trumpet, rank among the largest of all of the protozoans. Another kind of ciliate, the *vorticella,* looks something like a funnel with a long tube. The vorticella creates a little whirlpool around the top of the funnel to draw food into its body.

A student uses a protractor to draw an angle.

Protractor is a device for measuring the size of angles or drawing angles of specified sizes. Protractors are made of plastic, paper, or metal. Most protractors are shaped like the letter D, with the arc in the shape of a semicircle. Lines and numbers on the arc indicate angles from 0 to 180 degrees (or, in some cases, from 0 to 3,200 mils).

To measure an angle, a straight edge of the protractor—or a line printed on it—is placed along one line of the angle. The reading is made where the other line crosses the arc. Full-circle protractors can read from 0 to 360 degrees. Todd I. Blue

Proudhon, *PROO DAWN,* **Pierre Joseph,** *pyair zhoh ZEHF* (1809-1865), was a French socialist, writer, and critic. In 1837, he published his *Essay on General Grammar.* This work won him a three-year pension from the Academy of Besançon. However, in 1840, Proudhon's *What Is Property?* lost him the academy's approval. The work revealed his socialistic ideas, and stated that "property is theft." Proudhon objected to the use of property to exploit the labor of others.

Proudhon wrote many other influential works, including *System of Economical Contradictions: or, The Philosophy of Misery* (1846). His radical ideas and political activities often led to trouble with the French government. As a result, he spent a number of years in prison and in exile. While in prison, he wrote several books.

Ideas. In 1848, Proudhon declared that his main inspirations were the Bible, the German philosopher G. W. F. Hegel, and the British economist Adam Smith. Proudhon was enthusiastic about the ideas of liberty, justice, and equality. His idea of liberty implied the rejection of all authority, except for that in the family. Unlike many other socialist writers, he had little use for the powers of government. He was an *anarchist*—that is, a believer in a social order without government (see **Anarchism**). Proudhon referred to his beliefs as *mutualist socialism.*

Proudhon argued that society should operate by means of contracts. These contracts should be voluntary agreements among free and equal peoples. He believed that contracts would establish a system of mutual rights and duties, which would result in justice.

In some of his works, Proudhon favored cooperation between working people and small proprietors. Such cooperation, he believed, would be more likely to bring about liberty, justice, and equality than would any action by the government.

Proudhon's work is not always consistent and is sometimes difficult to interpret. For instance, he urged equality, yet believed in the existence of inferior races and opposed increased political and social rights for women. His views often conflicted with those of other socialists, including the German social philosopher Karl Marx.

Early life. Proudhon was born in Mouillére, near Besançon, on Jan. 15, 1809. He studied at the College of Besançon. From 1843 to 1847, he worked in a printing plant in Lyon. He moved to Paris in 1848. Stephen Schneck

Proust, *proost,* **Joseph Louis,** *zhoh ZEHF lwee* (1754-1826), was a French chemist. He became known for helping prove the idea that every pure chemical compound consists of elements in a definite proportion. Today, scientists accept this idea as the *law of constant proportions.* In Proust's day, chemists disagreed on whether the proportion of elements in a compound was definite. Claude L. Berthollet, an influential French chemist, debated Proust for years on the subject in the early 1800's. Chemists accepted Proust's evidence as correct by about 1808.

Proust was born on Sept. 26, 1754, in Angers, France. When in his 30's, he moved to Spain. There, he taught chemistry in several universities and experimented in many areas of chemistry. He developed ways of obtaining sugar from grapes and did other research on foods. M. J. Nye

Proust, *proost,* **Marcel,** *mar SEHL* (1871-1922), was a French author. His seven-part novel *Á la recherche du temps perdu,* known in English as *Remembrance of Things Past,* is a masterpiece of literature. The novel's title has also been translated as *In Search of Lost Time.* It consists of *Swann's Way, Within a Budding Grove, The Guermantes Way, Cities of the Plain, The Captive, The Sweet Cheat Gone,* and *The Past Recaptured.*

Remembrance of Things Past is filled with vivid characters and provides a panorama of French high society in the process of change. It is a study of love, jealousy, marriage, and the evils of the age and describes the growth of the narrator, Marcel, into a mature artist. Marcel, except in one episode, is both participant and observer. He tells his story with frankness, intelligence, sensitivity, irony, and humor. The work has brilliant dialogue and offers original and profound observations about music, art, writing, theater, and criticism. Proust compared the novel's structure to that of a cathedral, whose diverse parts form a whole, or that of a musical composition in which themes are introduced, abandoned, and resumed.

To Marcel, reality remains elusive. It is constantly changing, because the passing of time alters not only his own perspective, but also the nature of what is perceived. He finally recognizes that reality is not external but something stored in the depths of one's unconscious memory. There it is preserved from the changes of time, but is accessible only in rare and happy moments. These moments are made possible by a variety of sensual experiences. The most famous example is that of the "madeleine," a small cake that brings back his childhood when he dips the cake into a cup of tea and tastes it. This enables him to live two moments in time together, and this defeats time itself. Artists can reveal

reality to humanity because their sensitivity lets them dig deeply into their own unconscious memory.

Proust began writing *Remembrance of Things Past* in 1908, but he could not find a publisher. He finally published *Swann's Way* in 1913 at his own expense. Both the author's poor health and World War I delayed the publication of later volumes until 1918. Proust continually revised the novel, and the last three parts were not published until after his death.

Proust was born in Paris. During the 1890's, he wrote stories and magazine articles that were noted for their elegant but artificial style. His unfinished novel, *Jean Santeuil* (1895-1899, published 1952), has characters and incidents that foreshadow his major novel. *Contre Sainte-Beuve* (1908-1910, published 1954) is a collection of critical essays that reveals Proust as a highly sensitive critic with theories on the arts that were far in advance of his time. Elaine D. Cancalon

Proverb, *PRAHV urb,* is a brief saying that presents a truth or some bit of useful wisdom. It is usually based on common sense or practical experience. The effect of a proverb is to make the wisdom it tells seem to be self-evident. The same proverb often occurs among several different peoples. True proverbs are sayings that have been passed from generation to generation primarily by word of mouth. They may also have been put into written form. The Book of Proverbs in the Hebrew Bible, or Old Testament, is the most notable collection of such sayings. They include:

Hope deferred maketh the heart sick.
A good name is rather to be chosen than great riches.
A soft answer turneth away wrath.
Pride goeth before destruction, and
a haughty spirit before a fall.

Proverbs often find their way into literature. Many of the lower-class characters in *The Canterbury Tales* (late 1300's) by Geoffrey Chaucer refer to proverbs. Miguel de Cervantes' novel *Don Quixote* (1605, 1615) contains many proverbs. Cervantes collected the proverbs from the Spanish peasants, who supposedly could carry on a sensible conversation for a whole evening in nothing but proverbs (see **Don Quixote**).

Benjamin Franklin used many proverbial expressions in his *Poor Richard's Almanac,* issued every year from 1733 to 1758. Franklin wrote many of them himself, and took the rest from other sources. Many are still quoted (see **Poor Richard's Almanac**). Marcus Klein

See also **Epigram.**

Proverbs, Book of, is a book of the Hebrew Bible, or Old Testament. It is also known as the *Proverbs of Solomon* because, according to tradition, King Solomon wrote it. However, scholars believe that the book's assortment of moral and religious sayings, poems, and warnings come from various periods in the history of ancient Israel. They were probably not collected in their present form until after the period of the Babylonian Exile, which ended in 538 B.C.

The Book of Proverbs is a product of the educational system of ancient Israel. Children were educated primarily at home. The instructional value of many sections of Proverbs reflects the teachings of parents trying to raise their children to become successful and responsible adults. Other sections of the Book of Proverbs may come from a palace school for the training of government officials. The Book of Proverbs has earned universal appeal because it contains material valuable to all people who hope to live a life of wisdom, honesty, responsibility, self-control, and respect for God. Many of the book's sayings have become part of everyday speech. Carol L. Meyers

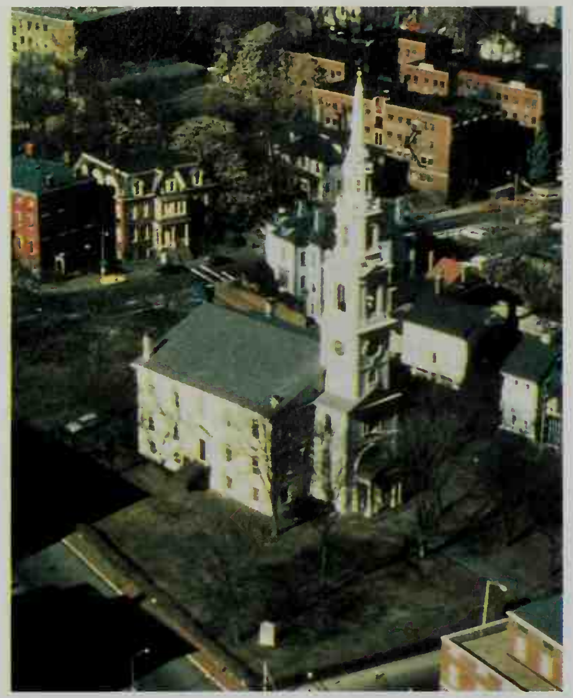
Providence, *PRAHV ih duhns* (pop. 173,618) is the capital and largest city of Rhode Island. About a sixth of the state's people live in Providence, a major New England manufacturing center. Providence lies at the head of Narragansett Bay, in the east central part of the state. For location, see **Rhode Island** (political map).

Roger Williams, a religious leader in the American Colonies, founded Providence in 1636. The settlement was the first Rhode Island community founded by the colonists. Williams named it Providence because he believed God had guided him there. See **Williams, Roger.**

Description. Providence, the county seat of Providence County, covers about 20 square miles (52 square kilometers). Providence, Fall River, Massachusetts, and Warwick form a metropolitan area of about 1,141 square miles (2,955 square kilometers) with 1,188,613 people.



Providence is the home of Brown University, which was chartered in 1764 and ranks as one of the nation's oldest colleges. Other colleges in Providence include Providence College, Rhode Island College, Johnson & Wales University, and a campus of the University of Rhode Island. The Rhode Island School of Design, nationally known for its work in textile and industrial design, owns the Museum of Art. Public art galleries include the Wheeler Gallery and Brown University's List Art Gallery. The Rhode Island Philharmonic Orchestra performs at the Providence Performing Arts Center. The Trinity Square Repertory Company presents plays at the Lederer Theater.

Providence has preserved many colonial buildings. The John Brown House, built in 1786, serves as headquarters of the Rhode Island Historical Society. The house of Stephen Hopkins, a signer of the Declaration of Independence, dates from about 1743. The First Baptist Meeting House, built in 1775, is the oldest Baptist church in the United States. The Old State House was the meeting place of Rhode Island's General Assembly from 1762 until the present State House opened on Jan. 1, 1901. The State House, made of white marble, has a dome that is 50 feet (15 meters) in diameter. Only St. Peter's Basilica in Rome has a larger unsupported marble dome. See **Rhode Island** (picture: The State House).

Roger Williams Park, the largest of the city's 35 parks, covers about 430 acres (175 hectares). The Roger Williams Park includes a museum of natural history, a zoo, and a planetarium.

Economy. The metropolitan area has over 2,000 manufacturing plants. The plants employ about 90,000 people and produce much of the world's jewelry, especially costume jewelry. The area's other products include electronic devices, marine equipment, nonelectrical machinery, primary metals, scientific instruments, silverware, textiles, and wire and cable.

Freight and passenger railroads serve Providence.

Rhode Island Department of Economic Development

The oldest Baptist church in the United States is in Providence. The building was completed in 1775 and serves as the meeting house of a congregation founded in 1639.

The Theodore Francis Green State Airport lies south of the city. Activity at Providence's port fell sharply in the late 1980's. Providence has one daily newspaper, *The Providence Journal-Bulletin.*

Government and history. Providence has a mayor-council form of government. The mayor serves a four-year term. The council consists of 15 members, each of whom serves for four years.

Roger Williams founded Providence in 1636. He had been forced to leave the Massachusetts Bay Colony because he disagreed with its rules on religion. Williams established Providence as the only settlement in the American Colonies that assured religious freedom.

In 1775, about 4,300 people lived in Providence. The first hand-operated cotton-spinning device in the United States was built there in 1787. In 1790, in nearby Pawtucket, Samuel Slater, a textile worker from England, built the first water-powered machines for spinning cotton in the United States. These events helped start the U.S. textile industry, and Providence became one of its centers.

The city's jewelry industry began in 1794, when Nehemiah Dodge, a Providence businessman, found a way to cover cheap metals with precious metals. The textile industry expanded through the years, aided by large markets in Boston and New York City. By 1880, the population of Providence had grown to 104,857. Providence received a city charter in 1832. It served as one of several capitals of Rhode Island from 1663 until 1900, when it became the state's only capital.

Providence industries prospered during World War I (1914-1918) and World War II (1939-1945). Their factories made military supplies and other war materials, and Providence shipyards built combat and cargo ships. In the 1920's, many Providence textile plants moved to the South to take advantage of lower labor and transportation costs. Many other textile plants left the city in the mid-1900's, and Providence's population fell from 248,674 in 1950 to 156,804 in 1980. But after 1980, the population began to increase again gradually.

During the 1970's, Providence began to rebuild its downtown area. The first project, called Weybosset Hill, was completed in 1981. It covered 27 blocks and included apartment and office buildings and the Civic Center. The Civic Center houses a sports arena, convention center, and exhibition hall. The downtown Capital Center Project is expected to be completed by the early 2000's. A major highway interchange, shops, office and apartment buildings, a boulevard around downtown, hotels, a convention center, and a shopping mall have been built. Stanford E. Demars

For the monthly weather in Providence, see **Rhode Island** (Climate).

Province, in Roman times, was a conquered district ruled by an official from Rome. Later, independent countries that united to form a state frequently called themselves provinces. An example is the United Provinces of Holland. Still later, independent countries were divided into provinces.

In North America, the term *province* usually refers to one of the political divisions of Canada. There are 10 of these provinces. Each has its own local government. Canadian provinces perform much the same functions as American states.

See also **Canada, Government of** (Provincial and territorial governments); **Charter.**

Provincetown. See **Mayflower; Cape Cod.**

Provisional government is a temporary government frequently set up during or after a revolution or other disorder. Provisional governments are usually established because of a breakdown or rejection of the previous constitutional system. They are intended to facilitate the establishment of another constitutional government. Alexander J. Groth

Provo, *PROH voh* (pop. 105,166), is one of the largest cities in Utah. Provo was named for Étienne Provost, an early fur trapper. The city lies at the foot of the Wasatch Range, at an altitude of 4,549 feet (1,387 meters), and overlooks Utah Lake to the west. Provo is about 40 miles (64 kilometers) south of Salt Lake City (see **Utah** [political map]). Provo and nearby Orem form the heart of a metropolitan area with a population of 368,536.

Provo is the seat of Utah County, an industrial and agricultural region. The Geneva Steel plant is near the city. Many computer software companies have their headquarters in the Provo-Orem area. Provo is the home of Brigham Young University. The city's week-long Fourth of July celebration is one of the nation's largest and oldest patriotic festivals. Ute Indians first occupied the area. In September 1776, a party of exploring missionaries led by Father Silvestre Escalante, a Spanish priest, mapped the area. Provo was founded in 1849 by Mormon pioneers. The city has a mayor-council form of government. Dale J. Stevens

Proxmire, *PRAHKS my uhr,* **William** (1915-), a Wisconsin Democrat, was a United States senator from

1957 to 1989. He won a special election to fill the seat left vacant when Senator Joseph R. McCarthy died. Proxmire served as chairman of the Senate's powerful Banking, Housing, and Urban Affairs Committee from 1975 to 1981 and from 1987 to 1989.

As a senator, Proxmire took a liberal stand on most issues. He sponsored the Consumer Credit Protection Act of 1968, often called the Truth in Lending Act. This act requires businesses to state charges for loans and installment purchases in terms of the true annual interest rate. In 1971, he led a Senate campaign to halt government funds for development of a supersonic transport airplane. He also criticized wasteful military spending.

Proxmire was born in Lake Forest, Ill. He graduated from Yale University in 1938 and received an M.B.A. degree from Harvard University in 1940. From 1941 to 1946, he served in the Army. Proxmire was an assemblyman in the Wisconsin legislature in 1951 and 1952, and he headed a Wisconsin newspaper chain from 1954 to 1957. William J. Eaton

Proxy is a substitute. Suppose you have been assigned to deliver an important report before a meeting of your club. On the day of the meeting you are too ill to attend. You therefore call upon another club member to act for you. This club member becomes your *proxy* and delivers your report to the club meeting.

The use of a proxy is limited almost entirely to business meetings. A stockholder in a corporation who is unable to attend a corporation meeting may request another stockholder to act as a substitute and vote on any issue. This must be a formal request. The person who casts the vote is known as a proxy. The paper that authorizes the substitute to vote is also called a proxy.

In political elections, voting by proxy is forbidden. But at political conventions, many delegates vote by proxy.

In law and the social sciences, an easily measured trait is sometimes said to be a proxy for a trait that is more difficult to measure. For example, in laws that prohibit the drinking of alcohol by minors, a person's age is a proxy for maturity. Jethro K. Lieberman

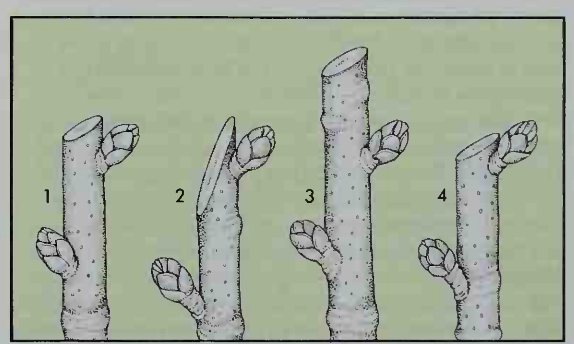
Prune is a sweet plum that has been dried. The drying gives prunes their wrinkled appearance. Plums that are especially well suited to drying have a high sugar content and are called *prune plums.* Prunes are high in iron and vitamins.

Prune plums were first grown in western Asia, near the Caucasus Mountains and the Caspian Sea. Today they are a leading crop in California, where about 160,000 short tons (145,000 metric tons) of prunes are produced yearly. The warm, dry climate of the fertile valleys provides ideal growing conditions. Prunes are also grown in the northwestern part of the United States, central Europe, and South America.

The French prune plum (Petite d'Agen) makes up 90 per cent of the prune production in California. It was brought to the United States from France in 1856 by Louis Pellier, a fruit grower. Other prune plums include the Imperial, the Sugar, and the Robe de Sergeant.

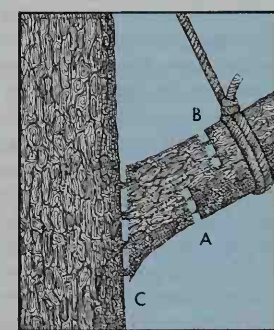
Prune plum trees usually produce a crop five to seven years after planting. The trees bloom in spring. The fruit develops in summer. In August or September, the fully developed fruit falls to the ground or is machine harvested. It is then taken to a dehydrator in lug boxes or portable bins, where it is placed for a few seconds in a hot lye solution. The dehydrator dries the plums with a forced draft of hot air. The drying lasts from 14 to 24 hours and reduces 3 pounds (1.4 kilograms) of fresh plums to about 1 pound (0.5 kilogram) of prunes.

The prunes are placed in bins, where they are *cured* for at least two weeks. Curing gives the prunes a uniform moisture content of between 18 and 20 per cent. The prunes are then graded according to size, and may be pitted. Before the prunes are packed to be sold, they are given a hot water or steam bath to pasteurize them and to bring their moisture content to between 26 and 32 per cent. James E. Pollard



See also **Plum**.

Pruning is the cutting away of plant parts, such as branches, shoots, buds, or roots. Pruning serves various functions. It helps plants recover from the shock of being moved. It controls the shape and appearance of plants. Pruning also contributes to the size, quantity, and quality of fruit.



Transplanted trees and shrubs are pruned to prevent water loss through the leaves. As much as three-fourths of the leaf-producing area often must be removed to prevent excessive water loss. However, the top of a shade tree should not be pruned, because such pruning would destroy the shape of the tree. Spruce, pine, and similar evergreens usually are not cut. They develop naturally into their characteristic shapes.

Gardeners remove weak stems from shrubs at ground level. The diseased and broken branches are also removed. Shrubs that flower early in the spring, such as lilacs, should be pruned just after they flower. Shrubs that flower in the summer, like hybrid tea roses, are pruned in the spring. Gardeners shear hedges to encourage dense and compact growth and to keep the hedges in a desired shape.

Fruit growers prune their fruit trees annually. By cut-

WORLD BOOK illustrations by Patricia J. Wynne

Principles of pruning. Figure 1 in the illustrations above shows a correctly pruned branch. The angled cut is just above the bud. In figure 2, the angle of the cut is too sharp. The cut in figure 3 is too high above the bud, and in 4 it is too close to the bud. The correct method of removing a tree limb is shown at the right. The limb is cut halfway through at A and then at B before it is cut close to the trunk at C.

J. A. Barden, Photo/Nats

Pruning often involves removing certain top branches so that lower ones can receive more sunlight. These photographs show, *left to right,* an apple tree before and after pruning. The wooden boards placed in the pruned tree force the branches to grow in the desired direction.

ting out undesirable parts, they obtain low trees with open tops. Such pruning allows light to reach all parts of the tree. It also makes spraying the trees and picking the ripe fruit easier. Well-pruned trees produce high-quality fruit. Trees pruned so that the limbs are well spaced are less likely to break when the fruit loads down their branches.

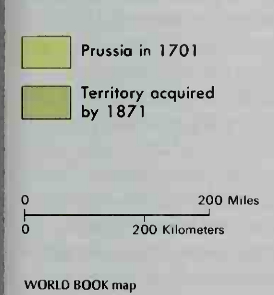
Training of a fruit tree begins when the tree is transplanted in the field from the nursery. At that time, the grower prunes the tree to a height of 36 inches (91 centimeters). This pruning stimulates the development of branches. The next year, the grower selects the strongest and best branches to remain on the tree and cuts the others off. In their early years, fruit trees require little pruning. Old trees are pruned more heavily to allow light to reach the branches and to help fruit-bearing limbs grow in desired locations. George C. Martin

Prussia was a powerful Germanic nation in north-central Europe for hundreds of years. In the 1860's and early 1870's, Prussia unified the many independent German states, creating the German Empire in 1871. The Prussian king became emperor. Prussia was the largest and most powerful state in the newly unified Germany. After World War II (1939-1945), Prussia was broken up into small districts and ceased to exist as a German state. Much of the land once called Prussia now lies in Lithuania, Poland, Russia, and eastern Germany.

Prussia was more than the name of a country, however. It also represented a military way of life. Prussian armies were among the most rigidly drilled and disciplined in the world. Their generals were from the aristocratic landowning class and owned large estates.

The land and its resources. At the height of its power in the late 1800's, Prussia occupied most of the northern two-thirds of Germany. Prussia controlled territory that extended from Belgium and the Netherlands on the west to Russia on the east. The North Sea and the Baltic Sea bordered Prussia on the north. Austria-Hungary lay to the south. Prussia's main cities were Berlin, which was the capital, and Königsberg (now Kaliningrad), which was located in East Prussia.

Prussia had a low, sandy coast, bordered by many lagoons. The coast was separated from the central plain of Prussia by a belt of lakes and tree-covered hills. The central plain contained many lakes and waterways. Highlands south of the plain contained deposits of many minerals, including coal, iron, silver, copper, nickel, and lead. The most fertile land for farming lay in the valleys of the Oder, Elbe, and Rhine rivers.



The Prussian people. The rulers of Prussia were headed by the royal family of Hohenzollern. They controlled lands originally populated by Slavs, and conquered and colonized by Germans in the Middle Ages. By the late 1500's, a small number of aristocratic landlords, called *Junkers,* had come to own most of the land in Prussia. The people who worked on the Junkers' estates were called *serfs.* Serfs rarely owned their own land. They were bound from birth to their lord's estate and were obligated to farm the lord's land. Male serfs were also forced to serve in the army.

Early history. The story of the rise of the Hohenzollern family is the story of Prussia. The Hohenzollerns were a family of German counts. In 1415, Holy Roman Emperor Sigismund made Frederick of Hohenzollern the ruler, or *margrave,* of the large district, or *mark,* of Brandenburg. In 1417, Frederick received the title elector of Brandenburg, which allowed him and his successors to take part in elections of the Holy Roman emperors. In the 1600's, the Hohenzollerns added East Prussia and Pomerania to their territory.

Prussia was greatly strengthened during the rule of the Great Elector, Frederick William, from 1640 to 1688. His son, Frederick I, was crowned the first king of Prussia in 1701. He built a strong army.

Frederick II, or **Frederick the Great,** became king of Prussia in 1740. He was an enlightened ruler who believed that the king's duty was to be "the first servant of the state." Frederick II helped shape a government based on discipline and authority, whose primary function was to support the Prussian military.

Prussia became the greatest military power in Europe during the 1800's. It began as the German district of Brandenburg and grew into the Kingdom of Prussia in 1701. Prussia reached its peak in 1871, when it became the largest state in the newly formed German Empire.

WORLD BOOK map

Using the strong army his father had organized, he seized Silesia from Austria in 1740. In the late 1700's, he expanded Prussia further by taking part of Poland.

Napoleonic period. Less skillful rulers followed Frederick II, and Napoleon easily defeated the Prussians in 1806. Reformers initiated changes hoping to restore Prussia's power. The Junkers lost their near monopoly of the land and of officer posts in the army. The serfs were freed, and a few peasants gained land. Army reformers established universal military training and invigorated the army with patriotic spirit. A Prussian army commanded by Gebhard von Blücher helped defeat Napoleon at Leipzig in 1813 and at Waterloo in 1815.

German empire. Prussia reached the peak of its power after King Wilhelm I was crowned in 1861 and chose Otto von Bismarck as prime minister. Bismarck strengthened the Prussian army and set out to unify Germany under Prussian control. In 1864, Prussia and Austria gained the Danish duchies of Schleswig and Holstein. A quarrel between Austria and Prussia in 1866 led to the Seven Weeks' War, which Prussia won. Prussia then formed the North German Confederation, unifying all of Germany north of the Main River. In 1870, Bismarck maneuvered France into war. Germany's success in the war enabled Bismarck to persuade Germany's southern states to join with the North German Confederation in forming the German Empire. The empire was established in 1871 with King Wilhelm I as its first *kaiser* (emperor).

Decline of Prussia. Prussian militarism was one cause of World War I (1914-1918), a war that Germany lost. In the peace settlement, Poland gained a strip of land called the *Polish Corridor.* This land separated East Prussia from the rest of Germany. World War II began after German dictator Adolf Hitler invaded Poland to reclaim the land lost in World War I. Prussian generals, some of them Junkers, commanded many of Hitler's armies. But some Prussian Junkers opposed Hitler and were executed after they plotted to assassinate him. The war brought heavy destruction to Prussia.

When the war ended, the Allies gave the northern half of East Prussia to the Soviet Union. The rest of Prussia east of the Oder and Neisse rivers, along with the city of Stettin (now Szczecin), became part of Poland. In 1947, the Allied Control Council legally abolished the state of Prussia. Robert M. Berdahl

Prussian blue is a dark blue solid substance with a coppery luster. It was formerly used in the manufacture of laundry bluing, paint, and blue ink. Aniline products, however, are replacing Prussian blue for these purposes (see **Aniline**). The chemical is prepared commercially by mixing ferrous sulfate and sodium ferrocyanide, and then adding sodium chlorate. Prussian blue does not crystallize or dissolve in water. But alkalis will decompose it (see **Alkali**). Its chemical formula is $Fe_4[Fe(CN)_6]_3$. A color used in oil painting is also called Prussian blue. Howard L. Needles

Prussic acid, also known as *hydrocyanic acid,* HY *droh sy AN ihk,* is called *prussic acid* because it was first obtained from Prussian blue (see **Prussian blue**). The pure acid is a clear liquid. It has a low boiling point and evaporates quickly at room temperature. The acid has a faint odor of bitter almonds. It interferes with the body's ability to use oxygen and is one of the most poisonous substances known. Hydrocyanic acid gas has been used to execute condemned criminals. The gas is created when lumps of sodium or potassium cyanide are dropped into sulfuric acid. Hydrocyanic acid is also used to control the scale insect on orange trees. The

acid's chemical formula is HCN. The salts of this acid have many industrial uses. Marianna A. Busch

See also Cyanide.

Przewalski's horse, *puhr zheh VAHL skihz,* also called *Przhevalski's horse,* is the only true wild horse that exists today. Other "wild" horses, such as those found in the western United States, are actually descendants of runaway domestic horses. The Russian explorer Nikolai M. Przewalski found the skin and skull of one of these wild horses in central Asia in 1881. About 20 years later, animal collectors caught 32 colts.

Przewalski's horse is related to the domestic horse, but it resembles a donkey. It has a grayish-brown coat, a brown mane, and a black streak along its back. There are faint bars on its upper legs, and its lower legs are black. Przewalski's horse stands about 53 inches (135 centimeters) tall at the shoulder. It is an endangered species. More than 1,500 of these horses live in captivity. In 1995, scientists began a program to release captive-bred Przewalski's horses into the wild in an effort to reestablish them in their natural habitat. Steven D. Price

See also Horse (Wild horses; picture); Tarpan.

Scientific classification. Przewalski's horse belongs to the family Equidae. It is *Equus przewalskii.*

Psalms, *sahmz* or *sahlmz,* **Book of,** is a collection of 150 poems or songs in the Old Testament, or Hebrew Bible. The book is sometimes called the Psalter. The Psalms were probably part of the religious ceremonies of the ancient Israelites. Even today, the Psalms are used in both Jewish and Christian worship services.

Much of the Old Testament consists of the history of Israel or God's commands to His people. The Psalms are a special part of the Old Testament because they tell about people's personal responses to God. The Psalms reveal the individual's feelings when faced with both the joys and the sorrows of everyday life. The Psalms contain hymns praising and thanking God and prayers to God in times of trouble. Perhaps the best known Psalm is number 23, which begins, "The Lord is my shepherd; I shall not want."

The Book of Psalms is associated with the Israelite leader King David. According to tradition, David wrote 73 of the Psalms. However, many modern scholars doubt that he wrote all of them. Other musicians may have written the Psalms to honor him. King David was a famous musician, and the Psalms were probably an important part of the musical life of ancient Israel.

Many of the Psalms were probably written in King David's time, about 1000 B.C. Some of the Psalms may have been based on ancient Near Eastern songs and thus could be even older. Many Biblical prophets were influenced by the Psalms. Therefore, much of the book had probably been established by the age of prophecy in ancient Israel, which began in the 700's B.C. Some Psalms may reflect historical events that took place as late as the 500's B.C. Carol L. Meyers

Pseudonym, *SOO duh nihm,* is a fictitious name taken by authors and other people who wish to conceal their true identities or simply to be known by another name. One famous author's pseudonym is Mark Twain, the name adopted by the American humorist Samuel Langhorne Clemens. The "stage names" assumed by actors and actresses are also kinds of pseudonyms. See also Name (Other names). Marcus Klein

Psi particle, *sy,* also called a *J particle,* is a type of subatomic particle. A psi particle consists of a *quark* and an *antiquark.* A quark is an elementary particle that combines with other quarks to form such familiar particles as protons and neutrons. An antiquark has the same properties as a quark but carries an opposite electric charge. In a psi particle, the quark is a *charm quark,* and the antiquark is an *anticharm quark.* See Quark.

The structure of a psi particle is similar to that of a hydrogen atom. Both a hydrogen atom and a psi particle consist of two particles bound together. However, the components of a hydrogen atom—a proton and an electron—are bound together by electromagnetism. The quark and antiquark of a psi particle, on the other hand, are held together by the *strong nuclear force,* also called the strong interaction (see Force [The strong force]). Just like a hydrogen atom, a psi particle carries no electric charge.

The psi particle was discovered in 1974 by two groups of American physicists working independently at the Stanford Linear Accelerator Center and Brookhaven National Laboratory. The discovery of the psi particle and the study of its properties provided strong evidence for the existence of the quark. Stanley G. Wojcicki

Psittacosis, *SIHT uh KOH sihs,* is a contagious disease that is carried by some kinds of birds. The disease is also called *parrot fever* or *ornithosis.* Psittacosis occurs mostly in members of the parrot family, but is also found in pigeons and some poultry. Human beings can contract this disease by handling sick birds or infectious articles.

Psittacosis is caused by a type of bacteria called a rickettsia. Symptoms include nausea, diarrhea, chills, and high fever. Antibiotics will cure some cases, but serious infections can cause pneumonia or death. Because of this disease, the government forbids the importation of parrots into the United States without rigid inspection.

John W. Fitzpatrick

Psoriasis, *suh RY uh sihs,* is a skin disease marked by red patches of dry, scaly skin. Mild cases of psoriasis affect only small areas of the skin, while more severe attacks may cover the entire body. In skin afflicted with psoriasis, cells multiply at an abnormally high speed. These cells do not *exfoliate* (peel away) properly. Also, blood vessels beneath the skin enlarge and release chemicals that cause swelling.

Psoriasis is not contagious. However, infection, medicine, or an injury to the skin may cause an attack of psoriasis. Emotional factors, such as tension, may also influence outbreaks. Many people afflicted with psoriasis have a history of psoriasis outbreaks in their family. Doctors believe that psoriasis may be a *genetic disease,* a disease that is inherited from a parent. Many people with psoriasis also suffer from a form of arthritis, but the skin patches themselves do not cause arthritis.

Although psoriasis cannot be cured, *dermatologists* (skin doctors) can treat its symptoms. For mild cases, dermatologists often apply medicine directly to the skin. Cortisones, coal tar, and a drug called anthralin reduce swelling, slow cell growth, and relieve itching. Doctors can also apply chemicals, such as salicylic acid and urea, to force the excess skin to peel away. Vitamin D solutions can slow the rate at which skin cells multiply. In more severe cases, physicians shine ultraviolet light on

the skin to slow the growth of skin cells. As a last resort, doctors may prescribe oral medicine for psoriasis. With proper treatment, psoriasis can be cleared up for long periods. Alan K. Silverman

Psyche, *SY kee,* was a princess in ancient mythology. She was so beautiful that people turned to worshiping her instead of Venus, goddess of love. Venus became angry and sent her son Cupid (Love) to punish her. However, Cupid fell in love with Psyche and carried her off to his fairyland palace of gold and gems. Cupid visited Psyche only at night and told her that, if she ever saw him in the light, he must leave her forever. But Psyche, urged by her wicked sisters, one night lighted a lamp to see Cupid as he slept. He awoke and left her.

In her grief, Psyche searched for Cupid, finally arriving at the palace where Venus was living. The goddess made Psyche her slave and gave her four nearly impossible tasks. Psyche performed the first three, but in the fourth, a visit to the queen of the underworld, Psyche failed and became trapped in the underworld. Cupid, however, rescued her. With the help of Jupiter, king of the gods, Cupid won Venus's forgiveness and made Psyche a goddess and his wife. See **Cupid.**

The story of Cupid and Psyche has been interpreted symbolically. According to this interpretation, Psyche (which means *soul* in Greek) represents the human soul's encounter with love and passion (Cupid) and its struggle to achieve immortality. Jon D. Mikalson

Psychedelic drug. See **Hallucinogenic drug.**

Psychiatry, *sy KY uh tree,* is the branch of medicine concerned with the treatment and prevention of mental illness. A psychiatrist is a physician who, after earning an M.D., takes at least four years of training in the treatment of mentally ill patients.

Many techniques are used in treating mentally ill patients. A psychiatrist might discuss problems with one patient; prescribe drugs for another; and combine discussions, drugs, and other therapy for a third.

Some psychiatric therapy takes place in a psychiatrist's office or in a clinic. But severe cases require hospital care. Many hospitals and clinics employ psychiatric nurses, psychiatric social workers, and clinical psychologists. These specialists have had special training to help patients solve their problems.

Psychiatric disorders

Mental disorders are characterized by a variety of symptoms, such as abnormal moods or behavior, excessive anxiety, and hallucinations. These symptoms often upset the person who experiences them and may interfere with the person's ability to lead a normal life. The causes of most mental disorders are unknown. Some may arise from emotional conflicts or psychological stress. Others may result from learned behavior patterns or are caused by biological defects in the brain. Many mental disorders are believed to result from a combination of emotional, social, and biological factors.

Ways of defining and classifying mental disorders have changed over time. Older classification systems made a distinction between *psychoses* and *neuroses.* Psychoses are severe mental disorders in which a person loses touch with reality and experiences such symptoms as delusions and hallucinations (see **Psychosis**). Neuroses are milder disorders marked by excessive anxiety (see **Neurosis**). Other kinds of mental disorders include *dementias* and *personality disorders.* Dementias are abnormalities in thinking or behavior caused by brain injury or brain deterioration. Personality disorders involve a tendency to act in socially unacceptable or self-defeating ways. Most psychiatrists in the United States use a classification system published by the American Psychiatric Association in 1994. This system includes more than 100 types of mental disorders defined by their symptoms.

Treatment

Psychiatrists use a number of treatments for mental disorders. The two main types of treatments are (1) somatic therapy and (2) psychotherapy.

Somatic therapy usually involves the use of medications. One commonly used group of medications are *neuroleptic* drugs, sometimes called *antipsychotics.* These drugs are used mainly to treat psychosis. *Antidepressants* are a group of drugs used to control abnormalities of mood. *Anxiolytics* reduce anxiety and are used chiefly to treat conditions characterized by excessive anxiety, including phobias and panic disorder. *Lithium carbonate* is a drug used to treat *bipolar disorder,* also called *manic-depressive disorder.* A person with this disorder experiences alternating periods of sadness and joy.

A type of somatic therapy called *electroconvulsive therapy* is sometimes used to treat severe depression. In this type of therapy, a mild electric current is passed through the patient's brain after the patient has been given a drug that causes sleep. See **Mental illness** (Electroconvulsive therapy [ECT]).

Psychotherapy is any form of treatment by psychological means. There are many types of psychotherapy. Most psychotherapy is based on discussions between the patient and the psychiatrist. The doctor works to build the patient's confidence and to help the patient develop a more contented outlook toward life. Commonly, the patient and doctor meet for a psychotherapy session once or twice a week for several months. But sessions may occur more frequently or less frequently.

Sometimes groups of 4 to 12 patients participate in *group therapy.* By meeting as a group with the psychiatrist, the patients help each other understand themselves.

When working with a child, the psychiatrist may use *play therapy.* The child, instead of talking about his or her problems, acts them out with toys and games.

Two widely used forms of psychotherapy are *psychoanalysis* and *behavior therapy.* Psychoanalysis focuses on unconscious thoughts and feelings. According to psychoanalytic theory, the causes of many mental illnesses lie buried in the unconscious. The patient meets with the psychiatrist and talks about whatever comes to mind. The physician helps the patient understand his or her problems by uncovering the causes. Psychoanalysis may last for a number of years. See **Psychoanalysis.**

Behavior therapy aims to help patients change their behavior rather than help them understand why they act the way they do. Psychiatrists use *positive* and *negative reinforcement* to encourage patients to act in a healthier way. Using positive reinforcement, the psychiatrist praises or rewards the patient for "good" behavior. This

technique is considered more effective than negative reinforcement, which includes scolding the patient for "bad" behavior. Nancy C. Andreasen

Psychical research, *SY kuh kuhl,* is the original name of a field of study that is now known as *parapsychology.* It involves the investigation and study of so-called *psychical* (mental) phenomena that are outside the field of normal psychology and the ordinary laws of behavior. Historically, psychical research focused on *spiritualism* (communication with the dead), the existence of ghosts, and fortunetelling. Modern interest is directed at *extrasensory perception (ESP)* and related phenomena. ESP is an awareness of something, such as another person's thoughts, without the use of the senses of hearing, sight, smell, taste, or touch.

Throughout history, there have been many reports and claims of psychical phenomena. Some can be neither verified nor disproved. Psychical research can provide a basis for an assumption that psychical phenomena exist, or it can expose false or fraudulent claims. But most scientists believe that the existence of such phenomena has not been proved. James E. Alcock

Psychoanalysis, *sy koh uh NAL uh sihs,* is a method of treating mental illness founded by the Austrian physician Sigmund Freud. Freud developed this treatment during the late 1800's and early 1900's. Other psychiatrists developed variations of his technique. The term *psychoanalysis* also refers to the theories on which such treatment is based.

According to Freud, a number of mental disorders could be cured by uncovering a patient's unconscious wishes and fears. He believed that behavior is influenced by instincts, fears, and unconscious mental processes not controlled by rational thought. He claimed that early childhood bodily experiences, including sexual ones, shape an individual's behavior in later life.

Psychoanalysts believe that unpleasant experiences, especially during childhood, may become buried in the unconscious mind and, together with inborn tendencies, may cause mental illness. Psychoanalytic treatment tries to bring these experiences out of a patient's unconscious mind and into the conscious mind.

Psychoanalytic treatment generally lasts for two to five years with sessions three to five times a week. The patient is instructed to reveal all thoughts as they occur. This is called *free association.* The patient and the analyst attempt to understand the psychological meaning of the ideas, fantasies, dreams, and behaviors that are expressed. During the course of the treatment, patients often transfer strong feelings they have for other people to the therapist. This process is called *transference.* Transference reveals certain attitudes acquired by patients in early life that have continued to interfere with their relationships with other people. By interpreting this transference, the therapist attempts to help patients achieve greater maturity and freedom in their relationships. Today, variations of psychoanalysis that involve much briefer and less intense treatments are much more commonly practiced.

Psychoanalytic theory. Freud taught that people do not say or do anything accidentally. Unconscious mental activity causes such "accidents" as slips of the tongue—for example, calling a person by the wrong name without realizing it—or forgetting an appointment. According to Freud, the mind experiences more unconscious than conscious activity.

Freud divided the mind into three parts: (1) the *id,* (2) the *ego,* and (3) the *superego.* Babies are born with an id, a group of instincts within the unconscious. As children grow, they develop an ego and a superego. The ego governs such areas as memory, voluntary movement, and decision making. The superego enables the mind to tell right from wrong. Severe conflicts between two of the parts may cause emotional problems. Difficulties might arise, for example, if the id produces strong desires to do things, but the superego insists that such desires are wrong.

Freud believed that children grow through a series of five overlapping stages of what he called *psychosexual development.* These stages are (1) the *oral phase,* (2) the *anal phase,* (3) the *phallic stage,* (4) *latency,* and (5) *adolescence.* During the oral phase, infants find pleasure in sucking. During the anal phase, which lasts to about age 4, children enjoy controlling the discharge of body wastes. Then, in the phallic stage, they become increasingly aware of their sex organs. They also develop an *Oedipus complex,* a strong attraction to the parent of the opposite sex. While in elementary school, children move into the less emotional latency period. Adolescence involves a struggle between childish feelings of dependency and adult longings for independence.

Emotional problems during any of the five stages, according to Freud, can cause characteristics of that stage to last into adulthood. A disturbed boy, for example, might remain unconsciously in love with his mother and jealous of his father even as an adult. Allen Frances

Psychological warfare, *SY kuh LAHJ uh kuhl,* uses propaganda to reach certain goals. It can be used before a war to deter fighting, or during a war to win it. A nation uses psychological warfare to convince its poten-

tial enemies that they cannot possibly win, and that they should not start to fight. During a war, it uses psychological warfare to convince enemy troops that their cause is unjust and hopeless. Its goal is to destroy the enemy's will to fight. Joel Slackman

Psychology is the scientific study of mental processes and behavior. Psychologists observe and record how people and other animals relate to one another and to the environment. They look for patterns that will help them understand and predict behavior, and they use scientific methods to test their ideas. Through such studies, psychologists have learned much that can help people fulfill their potential as human beings and increase understanding between individuals, groups, nations, and cultures.

Psychology is a broad field that explores a variety of questions about thoughts, feelings, and actions. Psychologists ask such questions as: "How do we see, hear, smell, taste, and feel? What enables us to learn, think, and remember, and why do we forget? What abilities are we born with, and which must we learn? How do our abilities change as we grow older? How much does the mind affect the body, and how does the body affect the mind? For example, can we change our heart rate or temperature just by thinking about doing so? What can our dreams tell us about our needs, wishes, and desires? Why do we like the people we like? Why are some people bashful and others not shy at all? What causes violence? What is mental illness, and how can it be treated?"

The research findings of psychologists have increased our understanding of why people behave as they do. For example, psychologists have discovered much about how personality develops and how to promote healthy development. They have some knowledge of how to help people change bad habits and how to help students learn. They understand some of the conditions that can make workers more productive.

A great deal remains for psychologists to discover. Nevertheless, insights provided by psychology can help people function better as individuals, friends, family members, and workers.

Psychology and other sciences

Psychology is closely related to the natural science of biology. Like many biologists, psychologists study the abilities, needs, and activities of human beings and other animals. But psychologists focus on the workings of the nervous system, especially the brain.

Psychology is also related to the social sciences of anthropology and sociology, which deal with people in society. Like anthropologists and sociologists, psychologists investigate the attitudes and relationships of human beings in social settings. These three academic disciplines often study the same kinds of problems from different perspectives. However, psychologists concentrate on individual behavior. They are especially interested in the beliefs and feelings that influence a person's actions.

In addition, psychology is similar to a medical field called *psychiatry*. Most psychologists have an M.A. or Ph.D. degree and may or may not specialize in the treatment of psychological disorders. Psychiatrists, on the other hand, have an M.D. degree and devote themselves to treating psychological disorders.

Methods of psychological research

In their research, psychologists use much the same approach as other scientists do. They develop theories, also called *hypotheses,* which are possible explanations for what they have observed. They then use scientific methods to test their hypotheses. The chief techniques used in psychological research include (1) naturalistic observation, (2) systematic assessment, and (3) experimentation.

Naturalistic observation involves watching the behavior of human beings and other animals in their natural environment. For example, a researcher might study the activities of chimpanzees in the wild. The psychologist looks for cause-and-effect relationships between events and for broad patterns of behavior.

Group therapy enables psychologists to counsel several individuals at one time. In such a group, people who face similar challenges meet to share experiences and learn from one another. The group setting encourages members to provide social and emotional support for the other members.

Psychologists conducting such studies try to observe a group large enough and typical enough to accurately reflect the total population. Such a group is called a *representative sample.* Observers also attempt to keep their personal views from influencing the study. In addition, psychologists try to prevent their presence from affecting the behavior being observed. A careful scientist hides from sight or remains on the scene long enough to become a familiar part of the environment.

Naturalistic observation is a valuable source of information to psychologists. The research itself has less effect on the subjects' behavior than a controlled experiment does. But observation alone seldom proves a cause-and-effect relationship between two or more events. As a result, psychologists use naturalistic observation chiefly as an exploratory technique to gain insights and ideas for later testing.

Systematic assessment is the general name for a variety of organized (systematic) methods used to examine (assess) people's thoughts, feelings, and personality traits. The chief types of systematic assessment include case histories, surveys, and standardized tests.

A *case history* is a collection of detailed information about an individual's past and present life. Nearly all clinical psychologists gather case histories of their patients to help them understand and treat the patients' problems. A psychologist who notices similar experiences or patterns of thought in several case histories may gain insight into the causes of certain emotional disorders.

A *survey,* sometimes in the form of a *public opinion poll,* is a study that measures people's attitudes and activities by asking the people themselves. Surveys provide information on attitudes and behaviors, such as political views or consumer buying habits, and many other topics. A psychologist conducting a survey prepares carefully worded questions. The researcher may interview participants personally or mail questionnaires to them. If the psychologist wishes to form general conclusions, the survey must collect responses from a representative sample of individuals.

A *standardized test* is an examination for which average levels of performance have been established and which has shown consistent results. In addition, uniform methods of administering and scoring the test must have been developed. Psychologists use standardized tests to help measure abilities, aptitudes, interests, and personality traits. For example, most students who plan to attend college take a standardized test called a *college entrance examination* during their junior or senior year in high school. This test measures some of the abilities thought to contribute to a student's success in college.

Still other tests, called *projective tests,* yield clues to a person's inner feelings. In a Rorschach test, for example, the subject describes what he or she sees in a series of inkblots. In the Thematic Apperception Test, the subject invents a story about the characters in each of a series of pictures. Psychologists can interpret responses on these tests as expressions of an individual's personality.

Case histories, surveys, and standardized tests enable psychologists to gather much information that they could not detect by naturalistic observation. However, the accuracy of the information gathered from such sources depends on well-designed studies and on truthful, complete responses from the individuals who participate.

Major fields of psychology

Abnormal psychology deals with psychological disorders and disturbed individuals. For example, researchers might investigate the causes of violent or self-destructive behavior or the effectiveness of procedures used in treating an emotional disturbance, such as depression.

Biological psychology examines the relationship between behavior and body structures or functions, particularly the workings of the nervous system. Biological psychologists explore the functions of the brain, how hormones affect behavior, and the physical processes involved in emotions, sensory experiences, and *cognition* (the process by which people acquire knowledge, solve problems, and make plans).

Clinical psychology uses the understandings derived from developmental and abnormal psychology to diagnose and treat psychological disorders and adjustment problems. Some clinical psychologists work to develop programs for the prevention of emotional illness or conduct basic research on how individuals can better cope with the problems of daily life.

Cognitive psychology explores the way people acquire, store, and retrieve information. Psychologists in this field might try to understand why people forget, or they might study the mental steps people use to solve problems.

Counseling psychology helps people adjust to changes in their lives or lifestyles. Counseling psychologists may help people make career decisions, deal with personal or relationship problems, or stop destructive behaviors, such as smoking or chronic overeating.

Developmental psychology studies the physical, cognitive, and social changes that occur across the life span of human beings. Many developmental psychologists specialize in the study of children or adolescents. Gerontology, a related field, focuses on physical, psychological, and social experiences and changes among older adults.

Educational psychology aims to improve teaching methods and materials, to solve learning problems, and to measure learning ability and educational progress. Researchers in this field may devise achievement tests, develop and evaluate teaching methods, or investigate how children learn at different ages.

Evolutionary psychology examines how genes respond to natural selection to produce particular traits or behaviors. Researchers in this field might try to explain differences in sexual or social behavior between men and women in terms of natural selection experienced by prehistoric human beings.

Industrial psychology is concerned with people at work. Industrial psychologists investigate such matters as how to make jobs more rewarding or how to improve workers' performance. They also study personnel selection, leadership, and management. Organizational psychology is a related field.

Perception, in psychology, is the study of how an organism becomes aware of objects, events, and relationships in the outside world through its senses. Psychologists in the field of perception analyze such topics as vision, hearing, taste, smell, touch, and movement.

Personality refers to the characteristics that make individuals different from one another and account for the way they behave. Personality psychologists investigate how an individual's personality develops, the chief personality types, and the measurement of personality traits.

Social psychology studies the social behavior of individuals and groups, with special emphasis on how behavior is affected by the presence or influence of other people. Social psychologists concentrate on such processes as communication, political behavior, formation of attitudes, and development of relationships.

Experimentation helps a psychologist discover or confirm cause-and-effect relationships in behavior. In a typical experiment, the researcher divides subjects at random into two groups. One group is called the *experimental group,* and the other is called the *control group.* For the experimental group, the researcher changes conditions that will likely affect the subjects' behavior and holds all other factors constant. The experimenter does nothing to the control group. If the experimental group behaves differently from the control group, the changed conditions probably caused the difference in behavior.

Other experiments involve repeated testing of the same subjects under different conditions. For example, a study might test how alcohol affects people's driving. Each subject would take a driving test on a laboratory simulator while sober and then repeat the test after drinking a prescribed amount of alcohol. Any difference in performance would probably be due to the alcohol consumed.

The experimental method enables scientists to test a theory under controlled conditions. But many psychologists hesitate to form conclusions based only on laboratory investigations. In many cases, people's behavior changes simply because they know they are part of an experiment.

History

Beginnings. Since ancient times, philosophers and people in general have wondered why human beings and other animals behave as they do. The origins of psychology are often traced to the ancient Greek philosopher Aristotle, who was chiefly interested in what the human mind could accomplish. Aristotle believed that the mind or soul, which the Greeks called the *psyche,* was separate from the body. He thought the psyche enabled people to reason and was the source of the highest human virtues. The word *psychology* comes from the Greek words *psyche* (mind or soul) and *logia* (study).

During the Middle Ages, scholars studied behavior chiefly from a religious rather than a scientific viewpoint.

Cognitive psychologists may study the mental abilities of animals to learn about the development of the human mind. Here, a chimpanzee recognizes its own reflection in a mirror. This may indicate that chimpanzees are self-aware, much like people.

However, several philosophers of the 1600's and 1700's made contributions to the development of psychology. René Descartes, a French philosopher, described the body and mind as separate structures that strongly influenced each other. He suggested that the interaction between body and mind took place in the pineal gland, a tiny organ in the brain.

Descartes also believed that people were born with the ability to think and reason. This doctrine, called *nativism,* was rejected in the late 1600's and early 1700's by a group of philosophers called *empiricists.* These thinkers, including Thomas Hobbes and John Locke of England, David Hume of Scotland, and George Berkeley of Ireland, believed the mind is empty at birth. They thought that knowledge of the outside world comes only through the senses, and that ideas result from people's experiences in life.

Psychology becomes a science. In the mid-1800's, two German scientists—the physiologist Johannes P. Müller and the physicist and physiologist Hermann L. F. von Helmholtz—began the first systematic studies of sensation and perception. Their work showed that the physical processes underlying mental activity could be studied scientifically.

But psychology did not develop into a science based on careful observation and experimentation until the late 1800's. The American philosopher William James founded the first psychology laboratory in the United States and wrote the first psychology textbook, *Principles of Psychology* (1890). A similar laboratory was established in Germany by Wilhelm Wundt. Wundt, a philosopher trained in medicine and physiology, also edited the first journal of experimental psychology. The work of James and Wundt marked the beginning of psychology as a distinct field that was separate from philosophy.

From the late 1800's until the 1930's, psychologists were divided about what they should study and how they should study it. Four major schools developed. These schools were (1) structuralism, (2) behaviorism, (3) Gestalt psychology, and (4) psychoanalysis.

Structuralism grew out of the work of James, Wundt, and their associates. These psychologists believed the chief purpose of psychology was to describe, analyze, and explain conscious experience, particularly feelings and sensations. The structuralists attempted to give a scientific analysis of conscious experience by breaking it down into its specific components or structures. For example, they identified four basic skin sensations: warmth, cold, pain, and pressure. They analyzed the sensation of wetness as the combined experience of cold and smoothness.

The structuralists primarily used a method of research called *introspection.* In this technique, subjects were trained to observe and report as accurately as they could their mental processes, feelings, and experiences.

Behaviorism was introduced in 1913 by John B. Watson, an American psychologist. Watson and his followers believed that observable behavior, not inner experience, was the only reliable source of information. This concentration on observable events was a reaction against the structuralists' emphasis on introspection. The behaviorists also stressed the importance of the environment in shaping an individual's behavior. They

chiefly looked for connections between observable behavior and stimuli from the environment.

The behaviorist movement was greatly influenced by the work of the Russian physiologist Ivan P. Pavlov. In a famous study, Pavlov rang a bell each time he gave a dog some food. The dog's mouth watered when the animal smelled the food. After Pavlov repeated the procedure many times, the dog's saliva began to flow whenever the animal heard the bell, even if no food appeared. This experiment demonstrated that a response—such as the flow of saliva—can become associated with a stimulus other than the one that first produced it—in this case, the sound of a bell instead of the smell of food. The learning process by which a response becomes associated with a new stimulus is called *conditioning.*

Watson and the other behaviorists realized that human behavior could also be changed by conditioning. In fact, Watson believed he could produce almost any response by controlling the rewards and punishments in an individual's environment.

During the mid-1900's, the American psychologist B. F. Skinner gained much attention for behaviorist ideas. In his book *Walden Two* (1948), Skinner describes how the principles of conditioning might be applied to create an ideal planned society.

Gestalt psychology, like behaviorism, developed as a reaction against structuralism. Gestalt psychologists believed that human beings and other animals perceive the external world as an organized pattern, not as individual sensations. For example, a motion picture consists of thousands of individual still pictures, but we see what looks like smooth, continuous movement. The German word *Gestalt* (pronounced *GUH SHTAHLT*) means *pattern, form,* or *shape.* Unlike the behaviorists, the Gestaltists believed that behavior should be studied as an organized pattern rather than as separate incidents of stimulus and response. The familiar saying "The whole is greater than the sum of its parts" expresses an important principle of the Gestalt movement.

Gestalt psychology was founded about 1912 by Max Wertheimer, a German psychologist. During the 1930's, Wertheimer and two colleagues brought the Gestalt movement to the United States. For more information, see Gestalt psychology.

Psychoanalysis was founded during the late 1800's and early 1900's by the Austrian physician Sigmund Freud. Psychoanalysis was based on the theory that behavior is determined by powerful inner forces, most of which are buried in the unconscious mind. According to Freud and other psychoanalysts, people *repress* (force out of conscious awareness) any desires or needs that are unacceptable to themselves or to society. The repressed feelings can cause personality disturbances, self-destructive behavior, or even physical symptoms.

Freud developed several techniques to bring repressed feelings to the level of conscious awareness. In a method called *free association,* the patient relaxes and talks about anything that comes to mind while the therapist listens for clues to the person's inner feelings. Psychoanalysts also try to interpret dreams, which they regard as a reflection of unconscious drives and conflicts. The goal of psychoanalysis is to help the patient understand and accept repressed feelings and find ways to deal with them.

Modern psychology has incorporated many teachings of the earlier schools. For example, though many psychologists disagree with certain of Freud's ideas, most accept his concept that the unconscious plays a major role in shaping behavior. Similarly, most psychologists agree with the behaviorists that environment influences behavior and that they should study chiefly people's observable actions. However, many psychologists object to pure behaviorism. They believe that it pays too little attention to biological and cognitive processes.

A school called *humanistic psychology* developed as an alternative to behaviorism and psychoanalysis. Humanistic psychologists believe individuals are controlled by their own values and choices and not entirely by the environment, as behaviorists think, or by unconscious drives, as psychoanalysts believe. The goal of humanistic psychology is to help people function effectively and fulfill their own unique potential. The supporters of this approach included the American psychologists Abraham H. Maslow and Carl R. Rogers.

A group of psychologists known as the *cognitive school* believe there is more to human nature than a series of stimulus-response connections. These psychologists concentrate on such mental processes as thinking, reasoning, and self-awareness. They investigate how a person gathers information about the world, processes the information, and plans responses.

Other psychologists are interested in the biological processes related to behavior and *cognition* (the process by which people acquire knowledge, solve problems, and make plans). *Neuroscientists* study how processes in the brain and nervous system create individual experiences associated with thoughts, emotions, and senses. *Behavioral geneticists* look for links between genes and behavior or personality.

The *sociocultural perspective* recognizes the role of the social and cultural environment in cognition and behavior. Psychologists working from this perspective view even themselves as subject to the cultural and historical context in which they live.

Many psychologists do not associate themselves with a particular school or theory. Instead, they select and use what seems best from a wide variety of sources. This approach is called *eclecticism.*

Careers in psychology

Most individuals who become psychologists begin by earning a bachelor's degree in psychology at a college or university. Some jobs in psychology require only a bachelor's or master's degree. But, for the broadest range of career opportunities, a psychologist needs a doctoral degree. Most individuals who plan to become clinical psychologists also serve at least a year as an *intern* at a psychological clinic. Psychology interns treat patients, but they work under the supervision of experienced therapists.

Many psychologists work for educational institutions, including colleges, universities, and public school systems. Most psychologists at such institutions combine several interests by teaching, conducting research, and serving as counselors or therapists. Many other psychologists hold jobs in hospitals, clinics, mental health centers, government agencies, research organizations, con-

sulting firms, or business companies. Still others are self-employed.

In the United States, a person who plans to have a private practice as a psychologist must be licensed by the state. Most states require that such a person have a doctoral degree. The chief professional organizations for psychologists in the United States are the American Psychological Association (APA) and the American Psychological Society (APS). Deborah South Richardson

Psychopathology. See **Abnormal psychology.**

Psychosis, *sy KOH sihs,* is a term used to describe a severe mental illness. Psychoses are characterized by a variety of symptoms that most people consider abnormal. These include *hallucinations,* such as hearing voices when no one is around, and *delusions,* such as the notion that one is being persecuted or conspired against (see **Hallucination; Delusion**).

Some psychoses have obvious physical causes. For example, the brain may be diseased as the result of an infection such as *general paresis,* which is caused by syphilis. Or, a physical illness of another part of the body may affect the brain, as in delirium due to pneumonia. These are called *organic psychoses.* In *toxic psychoses,* a harmful or poisonous substance (toxin) affects the brain. An example of this is a psychosis caused by lead poisoning.

Other psychoses have no obvious physical cause. The most common psychosis is *schizophrenia* (see **Schizophrenia**). Nancy C. Andreasen

See also **Mental illness.**

Psychosomatic medicine, *sy koh soh MAT ihk,* is the use of the methods and principles of psychology in the treatment of physical ailments. The term is taken from the Greek words *psyche,* which means *mind,* and *soma,* which refers to the body.

Doctors have long known that emotional disturbances affect a person's body. For example, when a person is afraid or angry, epinephrine flows into the blood, increasing the action of the heart. Certain mental conflicts may make a person more susceptible to disease, or cause what appears to be a disease.

Bodily disorders that historically have been thought to be related to emotional disturbances include asthma, *peptic ulcers* (stomach or duodenal ulcers), *rheumatoid arthritis* (inflammation and stiffness of the joints), *neurodermatitis* (chronic skin disorders), and *hypertension* (high blood pressure). However, this concept is losing popularity among doctors.

Psychosomatic medicine usually is not considered a special field of medicine. Most medical doctors have had some training in psychology and psychiatry. They often use psychological methods along with other methods of treatment. Some patients need help from doctors who specialize in psychiatry. Paula J. Clayton

Psychotherapy, *sy koh THEHR uh pee,* is any treatment of mental or emotional disorders by psychological means. Most psychotherapy is based on discussions between a therapist and one or more patients.

There are three principal types of psychotherapists: (1) psychiatrists, (2) psychologists, and (3) psychiatric social workers. Psychiatrists have an M.D. degree and advanced training in the diagnosis and treatment of psychological disorders. Psychiatrists are the only psychotherapists permitted to prescribe tranquilizers and other drugs as part of the treatment. Most psychologists have a Ph.D. degree and practical training in psychology. Most psychiatric social workers have a master's degree and training in techniques of psychotherapy. In addition, psychiatric nurses may play a role in psychotherapy.

Psychotherapy includes a wide range of techniques based on different ideas and theories about the causes of psychological disorders. Some psychotherapists use one form of therapy for all their patients. However, many therapists vary their techniques to suit the nature of the patient's problems. Scientists disagree over how much psychotherapy can accomplish for troubled individuals, but most agree that it can be helpful. There is no evidence that one form of therapy is more effective than any other. Much depends on the experience, skill, and warmth of the therapist, and on the relationship he or she establishes with each patient.

Most techniques of psychotherapy may be classified according to three general approaches: (1) analytic, (2) behavioral, and (3) humanistic. There are other forms of psychotherapy that cannot be classified in any of these main categories. A psychotherapist who uses any approach may also use a technique called *group therapy.*

Analytic psychotherapy. The best-known type of analytic psychotherapy is *psychoanalysis,* a method of treatment developed by the Austrian physician Sigmund Freud. Psychoanalysis is based on the theory that psychological disorders are caused by conflict between conscious and unconscious influences. For example, an individual's sex drives may conflict with his or her moral standards. According to psychoanalysts, people develop methods called *defense mechanisms* to deal with conflicts that they cannot resolve. Perhaps the most common defense mechanism is *repression,* the forcing of unpleasant feelings or painful memories from the conscious part of the mind into the unconscious part. The goal of psychoanalysis is to bring repressed conflicts to conscious awareness. The patient may then be able to understand the conflicts and deal with them.

Psychoanalysts use several techniques to penetrate a patient's defense mechanisms. For example, Freud developed a method called *free association,* in which the patient relaxes and talks about anything that comes to mind. The therapist listens for clues to the individual's unconscious motives. Psychoanalysts also try to interpret dreams, which they regard as a source of symbolic clues to important unconscious feelings and conflicts. In addition, these therapists investigate the patient's life history, especially childhood memories.

There are a variety of methods of analytic psychotherapy other than psychoanalysis. For example, major variations of Freud's ideas and techniques were developed by Alfred Adler of Austria, Erich Fromm and Karen Horney of Germany, and Carl Jung of Switzerland. However, all analytic therapists focus on the interplay between the conscious and unconscious mind.

Behavioral psychotherapy is based on the concept that psychological problems result from a basic learning process called *conditioning.* In conditioning, a person learns to make specific responses to stimuli from the environment. According to behavioral theory, individuals who have psychological problems either have failed to learn effective responses to stimuli or have learned faulty behavioral patterns in dealing with stresses.

Behavioral therapists attempt to change a patient's self-defeating behavioral patterns by a variety of means. For example, the therapist may reward desirable responses and ignore or punish any other responses. Behavioral therapists also work to change patients' beliefs about themselves and their behavior. The therapist may try to increase a person's confidence in his or her own ability to function effectively. The therapist also may try to help a patient develop more reasonable goals.

Humanistic psychotherapy emphasizes people's potential for growth and self-fulfillment rather than concentrating on their unconscious conflicts or their self-defeating behavior. Humanistic therapists work to help patients develop personal awareness, self-understanding, and an appreciation of their own worth. The therapist does not probe the patient's past life, as a psychoanalyst does, or attempt to change specific behavior, as a behavioral therapist does. Instead, the therapist provides an atmosphere of acceptance and support where the patient can explore his or her problems.

There are several types of humanistic psychotherapy. The most typical one is probably *client-centered therapy,* which was developed by the American psychologist Carl R. Rogers. Rogers thought the word *patient* implied illness, and so he referred to the person seeking help as a *client.* Client-centered therapy assumes that the troubled individual is the best expert for solving his or her own problems. The therapist repeats and restates the client's feelings and thoughts in an effort to help the person gain insight. The therapist does not try to explain the problem or tell the client what to do. According to Rogers' theory, clients can learn to make constructive choices by becoming more aware of their emotions.

Other forms of psychotherapy include (1) Gestalt therapy, (2) transactional analysis, and (3) reality therapy. Gestalt therapy, developed by the German psychiatrist Frederick S. Perls, is directed at bringing patients' thoughts and actions into harmony with their deepest feelings. In transactional analysis, the therapist helps patients analyze their relationships in family and social situations. In reality therapy, the patient is held responsible for his or her own behavior and is forced to accept its consequences.

Group therapy is psychotherapy conducted with a group of patients, usually from 4 to 12. Any approach to psychotherapy may be applied in a group setting. For example, there are psychoanalytic therapy groups, behavior therapy groups, and Gestalt groups. Group therapy has several advantages. A therapist can serve more people in a group than in individual sessions, and they can share experiences and learn from one another. The group also provides social and emotional support to its members in times of stress.

In *family therapy,* one or more therapists work with the members of a family as a group. The therapists also may hold meetings with individual family members. Family therapists believe that even if only one family member seems to have a problem, all the members are involved in some way.

cines because of its laxative qualities. One species, *Plantago ovata,* is used in some breakfast cereals.

Some medical researchers believe that seeds from *P. ovata* may help lower the level of cholesterol in a person's bloodstream. Some cereal companies have added the seeds from this plant to their products and have used the medical claim in advertisements. Doctors consider people with high cholesterol levels at high risk of having a heart attack. The United States Food and Drug Administration (FDA) has not confirmed psyllium's effect on cholesterol levels. The FDA also fears that too much psyllium in a diet could cause health problems.

Richard C. Keating

Scientific classification. Psyllium plants belong to the plantain family, Plantaginaceae.

PT boat was one of the smallest, fastest, and most maneuverable fighting ships of the United States Navy. The letters PT stood for *patrol torpedo,* which meant that the craft carried out patrol duties and also carried torpedoes for combat. PT boats were often called *mosquito boats,* because they "stung" the enemy with great speed, and were most deadly in the dark.

In World War II, which the United States entered in 1941, PT boats made a remarkable record. They destroyed over 250,000 long tons (254,000 metric tons) of Japanese shipping. General Douglas MacArthur, his wife and child, and various officers and statesmen fled from the Bataan Peninsula to the island of Mindanao in PT boats in March 1942, on their journey from the Philippines to Australia. Future President John F. Kennedy was awarded the Navy and Marine Corps Medal for heroism and leadership after the boat he commanded, *PT-109,* was sunk by a Japanese destroyer in 1943.

PT boats were taken from the active list in 1959. However, in 1962, two boats had their torpedo tubes removed to increase their speed. These boats were put back on the active list as *PTF boats* (patrol torpedo boats, fast). The Navy acquired 24 other PTF boats between 1962 and 1968. Most of these ships saw service in the Vietnam War throughout the 1960's. They were later replaced by newer and smaller types of patrol craft. No PTF boats remain in the Navy today.

National Archives

The U.S. Navy PT boat was a speedy patrol craft. These boats won fame during World War II for attacks on Japanese shipping.

The PT boats used in combat by the Navy during World War II measured 77 to 80 feet (23 to 24 meters) long and about 20 feet (6 meters) across at their widest part. They were powered by three supercharged gasoline engines, each capable of 1,250 to 1,500 horsepower (930 to 1,120 kilowatts). The boats could reach up to 43 knots (nautical miles per hour). PT boats carried crews of 12 to 17 men.

PT boat hulls were basically different from those of other warships. They were called *planing* hulls because they skimmed or planed on the water surface. Larger ships cut through the water and will not rise up on the surface. They have *displacement* hulls.

PT boats, although much larger than high-speed, outboard-motor runabouts, had similar hulls. They were broad beamed, with a shallow *V*-shaped bottom. This design made PT boats of little use in rough or choppy water. Their high rate of fuel consumption limited their range. PT boats carried small, multipurpose guns, and sometimes rockets, in addition to torpedoes. Their most efficient use was restricted and the Navy kept few on active duty in peacetime. Jack Sweetman

Ptarmigan, *TAHR muh guhn,* is the name of a group of birds that live in northern parts of the Northern Hemisphere, such as Alaska, the Aleutian Islands, and Greenland. A ptarmigan can be recognized by the covering of short feathers on its feet. These feathers help it to travel across the snow. In winter, its feathers are white, and the bird often hides in snowbanks for protection. In summer, its feathers are reddish-brown and black. Ptarmigans build their nests on the ground. The nest is lined with grass or leaves. The females lay from 4 to 15 eggs. The eggs may be cream colored or red and are covered with black or dark brown spots.

Three kinds of ptarmigans live in North America. They are the *white-tailed ptarmigan,* the *rock ptarmigan,* and the *willow ptarmigan.* The white-tailed ptarmigan lives in the Rocky Mountains from central Alaska to New Mexico. The rock ptarmigan lives in the Arctic from the Aleutian Islands to Greenland. The willow ptarmigan makes its home in the Arctic, in the Canadian provinces of British Columbia and Newfoundland and Labrador, and in northern Europe and Siberia. The willow ptarmigan is the state bird of Alaska (see **Alaska** [picture: The state bird]). Bertin W. Anderson

Scientific classification. Ptarmigans belong to the subfamily Tetraoninae in the family Phasianidae. North American ptarmigans are genus *Lagopus.* The white-tailed ptarmigan is *L. leucurus;* the rock is *L. mutus;* and the willow is *L. lagopus.*

See also **Bird** (pictures: The ptarmigan hides from enemies; Birds of the Arctic).

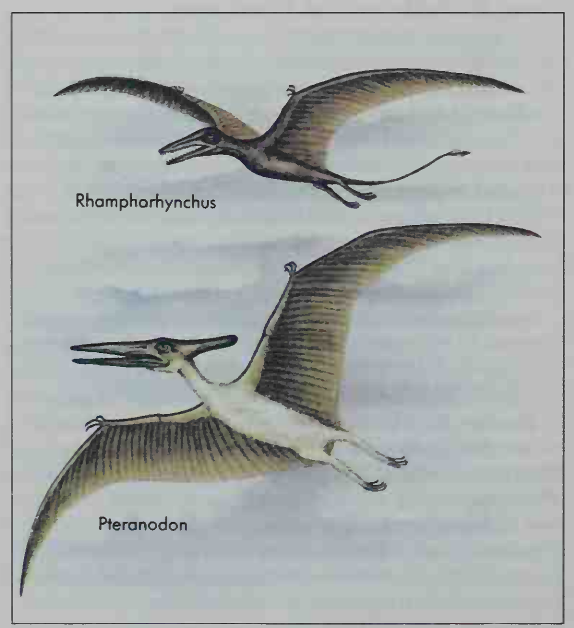
Pteranodon. See **Pterosaur.**

Pteridophyte, *TEHR uh duh fyt* or *tuh RIHD uh FYT,* is one of a large and important group of plants that are simpler in their structures than flowering plants. The name *pteridophyte* means *fern plant.* Not all the pteridophytes are ferns, but ferns are the best known of the group.

The pteridophytes lack flowers, but they have many of

the same tissues and habits that flowering plants have. Their organs are distinctly divided into roots, stems, and leaves, as those of flowering plants are.

Instead of reproducing by seeds as flowering plants do, the pteridophytes multiply by means of very small bodies called *spores* (see **Spore**). These spores do not result from flowers, but grow on special parts of the plant in little capsules. The spore capsules of ferns are the roundish, brown specks on the back of certain of the fern leaves. When the spores drift away and begin to develop, they produce small plants quite different from the ferns. After a time these small plants give rise to young ferns, which grow and produce another generation of spores. This process is known as *alternation of generations* (see **Alternation of generations**).



Other plants that belong to the pteridophyte group include horsetails, club mosses, and ground pines. These pteridophytes have a life history that is similar to that of the ferns.

Millions of years ago the pteridophytes were among the largest and most common kinds of plants. Many of the world's coal deposits contain large amounts of pteridophyte remains. Fossil records show that many pteridophytes reached the size of large trees. But present-day kinds, except the tree ferns of the tropics, are small, nonwoody herbs. David H. Wagner

See also **Club moss; Fern; Horsetail.**

Pterosaur, *TEHR uh sahr,* was a member of an extinct group of flying reptiles. Pterosaurs lived in the Mesozoic Era, from about 248 million to 65 million years ago. Their fossils have been found on every continent.

There were two major kinds of pterosaurs—*rhamphorhynchoids* and *pterodactyls.* Rhamphorhynchoids developed first. They had a short face and neck and a long tail. This group included some of the smallest pterosaurs, which were about the size of sparrows. Pterodactyls were more advanced and varied in size.

WORLD BOOK illustration by Oxford Illustrators Limited

Pterosaurs were prehistoric flying reptiles.

They had a long face and neck, and were almost tailless. The *Pteranodon,* a large pterodactyl, had a crest at the back of the head. The largest known flying animal was a pterodactyl. Its wingspan ranged from 36 to 39 feet (11 to 12 meters).

At one time, experts believed that pterosaurs flew poorly and used their wings only for gliding. Most scientists now think pterosaurs were good fliers that flapped their wings up and down. Only some of the larger and more specialized forms seem to have been suited chiefly for soaring and gliding. Pterosaurs had light, hollow bones. Three clawed fingers and a long fourth finger extended from the end of each forelimb. Each wing consisted of a membrane that stretched from the side of the body to the tip of the fourth finger. Fine, parallel fibers prevented the wing from tearing. Fur may have covered the pterosaur's body and kept the animal from losing body heat. Pterosaurs may have been able to run on their hind legs, but probably they were clumsy on land.

Pterosaurs ate other animals. The smaller forms probably ate insects. Some of the larger pterosaurs fed on fish, lizards, and other small *vertebrates* (animals with backbones). Keith Stewart Thomson

See also **Fossil** (picture: A fossil *Pterodactylus*).

Ptolemy, *TAHL uh mee* (A.D. 100?-165?), was one of the greatest astronomers and geographers of ancient times. He was also known as Claudius Ptolemaeus. Almost nothing is known about his life. But scholars have determined that he made his astronomical observations in Alexandria, Egypt, about A.D. 150. Ptolemy's observations and theories are preserved in a 13-part work entitled *Mathematike Syntaxis,* or *Mathematical Composition.* This work was so admired that it became known as the *Almagest,* meaning *the greatest.*

In the *Syntaxis,* Ptolemy rejected the idea that the earth moves. He pointed out that the earth is spherical and claimed that everything in the universe moves either toward or around the earth's center. For example, heavy objects fall in straight lines toward the earth's center. And, according to Ptolemy, the moon, sun, planets, and stars move around the earth at various rates of speed. Ptolemy believed that the stars were fixed points of light in a rotating sphere. Against this background of stars, Ptolemy traced the motions of the planets and worked out a theory for each of them. He stated that the planets are much closer to the earth than the stars, but are farther away than the moon. Ptolemy developed his system of astronomy largely from the ideas of the Greek astronomer Hipparchus (see **Hipparchus**).

Ptolemy's system of astronomy was accepted as authoritative throughout Europe until 1543. That year, the Polish astronomer Nicolaus Copernicus formulated his theory that the earth is a moving planet. Copernicus showed that Ptolemy's system was based on questionable assumptions and arguments (see **Copernicus, Nicolaus**).

Ptolemy devoted two parts of the *Syntaxis* to a catalog of the stars. He described a mathematical arrangement of the stars and gave the celestial latitude and longitude, as well as the *magnitude* (brightness), for each of them. This catalog included 1,022 stars grouped into 48 constellations. Ptolemy also discovered the irregularity of the moon in its orbit.

Ptolemy dealt with certain technical aspects of astronomy in his other writings. His serious treatment of astrology helped to spread belief in astrology as a scientific field. In his *Optics,* Ptolemy provided an extensive treatment of light and vision. He also dealt with reflection from various types of mirrors and studied the *refraction* (bending) of light as it passes from one medium to another.

Ptolemy's *Geography* opens with an excellent theory of map projection. The book lists places with their longitudes and latitudes. It also contains a map of the world, including Europe, northern Africa, and most of Asia, as well as 26 maps of specific areas. Ptolemy exaggerated the land mass from Spain to China and underestimated the size of the ocean. This mistake encouraged Christopher Columbus to make his famous voyage in 1492.

A. Mark Smith

Ptolemy I, *TAHL uh mee* (367?-283? B.C.), founded a family of rulers who reigned in Egypt from 323 to 30 B.C. This family became known as the Ptolemies. Ptolemy I, who took the title of king of Egypt about 305 B.C., ruled until 285 B.C.

Ptolemy was born in Macedonia, a region north of Greece. He became a leading general in the army of Alexander the Great, a Macedonian king who built an empire that included Egypt and most of western Asia. After Alexander died in 323 B.C., Ptolemy gained control of Egypt. He extended his rule to the island of Cyprus, Judea (in the southern part of ancient Palestine), and Cyrene, a Greek colony in northern Africa.

Ptolemy helped Egypt become a strong, independent country. He introduced new crops and improved existing ones. He encouraged trade and regulated imports and exports. Ptolemy recruited Greek and Macedonian settlers for his army, navy, and administration. He gave the settlers land and encouraged the development of Greek culture in Egypt.

Ptolemy founded a museum and library in Alexandria that helped make the city one of the world's great centers of culture and learning. Ptolemy also founded the cult of the god Serapis, which combined Greek and Egyptian practices (see **Serapis**). Donald Engels

PTSD. See **Post-traumatic stress disorder.**

Pu Yi, *poo yee* (1906-1967), often called Henry Pu Yi, was the last emperor of China. In 1912, when he was 6 years old, he gave up the throne after a revolution overthrew his Manchu government and established a republic. Pu Yi was allowed to remain in Beijing, the capital. But in 1924, he fled from warlords to Japanese protection in the nearby city of Tianjin. In 1931, the Japanese seized a large part of northeastern China and made it a puppet state called *Manchukuo.* In 1934, they made Pu Yi ruler of Manchukuo. He ruled until the end of World War II in 1945. The Soviets captured him and turned him over to the Chinese Communists, who pardoned him in 1959. Pu Yi was born in Beijing. Arif Dirlik

Public defender is an official paid by the state to defend people who are accused of a crime and are too poor to hire their own lawyer. Criminal defendants have a constitutional right to such legal representation and must be informed of that right when they are arrested. Most public defenders have only criminal jurisdiction.

The first public defender was appointed in Los Angeles County, California, in 1914. Public defenders are fairly common today, but many courts appoint local, private attorneys called *assigned counsel,* who often must serve without pay to defend the poor. Jack M. Kress

See also **Court** (How courts work).

Public domain is a legal category that covers government-owned land as well as creative works that the public may use freely. The creative works that may fall in the public domain include any scientific, artistic, or literary creation or invention. Such works are also called *intellectual property.* This article focuses on intellectual property that is in the public domain. For more information on public-domain land, see **Public lands.**

When intellectual property is in the public domain, anyone can use, make, or sell it without paying royalties or becoming liable in a lawsuit. Laws governing such property are, by treaty, the same in almost all countries.

All intellectual property begins as *proprietary material* —that is, material owned exclusively by a person or company. Different types of intellectual property enter the public domain in different ways. A chemical, mechanical, or electrical invention enters the public domain if it is sold or publicized and no patent application is filed within a year. If patented, the invention passes into the public domain when the patent expires. Copyrighted material enters the public domain when its copyright runs out. A trademark passes into the public domain if its use has been permanently discontinued or if the trademark has become widely used as a generic term. David Pressman

Public health is the general health of all members of a community. The term also refers to a community's efforts to prevent and cure illness and maintain the health of its people.

The governments of many nations have established public health agencies. The functions of these agencies vary from country to country, depending on the nation's level of technological development and its specific health problems. In addition, international health organizations conduct research and work to solve public health problems throughout the world.

In the United States, agencies of the federal, state, and local governments take part in public health programs. The federal government supervises public health care through the agencies of the Public Health Service (PHS), a division of the Department of Health and Human Services. All the state governments and many local governments have a department of health or department of human resources that administers public health work. Voluntary health agencies and private health foundations also contribute to the field of public health. This article discusses chiefly the work of state and local public health departments in the United States.

Functions of public health agencies

Public health agencies in the United States care for the medical needs of individuals and also provide health

Alan Kaleta, Gamma/Liaison

Preventing disease is an important goal of public health agencies. Health department officials often vaccinate children against measles, polio, and other contagious diseases.

Jack Fields, Photo Researchers

Ensuring environmental safety is a part of public health. All states try to control air, water, and soil pollution. These officials are taking water samples to test for contamination.

services for the general community. Most communities are served by their local health department. The Public Health Service mainly assists state and local health agencies. It conducts research, provides scientific information, and works to combat unsafe foods and drugs and contagious diseases.

The functions of state and local public health departments vary with the needs of the communities served. A typical state health department has various divisions, each of which handles a different aspect of health care. The principal functions of these divisions include (1) health planning, (2) providing preventive family or personal health care services, (3) ensuring environmental safety, (4) inspection and licensing, (5) collecting vital statistics, (6) furnishing support services for health workers, and (7) supplying disaster services.

Health planning. The health planning division of a state health department figures out the proper use of services, personnel, and facilities in certain areas. Such uses depend on the needs of communities in those areas. Officials determine these needs on the basis of such factors as infant and overall death rates and *communicable disease* rates. Communicable diseases can be spread from person to person, and many communicable diseases may lead to epidemics if they are not controlled.

Providing preventive health care services is a state responsibility for people with special health problems. These individuals include infants and children, pregnant women, and the poverty-stricken. State health departments give them such preventive services as immunizations, programs that supply information about nutrition and general health care, and control of communicable and *chronic* (long-lasting) diseases.

A state may contract with local health officials or private nonprofit agencies to deliver preventive health services. The state also may arrange for certain individuals to be served by health centers operated by the federal, state, or local government. Some of these centers aid people who have psychiatric problems or are victims of drug abuse.

Ensuring environmental safety. State health departments have regulatory agencies that establish and enforce standards for housing, food quality, and control of environmental pollution. Some states combine all such agencies into one division, which may be called the Bureau of Environmental Hazards. This division also carries out rodent- and insect-control measures designed to prevent the spread of diseases carried by the pests.

Inspection and licensing. Public health departments enforce state and local ordinances that require inspection and licensing of health facilities to ensure proper care of patients. Such facilities include hospitals, clinics, nursing homes, and research laboratories. Health departments also regulate pharmacies.

Collecting vital statistics involves gathering and storing records of such human events as births, marriages, divorces, and deaths. These records also cover

Mike Keza, Gamma/Liaison

A public health laboratory helps public health centers and private physicians identify diseases and other health hazards. This technician is examining food for signs of food poisoning.

certain causes of death, including accidents and diseases. Vital statistics tell health officials what has happened in a community regarding all these matters and what is likely to happen. See **Vital statistics.**

Furnishing support services for health workers. Most state health departments maintain laboratories that help public health centers and private physicians detect communicable diseases. These laboratories work with the Centers for Disease Control and Prevention, an agency of the Public Health Service, in fighting the spread of disease. State health departments also support research programs and distribute health education materials to medical professionals and the public.

Supplying disaster services. In many states, the public health department coordinates the services needed when natural disasters and other emergencies occur. Such calamities include floods, tornadoes, hurricanes, and major airplane or railroad accidents. Each state has a basic disaster plan to ensure medical services, housing, pure water, sewage disposal, and communications in stricken areas. In some cases, a state may receive help from the American Red Cross, the Federal Emergency Management Agency, or other organizations that specialize in disaster management.

History

Public health problems began when people first established communities. Many ancient civilizations had methods of handling such matters as waste disposal, disease control, and the need for pure water. However, epidemics struck most societies.

More than 2,000 years ago, the ancient Greeks did much to safeguard the health of the people. For example, large cities hired physicians to provide medical care. But most health measures benefited only the upper classes and did little to help the poor.

After the Romans colonized Greece during the 100's B.C., they adopted many health care techniques of the Greeks. For example, the Romans assigned public physicians to towns, primarily to care for the poor. They also built water pipes, supplied pure water, and established hospitals.

Following the fall of the Roman Empire in the A.D. 400's, most European communities ignored public health. Many communities finally established public health programs during the 1800's after suffering numerous epidemics.

The United States paid little attention to public health until 1866, when a cholera epidemic struck the nation for the 18th consecutive year. The American Public Health Association was founded in 1872. In 1893, threatened by another cholera epidemic, New York City established the first U.S. public health laboratory based on the new science of microbiology. Many states and cities then built similar laboratories to fight epidemics of such diseases as diphtheria, tuberculosis, dysentery, typhoid fever, and scarlet fever.

Careers

Public health offers a wide variety of career opportunities. People trained for administrative responsibilities or as medical professionals, such as physicians and nurses, hold about half the positions in this field.

Most public health work requires a master's degree. Such professionals as public health nurses and nutritionists must have a graduate degree in their specialties. Most people who work in environmental health have a master's degree from an engineering or technical school. They specialize in such areas as air pollution, industrial hygiene, and general environmental protection. Physicians hold many administrative positions in public health. These positions are also open to people with a graduate degree in business administration, health services administration, public administration, or a similar field. Gwynne Roeseler Winsberg

Public Health Service (PHS) is a division of the United States Department of Health and Human Services. It includes eight primary agencies: the Health Resources and Services Administration; the National Institutes of Health; the Food and Drug Administration; the Centers for Disease Control and Prevention; the Substance Abuse and Mental Health Services Administration; the Indian Health Service; the Agency for Toxic Substances and Disease Registry; and the Agency for Health Care Policy and Research. These agencies work with state and local agencies, educational and research institutions, and private industry to conduct health research, control disease, and provide health information, education, and services. The PHS also works with other nations and international agencies toward solving global health problems.

The assistant secretary for health directs the PHS. Other top officials include the surgeon general of the United States, who promotes good public health techniques. The federal government began a health service for merchant sailors in 1798. This agency was formally established in 1870 as the Marine Hospital Service. It became the Public Health Service in 1912.

Public lands include all the territory owned by a national government. The United States government owns about 762 million acres (305 million hectares) of land, or about a third of the land area of the country. Most of the public lands are in the western part of the nation, with the largest amount in Alaska. Congress may use or dispose of it in whatever way it feels will best serve the public interest.

Public lands are divided into (1) public-domain lands and (2) acquired lands. *Public-domain lands* have never been privately owned. They are what remains of the land acquired by the U.S. government from the 13 original states and from other nations. *Acquired lands* are lands the federal government has acquired from private owners and from state and local governments. Much of the land was purchased for such purposes as government buildings and defense installations. About 703 million acres (281 million hectares) of U.S. public lands are lands in the public domain, and about 59 million acres (24 million hectares) have been acquired.

The government reserves some of the public lands for military and naval installations, reclamation projects, wildlife refuges, federal buildings, and national cemeteries, forests, monuments, and parks. The term *public lands,* however, commonly applies to land that the government will lease or sell to private individuals. It does not include land that has been set aside for national parks and other uses. Since the United States became a nation, more than 1 billion acres (400 million hectares) of public land have been sold, granted to homesteaders, or otherwise turned over to private owners.

Management of public lands

Most of the public lands in the United States are administered by the Bureau of Land Management in the Department of the Interior. But many other federal agencies, including the Department of Agriculture and the Department of Defense, have jurisdiction over some public land. The Bureau of Land Management occasionally sells some of its land at public auction or trades it for land that connects other public lands.

In surveying public lands, the government divides an area into units of 36 square miles (93 square kilometers), called *townships.* Each township is further divided in a checkerboard fashion into 36 sections of 1 square mile (2.6 square kilometers). Each section, containing 640 acres (259 hectares), is divided into quarter sections of 160 acres (65 hectares). To help locate and describe any particular piece of land, surveyors use certain meridians of longitude (north-south lines), called *principal meridians,* and certain parallels of latitude (east-west lines), called *base lines.* All townships lying in a line from north to south are described as a *range.* See **Westward movement** (The Ordinance of 1785; illustration).

History

Acquisition of public lands. Between 1781 and 1786, the federal government gained control over a large area west of the Allegheny Mountains and north of the Ohio River. Four eastern states had claimed all or part of this region during the colonial period. By 1802, other seaboard states ceded what is now the states of Alabama and Mississippi.

The purchase of Louisiana in 1803 almost doubled the size of the United States. Other important additions of territory include the acquisition of Florida in 1819, the annexation of Texas in 1845, the acquisition of Oregon in 1846, the cession by Mexico of a vast territory between Texas and the Pacific Ocean in 1848, the Gadsden Purchase in 1853, the purchase of Alaska in 1867, and the annexation of Hawaii in 1898. Almost all this land became part of the United States' public lands. Texas and Hawaii retained control of the public lands within their borders, because they had been independent nations.

Disposal of public lands. As early as 1783, land companies tried to purchase public lands for the purpose of establishing settlements in the area north of the Ohio River. Their actions forced Congress to formulate a policy for the disposition of public lands. In the Ordinance of 1785, Congress adopted policies intended to produce revenue and encourage compact settlement. The ordinance also established a permanent method for surveying. The land policies expressed in this law represented the views of Easterners, and soon proved unpopular in the West. Under pressure from Western members of Congress, later land laws permitted purchasers to buy a specified minimum amount of land at a low price. The laws encouraged pioneers to buy and settle on any public lands that had been surveyed.

An important development in land policy came in 1862, with the passage of the Homestead Act. It provided that people who lived on public lands for five years and made certain improvements might acquire title to 160 acres (65 hectares) through the payment of very small fees. This law made it possible for workers in Eastern cities to move west and own farms of their own.

Individual settlers were not the only people interested in obtaining grants of public land. Land companies and speculators bought large tracts of land to sell to people who wanted new homes in the West. After 1850, corporations and individual promoters tried to gain control of large acreages for grazing, mining, logging, or control of other natural resources. Such groups acquired much of the public land in the Far West.

The government also used the public lands to promote certain of its own objectives. It offered free land to veterans of every war from the American Revolutionary War through the Mexican War. It granted land to the states for the support of public education. The Morrill Act of 1862 gave to each state an amount of land in proportion to its population for the establishment of agricultural colleges (see **Land-grant university**). The government also gave generous grants of land to railroads along proposed rights of way to encourage railroad building west of the Mississippi River.

By 1890, nearly all the good farmland had passed into private ownership. But private owners acquired large amounts of other land under the Homestead Act until the mid-1930's. In 1976, the U.S. government ended the homesteading program in all states except Alaska. It expired there in 1986.

Public opinion can help bring about various reforms by putting pressure on government leaders. The protesters shown at the left are calling for an end to the production of nuclear arms.

Public opinion refers to the opinions or views of people in a community or country on issues of public interest or concern. Such issues may deal with any subject that is open to differing beliefs and attitudes. For example, it is a matter of *opinion* whether the nations of the earth should attempt to cooperate in some sort of international organization, and, if so, what form this organization should take. In matters of opinion, reasonable people may hold widely different viewpoints.

On the other hand, it is no longer considered to be merely a matter of opinion that the earth is a sphere rotating on an axis and revolving in an orbit around the sun. It is a matter of *fact,* which can be demonstrated and about which reasonable people do not differ.

When a problem affects a number of people, they will discuss it and argue about it. These activities help develop a common opinion, or *consensus.* When discussion is open or public, these matters are public opinions. Public opinion, in this sense, varies widely in its character and content. Public opinion may be merely the variety of individual opinions in the early stages of discussion, when issues are not sharply defined and people are not well informed about them. At other times, the opinions of many individuals may become similar enough to form a *majority opinion* or even a consensus, which determines the kind of action a group will take. A vote decided by the majority gives structure to the group opinion and makes it lawful.

There is no definite way in which public opinion affects the decision-making process of government leaders and groups. Elections of political leaders are one important way the public can express its judgment about a candidate. However, the process of shaping government policy is often slow and uneven. Expressions of opinion may influence politicians. But such expressions also may be disregarded because public opinion lasts only a short time, is emotionally charged, and usually represents the more visible and vocal portion of the population. The balance of the population, often called the *silent majority,* does not express its views as regularly or as visibly.

Nevertheless, one of the major concerns of a democratic society is to determine the extent and significance of the opinions held by individuals and groups. The most common technique today, the public opinion poll, is used to survey the opinions of a sample of the population. The accuracy of the results depends on the knowledge and skill of the pollsters in selecting the sample and in developing good interview questions. There is always some margin for error in the results.

There is no one "public"

A *public* is any group of people within which a controversy arises. They are the people who take part in the controversy and who are, or may be, affected by the way in which the controversy is finally settled. This group may be fairly stable or organized, such as the residents of a local community or the citizens of the United States. A public may also be made up of a number of individuals who are unorganized and hard to identify, but who for widely varied reasons have a common interest in the matter at issue. Sometimes a public may be so small and compact that discussion takes place almost wholly through conversation and speechmaking in face-to-face situations.

Today, however, when modern means of communication make vast numbers of people aware of controversial issues and common interests, publics tend to be large and impersonal. These publics involve people who are not known to one another and are widely distributed over the country, or even among a number of countries. The members of such publics rarely meet each other face to face or have much direct communication. They are held together by the press, radio, television, motion pictures, and other means of communication. These impersonal but powerful publics are numerous in today's highly complex society. Many of them have their own specialized means of communication—newspapers and magazines, sponsored radio and television programs, and local and national organizations representing opposing sides in controversies about issues.

The same person may be a member of several of these publics at one time. An individual may thus take

part in discussions on a number of different problems and develop opinions in one area that conflict with those held on other subjects. An opinion about some economic issue, for example, may not be wholly in agreement with other opinions about moral, religious, or political issues. Intense public controversies sometimes arise out of efforts to reconcile opinions about problems in one field with opinions in others.

The process of forming opinion

Many factors affect the position people will take on any public issue. People's values and attitudes influence the opinions they hold. Some people are well informed or make an effort to become so, and others make quick judgments based on casual impressions. Some people act quite independently. Yet other people are influenced mainly by the views of their friends and associates. Equally well-informed people often form differing opinions because they interpret facts differently, or because they have different interests, desires, anxieties, and prejudices.

Some individuals, especially celebrities, frequently have much more influence than others in the process of opinion formation. Such a person often appears to know all the facts and to have an outstanding ability to determine how they should be dealt with. Thus, this person may boldly and aggressively urge people to support a particular idea or course of action. Leadership may also be taken by unknown or ordinary people who, either as individuals or as small groups, spread their ideas slowly by word of mouth. In time, they can make a deep impression on the opinion of the masses of people.

Events also may have a great effect on the forming of opinion if they are dramatic enough, near enough, or personal enough to attract the attention of large numbers of individuals. The Great Depression of the 1930's focused public attention sharply on the need for economic reforms. Unemployment and widespread need changed more opinions than hundreds of lectures, radio talks, editorials, or sermons ever would have done. Various controversial topics quickly generate public opinion responses. Such topics include gun control, abortion, drug legislation, government authority, and foreign policy issues. Issues affecting war and peace are also a powerful force in influencing public opinion.

Agencies of public opinion

An agency of public opinion is simply the carrier of information about public issues, and of views about these issues. The agency may be an individual, a group of individuals, or a mechanical device that helps them to communicate with other people. An agency of public opinion is not necessarily its originator or maker, but it may be so.

The oldest agency of public opinion is what Walter Bagehot, an English publicist of the 1800's, called *common talk.* Ordinary conversation among friends and acquaintances on the street, in public meeting places, in homes, or elsewhere is still a powerful agency in forming public opinion. In early times, word of mouth was almost the only carrier of public opinion. It was only a step from friendly group discussions to the oration or the sermon, in which one person more skilled at thought and expression than the rest undertakes to organize and state the prevailing opinion on some particular issue or problem for the group.

The press. Speeches, books, and pamphlets were the principal means of expressing opinion until the 1800's. Then newspapers appeared in large numbers and soon developed wide circulations. The newspaper became more powerful than any other agency as a carrier of public opinion. Each newspaper usually builds its own group of readers who depend on it for news and opinion about public affairs. Its power within the public is great, but this power is limited by rival newspapers with other points of view. Magazines are also powerful in making public opinion.

The political cartoon is a powerful tool for expressing and molding opinion in the press. The cartoonist can caricature prominent people and ideas, and thus can often express a point of view more bluntly and much more vigorously than it could be expressed in writing. Most cartoons appeal more to the emotions than to reasoned and informed analysis.

The motion picture is another important agency of public opinion. It has the advantage of giving people a vivid and concrete presentation of people and events that otherwise could be known only through oral or printed reports. Audiences are introduced intimately to manners, customs, ideas, and ways of life that may be much different from their own. Many screenplays also express a point of view toward issues. Newsreels, travel pictures, documentary films, and other special kinds of motion pictures have been widely used to spread news and propaganda. The visual approach often affects the emotions of the audience and generates a strong response.

Radio and television carry the voices and words of newscasters and commentators—and of newsworthy people themselves—directly into millions of homes. They also bring into the home pictures of events as they occur. Radio and television have supplemented rather than replaced the newspaper and the motion picture as carriers of news and opinion. The older means of communication have time to give a more studied, fuller version of events than can the immediate reporting to which radio and television are best adapted.

Educational agencies. Schools and other educational institutions have great importance among the agencies of opinion. Their importance lies partly in their ability to develop basic attitudes and points of view that have a great bearing on the opinions people will form about the issues that arise from day to day. They provide knowledge about social, economic, political, and other aspects of life, and equip people with the skills necessary to interpret information about current developments.

Other agencies. The making of public opinion by special propaganda groups has by no means disappeared from modern society. The most important of these groups are those with political, economic, or religious interests. There are also less powerful groups that create ethical, nationalistic, racial, literary, artistic, and other types of public opinion. See **Propaganda.**

Political opinion is made for the most part by or for the political parties. Every large political party has an elaborate propaganda machine. Even the government in

power, whether local or national, feels obliged to create a public opinion favorable to itself so that its program may be carried out.

The making of public opinion by economic groups is also important in modern society. Business and economic institutions constantly seek to create and maintain a public opinion favorable to their interests. Businesses are especially active in the endeavor to sell more goods and services. In doing so, they use advertising, sales promotions, and public relations to create favorable public opinion toward their products and business itself. Labor groups, farmer groups, and even consumers themselves are often organized for the purpose of developing public opinion powerful enough to have substantial influence.

Public opinion and government

If people are going to live together in society, they must set up certain rules, regulations, and controls to give that society some permanent form. In this way, the society can carry on its life with little conflict or disorder. In a dictatorship, the controls set up are forced on the majority of the people by a small group who control the instruments of power. The people have little or no voice in deciding what kinds of controls are to be used. But in a democracy, the controls rest on the voluntary consent of at least a majority of the members of society.

In many early societies, and in some countries today, leaders have used force or violence to make the people accept the rules. In some cases, the mere threat of violence is enough. Some leaders have used fraud to deceive the people. To protect their people from fraud, governments have extended laws against this abuse to include unethical practices in medicine, advertising, selling, and other fields. See **Fraud**.

Propaganda and censorship are the most widespread governmental controls over public opinion. With propaganda, the government seeks to make people accept its program and policies by persuading them that only such a program will keep them out of danger, or win a war, or meet some other emergency. Propaganda is actually a means of creating public opinion, rather than simply controlling it. Censorship, which seeks to eliminate ideas and attitudes, is a negative control over public opinion. It is often coupled with *counterpropaganda,* designed to meet the threat of one particular idea with one more favorable to the government. See **Censorship; Propaganda.**

Democratic society requires the abandonment of the older, cruder, and less reasonable controls. Instead, an informed and intelligent public opinion is regarded as the best means of securing orderly conduct and cooperation among people. Public opinion becomes the ultimate controller of social goals, laws, and ways of life. Democracy as an ideal is government by an enlightened public opinion. The average person in any society recognizes that everyone must live up to certain rules in society in order that each person can live in peace and freedom. An individual with this point of view is likely to resist any individual or group that seems to be trying to gain an excessive share of control in the whole society. The spread of education and the development of the newspaper, radio, and television have made it possible for more people to learn more about issues and events in their society. People can then react effectively to these conditions and developments.

Controlling public opinion

There is little doubt that public opinion has the potential to be a powerful means of forming social behavior in the modern world. Every group ambitious to rule or to exploit the masses of the people attempts to capture and control public opinion.

Democracy depends on a balance of power of different groups rather than upon the power held by one or a few groups. Its basic controls will therefore be designed to secure for its citizens freedom to know the facts about public matters, to secure full and free public discussion, and to make public decisions effective.

In the United States, a number of such controls exist. For example, the Constitution provides for a careful system of checks and balances. The president is balanced by Congress and the Supreme Court. Congress is balanced by the president and the Supreme Court. The Supreme Court is balanced by the president and Congress. In addition, the framers of the Constitution realized that further safeguards were needed to protect the individual against any single group that might seize power. The first 10 amendments, known together as the *Bill of Rights,* were added to the Constitution as a further protection of the opinions, privileges, and opportunities of citizens (see **Bill of rights**).

One of these amendments assures freedom of speech, press, and assembly. This freedom has been jealously guarded throughout U.S. history. Congressional hearings, other public agencies, and private organizations also work to provide individuals and groups with the opportunity to present their views.

An effective and progressive democracy depends on an enlightened public opinion. The surest and most constructive development of public opinion is education, both in the schools and in other agencies of public opinion. The freedoms and liberties that a democratic society provides also impose a number of responsibilities on the citizens of a democracy. Citizens must see the relationships among their own individual welfare, the proposals of the government, the interests of special groups, and the goals of the nation as a whole.

Extensive and accurate information is democracy's greatest ally, just as it is the greatest enemy of antidemocratic forms of government. Such information helps people make sound, informed judgments. Then they will also find it easier to see through the aims and devices of those who attempt to manipulate public opinion for selfish interests rather than the public good.

A public opinion poll measures people's attitudes about various issues. A personal interview conducted by a trained interviewer, *above,* is probably the most reliable method of polling.

ions will usually accurately reflect those of the entire group.

Public opinion polls ask many kinds of questions. For example, a poll before an election may ask people whom they plan to vote for and why. Other polls may ask people if they plan to buy a new car and what kind of car they want.

Polls are conducted throughout the world. But they are most frequently taken in developed countries with a democratic form of government.

Who uses polls?

Public opinion polls are used chiefly by five types of groups: (1) news media, such as newspapers, magazines, television, and radio; (2) politicians; (3) business companies; (4) government agencies; and (5) social scientists. These groups generally use polls that are taken by private polling companies, university research centers, or government agencies. Some groups conduct their own polls.

News media publish or broadcast the findings of public opinion polls. The major television networks and national newspapers conduct their own polls. Broadcasting stations and newspapers also subscribe to polls such as those conducted by The Gallup Organization and Louis Harris and Associates.

Politicians use polls to help them plan their election campaigns and keep track of their strength with the voters. Polls help elected officials make decisions by telling them how people feel about various problems and issues. Many political candidates and elected officials hire polling groups to conduct private polls for their own use.

Business companies use polls to help them manage their operations and sell their products. Large numbers of businesses study the various polls that appear in the news media. Some companies also subscribe to special polls taken by private polling companies. Many advertising agencies conduct *market research polls* that measure people's knowledge and opinion of a product.

Government agencies rely on polls for guidance in operating and evaluating their programs. Such polls ask people's opinions on educational programs, medical services, transportation, and other subjects.

Social scientists sometimes use polls when studying human behavior. A psychologist might conduct a poll among different age groups to study differences in attitudes between younger and older generations.

Conducting a poll

People who conduct public opinion polls are sometimes called *pollsters.* The work of pollsters involves five steps: (1) defining the goals; (2) selecting the *sample,* the individuals to be questioned; (3) designing the questionnaire; (4) interviewing the sample; and (5) analyzing the results.

Defining the goals involves deciding what a poll will seek to find out and whom it will question. A poll may ask people's opinions about certain economic, political, or social issues. It may study people's attitudes toward various events, individuals, or situations. The group of people from which the sample is selected is called the *population* or *universe.* A population may consist of everyone in a city, state, or some other area. On the other hand, it may include only a certain group, such as factory workers, homeowners, or teen-agers.

Selecting the sample. Pollsters select the sample so that every person in the population has as close to an equal chance to be included as possible. When polls are conducted by telephone, they select the sample using *random digit dialing.* In this technique, phone numbers are picked by chance from among the possible phone numbers in the geographical area being polled. In polls conducted through personal interviews, pollsters first divide the area to be surveyed into major geographic regions. Specific localities are then selected by chance.

Within these localities, the pollsters select various neighborhoods by chance. Interviewers then conduct several interviews in each of these neighborhoods. In both telephone and personal interviews, pollsters also choose which member of the household to interview on a random basis.

Designing the questionnaire. Pollsters ask two general types of questions—*closed* and *open.* A closed question asks the respondents to select their answers from two or more choices. An open question asks them to give their opinions in their own words.

Before pollsters conduct a poll, they sometimes assemble a *focus group* of about 10 people to discuss the issue the poll will examine. The group's comments help pollsters to understand the public's attitude toward the issue so that they can make up an effective questionnaire. Most pollsters then pretest the questionnaire on a small number of people. By pretesting, the pollsters can tell if the respondents understand the questions, and if the answers provide the kinds of information sought. They also find out if the order of the questions affects the way people answer them.

Interviewing the sample. Most pollsters question respondents directly, either in person or by telephone. Such questioning ensures that all, or almost all, the people are interviewed. Questioning respondents in person has two advantages. The first one is that the interviewer can be at least reasonably sure that the respondent understands the questions. The second advantage is that the interviewer can use cards or other displays that list the choice of possible answers.

Telephoning respondents is the fastest way to conduct a poll, and it is less expensive than personal interviews. Some polls involve questionnaires that are mailed to respondents. However, many people do not return these questionnaires, and so mail surveys are usually not reliable measures of how the entire population feels.

Analyzing the results. Computers help quickly tabulate the pattern of responses to pollsters' questions. The most common tabulation shows the percentage of respondents who answered each question in a certain way. Analysis of the results can show how strongly people feel about various subjects and whether their opinions have changed since a previous poll. It can also show what differences of opinion exist between different segments of the population and how attitudes on different subjects are interrelated.

Evaluating a poll

The reliability of a poll depends chiefly on the size of the sample and how it is drawn. Most national polls involve interviews with between 500 and 2,000 people, depending on the purpose of the poll. If scientific procedures are followed in selecting the sample, the pollster can calculate *sampling error.* Sampling error is expressed as a range—a certain number of percentage points—above and below the reported finding of the poll. It is the range of results that could be expected if an infinite number of similar samples were polled on the same question. Sampling error depends on the size of the sample, not the size of the population.

Questions that are not fairly worded can also affect a poll's reliability. In addition, polls that have been sponsored by individuals who have something to gain by a certain result should be regarded cautiously.

History

An early survey of public opinion was conducted in the United States in 1824. The *Harrisburg Pennsylvanian* asked voters in Wilmington, Delaware, who they thought would be elected president that year. On the basis of the poll, the newspaper predicted that Andrew Jackson would win. Jackson received more electoral votes than any of his three opponents, but did not get a majority. As a result, the election went to the House of Representatives, which elected John Quincy Adams.

Polls following scientific procedures were first used in 1935 with the experimental nationwide surveys of George H. Gallup and Elmo Roper. Another pollster, Archibald M. Crossley, began conducting scientific polling methods the following year. In 1940, the first academic center for the development of polling techniques was founded by Hadley Cantril at Princeton University.

In the mid-1930's, two inaccurate presidential polls demonstrated the danger of relying on mail surveys and quota sampling. In 1936, the magazine *Literary Digest* mailed out 10 million questionnaires concerning that year's presidential election. Two million questionnaires were returned. Based on these replies, the magazine predicted that Governor Alfred M. Landon of Kansas would defeat President Franklin D. Roosevelt. But Roosevelt won in a landslide, and Crossley, Gallup, and Roper correctly predicted his reelection. The *Literary Digest* poll was inaccurate chiefly because the questionnaires were mailed to people chosen from telephone directories and from lists of car owners. As a result, wealthy people were overrepresented in the sample.

In 1948, polls based on quota samples predicted that Governor Thomas E. Dewey of New York would defeat President Harry S. Truman. However, Truman won reelection in one of the greatest upsets in U.S. history. The polls failed for two chief reasons. The last polls taken were conducted too long before the election, and many voters probably changed their minds. Also, the pollsters' quota samples did not accurately represent the people who voted. After the 1948 election, most pollsters began to use probability sampling. This change, along with refinements in interviewing and other procedures, greatly increased the reliability of polls.

Since the 1970's, two special kinds of polls, called *tracking polls* and *exit polls,* have been widely used during elections. Tracking polls are conducted with small samples toward the end of an election campaign. Candidates use these polls to follow changes in their standing with voters. Exit polls are taken as people leave their voting places. The news media use the information collected in exit polls to help interpret the results of an election. Albert H. Cantril

Public ownership. See Government ownership.

Public relations, often called *PR,* is an activity that uses communication to increase understanding between an organization or individual and one or more groups called *publics.* The term *public relations* is also applied to the profession responsible for handling such activities.

Corporations, educational institutions, entertainers, government agencies, labor unions, politicians, and religious groups are among those who use public relations. Their publics vary from employees and stockholders to entire communities and members of the media. Many organizations use public relations to gain the understanding of both their *internal public* (employees) and *external public* (customers).

Communication strategies range from simple news releases and fact sheets to sophisticated public relations campaigns featuring films, advertisements, speeches, and television appearances. Such communication is aimed at gaining the good will of the community.

The basis of any effective public relations campaign is public benefit. If an organization does not serve the needs of its publics, they will not support it. Public relations experts help organizations and individuals learn what their publics want and establish communication policies that reflect concern for the interests of those publics.

Public relations generally is practiced through (1) corporate public relations departments, (2) public relations firms or agencies, and (3) public information departments. In a corporate PR department, specialists handle PR activities only for that company. In PR firms, public relations practitioners carry out activities for several organizations or individuals, also called *clients* or *accounts.* Nonprofit organizations, such as colleges and government agencies, have public information departments that work to strengthen the organization's image and credibility.

Methods. Public relations focuses on two main activities, *research* and *communication.* Research is vital to public relations because organizations need to know their publics' opinions about them. What people think and why they have such opinions are important in helping management establish corporate and client policies and practices.

Public relations uses many research methods to obtain information. Researchers gather information on the many problems and opportunities facing a company, its industry, and the business community. They may also gauge public opinion to provide political candidates with issues to discuss during a campaign. Researchers also test PR campaign effectiveness and keep up with public relations techniques being developed by other companies or firms.

Communication between organizations or clients and their publics is an important part of public relations campaigns. However, the size and complexity of modern organizations makes direct communication with individuals almost impossible. Most organizations use mass-communication methods to reach their publics, often focusing their PR campaigns at groups of people who share a common interest.

PR professionals use four principal methods to communicate with their publics: *advertising, lobbying, publicity,* and *press agentry.* Advertising involves the use of paid, nonpersonal communication through such media as billboards, the Internet, mail, newspapers and other publications, radio, and television. Lobbying attempts to influence special publics, such as legislators. Publicity and press agentry involve promoting an organization or client by getting favorable media coverage.

Public relations professionals often detect possible breakdowns in communication by analyzing responses received from their publics. These responses may come directly, as in e-mail messages, letters, or telephone calls to an organization. The responses also may come indirectly, as when voters respond to a public relations campaign by casting their ballots for a candidate or when consumers respond by purchasing or refusing to purchase a product.

History. Some elements of public relations, such as informing and persuading, have been used throughout history. But public relations as it is known today began to take form during the early 1900's, after a period of rapid industrial expansion in the late 1800's. Upon the advice of public relations counselors, corporation leaders realized that the community's good will would benefit them. Business leaders also realized that successful public relations campaigns had helped the federal government and welfare agencies in winning approval for their programs. Corporations began to set up programs designed to win their publics' favor. Schools, hospitals, and other nonprofit organizations also saw the need for organized attempts to gain public support.

Public relations developed slowly until the mid-1900's. Since then, it has spread to nearly all corporate and nonprofit organizations. The growth and expansion of the mass media have tended to make public opinion more powerful than ever before. Today, an organization's internal and external publics are more accessible than ever to those who wish to reach them. This improved access is aided by the work of public relations.

Careers. Most public relations activities take place in business and industry. Colleges, labor unions, national associations, schools, and volunteer agencies also have public relations programs. An organization may have its own public relations department, or it may hire a public relations firm.

A college education best prepares a person for a public relations job. Employers seek people with degrees in English, journalism, or public relations. Many employers prefer applicants with backgrounds in fields related to the company's activities. People interested in public relations should be creative and able to express their thoughts clearly, both orally and in writing. Such a person also should possess good problem-solving abilities.

Public service. See **Careers** (Community and social services); **Economics** (Public services).

Public speaking is the art or practice of making a speech before an audience. In group or club events, there are many opportunities to make speeches. People who speak effectively are likely to become leaders. Training in effective public speaking is a key part of training for leadership in any field of activity.

Speakers who have a specific purpose and are successful in attaining it are said to be *effective.* If they try to inform, they are effective when the members of their audience understand the facts. If they try to persuade members of the audience to agree to do something or to change their opinions, the speakers are effective when members of the audience decide to take the action or when they do change their minds. If speakers try to entertain the audience, they are effective when the audience shows by applause or laughter that they are enjoying the speech.

Approach to a speech

Speakers must consider four points: (1) their subject, (2) their audience, (3) themselves as speakers, and (4) their occasion.

Subjects. The speaker's direct and indirect experiences are the two general sources of speech subjects. *Direct experience* is knowledge obtained by actual participation in events. *Indirect experience* is knowledge obtained from radio, television, reading, and listening to other people. Speakers can usually make a more effective presentation with subjects from their direct experiences. Subjects should stimulate speakers to their best efforts. At the same time, they must appeal to the audience and be keyed to the knowledge and experience of the listeners.

Subjects may be divided into three types: those which *inform,* those which *persuade,* and those which *entertain.* All are important.

Some examples of *informative* subjects are:

Basic principles of computers
The feeding habits of snakes
How steel is made

Some examples of *persuasive* subjects are:

The 12-month school year should be adopted.
The United States should abolish the Electoral College and adopt a system to provide for the direct popular election of the President.
Capital punishment should be abolished.

Some examples of entertaining subjects are:

Do teachers have private lives?
Inventions that never worked
Pets as members of the family

Audiences. Speakers must consider the knowledge and the wants of their audiences. They should find out what the members of their audience already know about the subject. The problem of explaining the operation and maintenance of a new microwave oven to a group of electrical engineers is different from explaining it to people who know little about electricity.

The speaker who attempts to persuade an audience should know their attitudes or opinions. If speakers know beforehand that their audience is opposed to their proposal, then they know that they face a different problem from that of persuading a favorable audience.

WORLD BOOK photo by Dan Miller

A public speaker should stand erect and speak loudly enough to be heard comfortably by every member of the audience.

Speakers should also know whether the members of their audience want to hear about a subject. People usually listen only when they think the speaker's ideas will be of some benefit to them.

Speakers. The speaker's personality is probably the most important factor in influencing audiences. Speakers should consider how the audience will view them.

Occasions. Speakers should think carefully about the time and place of their speeches. Is the occasion appropriate for the subject they have chosen? The meeting of a sailing club would hardly be an appropriate occasion for a speech designed to sell household appliances. However, such a meeting would be appropriate for a speech designed to raise money for new sailboats.

Planning the speech

When speakers have given careful thought to their subject, their audience, their own personality, and the occasion, they are ready to plan the speech itself.

Purpose. Speakers should first select their general purpose. Do they wish to present factual information only, or to *inform?* Do they wish to change beliefs or actions, or *persuade?* Or do they wish to amuse, or to *entertain?* With their general purpose in mind, they should prepare a brief statement of their specific purpose. Examples of specific purposes are:

Informative. Tell a class how steel is made.

Persuasive. Convince an audience that Congress should propose a constitutional amendment to abolish the Electoral College and to provide for the direct popular election of the President.

Entertaining. Amuse a school assembly with a humorous look at the private lives of teachers.

The main ideas. The next step should be to select the main ideas, or main divisions, of the subject as stated in the specific purpose. In informative speeches, the main ideas should define the specific purpose by answering the questions *who*? *what*? *where*? *when*? *why*? and *how*? In persuasive speeches, the main ideas ought to be the principal reasons for the desired belief or action. In entertaining speeches, the main ideas should be the divisions of the subject that can be amusing to the audience.

Supporting material. After selecting the main ideas, speakers should choose supporting material. This includes such things as *description, narration, comparisons, examples, testimony, statistics, visual aids* (charts, diagrams, demonstrations, slides, maps, motion pictures, photographs, samples, or working models), and *repetition* (restatement of important ideas to increase the chance that they will be remembered). The selection of main ideas and supporting material completes the *body* (main part) of the speech.

Introduction. Speakers should next plan the introduction. This usually has two parts, the opening and the statement of the specific purpose. In the *opening,* speakers catch the attention of their audience and arouse interest in their subject. They can do this by telling a joke or story, or by providing a fact or statistic. They may refer to an event, or to the present occasion, place, or audience (with humor or congratulations). They may quote something or ask a question. In their *statement of specific purpose,* they tell the audience precisely what they intend to do in their speech and what value this topic has for the audience.

Conclusion. Next comes the preparation of a conclusion. In informative speeches, this part should be a summary of the main ideas and specific purpose. In persuasive speeches, the conclusion should combine a summary with a final appeal to the audience to accept the arguments offered. Entertaining speeches usually end on a point of great amusement, without any type of formal conclusion.

Outline. After all these steps, speakers should prepare an outline. Here is a sample outline for the subject, Congress should propose an amendment to the U.S. Constitution to abolish the Electoral College and to provide for the direct popular election of the President.

Introduction

I. Opening

The American patriot Thomas Paine said, "Those who reap the blessings of freedom must undergo the fatigue of supporting it." Yet Americans today seem little concerned that the method of electing a U.S. President is undemocratic. Unlike other elected officials, the President is not directly elected by the people. The people elect presidential electors who have been chosen by their political parties to represent their party's candidate in the election. The presidential electors, in turn, choose a President. Under this system, the United States has elected three Presidents whose closest opponents received more popular votes than they did. In fact, a candidate could become President by winning in only 11 states—the 11 most heavily populated ones. This could leave the people in 39 states without a voice in the election. As a citizen you must be concerned that your voice may be stilled.

II. Purpose

The procedures for electing the President have been set down in the Constitution. To change the system, the U.S. Congress should propose a constitutional amendment. Several plans have come before Congress. Of these plans, the direct popular election plan is the most democratic and uncomplicated method of choosing a President. Thus, Congress should propose an amendment to abolish the Electoral College and to provide for the direct popular election of the President.

Body

I. The present system no longer suits the needs of the voters.

A. Delegates to the Constitutional Convention in 1787 agreed on the Electoral College system partially on the grounds that the public was not sufficiently informed to select the best person for President.

B. However, modern communications permit citizens to follow current events from day to day in newspapers and magazines and on radio and television.

II. A direct vote system would be more democratic.

A. Each voter would have an equal voice in choosing the President. The votes of citizens in heavily populated states would not carry more weight than the votes of those in other states.

B. The candidate with the most popular votes would become President.

III. If no candidate received a majority of the votes, a direct vote system would reduce the chances of political deals and an electoral crisis.

A. The present system could give a third-party candidate the power to control the outcome of an election.

B. The present system may delay the election of the President for two months after the general election.

C. A direct vote system would eliminate the danger of an unpledged elector voting against the candidate of the elector's party.

Conclusion

The Electoral College system of electing a President has proven dangerous, outdated, and undemocratic. The only system that would correct these flaws is a direct vote system. Therefore, Congress should propose an amendment to abolish the Electoral College and to provide for the direct popular election of the President.

Delivering the speech

Speakers may deliver their talks directly from the outline, or they may use the outline as the basis for a written speech. Skilled speakers usually prefer to speak from the outline, without writing the whole speech down.

A speech that is delivered from an outline, without being memorized, is said to be delivered *extempore,* or *extemporaneously.* Extempore speeches should not be confused with *impromptu* speeches. These types of speeches are made without any previous preparation, often without notice.

If speakers are properly prepared, they should feel at ease in front of an audience. They should relax and speak in a natural voice. They should stand erect, make eye contact with individuals in the audience, and speak loudly enough to be heard easily. In addition, speakers should vary the pitch and volume of their voice and their rate of speech to avoid being singsong or dull.

James M. Copeland

Public transportation. See Transportation (Public transportation).

Public utility is a company that provides an essential service to the public. Public utilities include firms that offer electric power, natural gas, telephone, telegraph, water, and sewerage services. Airlines, bus lines, railroads, and other transportation systems are also public utilities.

Most public utilities in the United States are privately owned. But in Canada and some European countries, a majority are owned by the government. Government ownership in the United States exists chiefly at the local level. For example, the governments of cities, towns, and counties own most airports and transit, sewage disposal, and water supply systems.

Most public utilities enjoy a certain amount of protection from competition. In the United States, this protection is granted by local governments and by local, state, and federal regulatory agencies. In a given geographical area, a protected utility often can provide a service more efficiently and at a lower price than could several companies competing with each other. Vigorous competition may result in higher prices because each competing company may have to buy the same type of expensive equipment while serving fewer customers than would be served by a single, protected company.

Government regulation. Public utilities that enjoy protection from competition must be regulated to ensure that they charge reasonable rates and provide adequate service to the public. Utilities are required by law to serve any customer who is willing to pay for service. In addition, the service provided must be safe. In the United States, utilities are regulated by commissions, primarily at the state and federal levels.

By law, utilities also have certain rights. For example, each is entitled to rates that cover its operating costs and yield a reasonable profit. If the profit is not high enough, the company will be unable to attract investors and maintain and expand its services to customers.

In the United States, federal commissions regulate utilities that provide services across state boundaries. For example, the Federal Energy Regulatory Commission regulates natural gas and oil pipelines and hydroelectric power plants. The Federal Communications Commission controls broadcasting as well as telephone and telegraph services. The Securities and Exchange Commission regulates the finances of companies that control electric power and natural gas utilities.

Other federal regulatory commissions in the United States include the Federal Aviation Administration, which establishes the rules that all planes must follow when flying in the United States; and the Nuclear Regulatory Commission, which regulates the production of nuclear energy. All 50 states, plus the District of Columbia, also have their own regulatory commissions.

History. Public utilities in the modern sense can be traced to early English *common law.* Common law designated certain activities as "peculiarly affected with the public interest." Included were activities of docks, inns, warehouses, ferries, and canal companies. At first, these activities were regulated by court decision only. Later, they were also regulated by legislation.

The Interstate Commerce Commission became the first U.S. government commission with regulatory powers in 1887. It regulated the rates and trade practices of companies that transported goods and people by train and, eventually, those that handled transport by motor vehicle and boat. By 1920, more than two-thirds of the U.S. states had set up regulatory commissions. Many federal utility commissions were set up after 1930.

Developments in the late 1960's and the 1970's forced many public utilities in the United States to struggle for financial survival. During those years, interest rates, fuel prices, and construction and other costs rose sharply. As a result, public utilities found it necessary to increase their rates by large percentages. In addition, the increased construction costs led to a slowdown in the building of new facilities and thus prevented some utilities from providing adequate levels of service. Rates for electricity also rose because new federal regulations required electric power plants to install millions of dollars worth of pollution control equipment. Pressures by the public, by commercial and industrial groups, and by the federal government to limit utility rate increases in time helped lead to financial problems for many utilities. The financial position of utilities also worsened because of a new emphasis on conservation.

By the mid-1970's, many people in the United States had come to believe that public utilities could operate more efficiently if they were subject to less regulation. As a result, Congress began to significantly reduce regulation. Legislation passed in 1976 and 1980 granted railroad companies greater freedom in pricing and in abandoning unprofitable services. The Airline Deregulation Act of 1978 phased out federal control of fares and routes in the passenger airline industry. The Motor Carrier Act of 1980 increased competition in the trucking industry by allowing trucking firms greater freedom in setting rates. Deregulation in the natural gas industry led to the elimination by 1990 of price controls on all natural gas sold in the United States. Beginning in the 1980's, lower inflation and moderate fuel prices led to an improved financial position for most public utilities.

In the telephone industry, competition increased in 1984, when a federal lawsuit forced AT&T to give up its local telephone companies. At the time, AT&T dominated both local and long-distance telephone service in the United States. By the late 1990's, some states had begun taking steps to allow for increased competition among providers of electric power. Charles F. Phillips, Jr.

Publicity. See Advertising; Motion picture (Distribution); Public relations.

Publishing is the process of preparing, manufacturing, and distributing books, magazines, newspapers, or other materials in printed or electronic form. This article describes book publishing. For information on magazine and newspaper publishing, see **Magazine** and **Newspaper**.

Book publishing is a relatively small industry. But beyond its size, publishing has enormous importance in the educational and cultural life of society. Books are a living record of human history and knowledge. They have been the basic means of passing along the essential data of civilization from generation to generation. In addition, books provide pleasure and relaxation for many people.

The person or group who directs the business of publishing a book is called the *publisher.* A publisher is responsible for obtaining and editing the manuscript of the author or authors. The publisher supervises the printing and binding of the manuscript, and distributes it to the public. Most of the work is performed in a company called a *publishing house.* A publishing house may have hundreds of employees working in large office buildings, or it may consist of only one person who does all the work in a single room.

People have made and sold books since ancient times. For a description of the development of book publishing, see **Book** (History).

Kinds of book publishing

Publishing can be divided into three areas, each based on a specific type of book. The areas are generally known as (1) trade books, (2) educational books, and (3) reference books.

Trade books are books intended for the general reader. These books include novels; picture books for children; biographies; books on current affairs, history, or psychology; travel guides; cookbooks; and "do-it-yourself" books.

Trade publishers distribute most of their books through bookstores and the book departments of other stores. Some trade publishers also distribute books through *book clubs,* which people join to get certain selected books, usually at reduced prices.

Educational books are published by special publishers or by educational departments of trade publishers. These books are the textbooks used for instruction in schools and colleges. Educational publishers often employ teachers and educators to plan and write their textbooks. To keep information in classrooms current, educational publishers regularly produce updated editions of the textbook. Educational publishers sell some of their books directly to buyers in school systems. In addition, these publishers distribute their books through college bookstores.

Educational publishing is probably the most profitable area of book publishing. A great number of teachers and students are required to buy certain textbooks for their classes. A successful textbook can sell millions of copies over many years. Many publishers use the profits from educational books to publish trade books that may have uncertain sales prospects.

Reference books include encyclopedias, dictionaries, almanacs, and similar books that contain information about a wide variety of topics. The material is organized so that the user can find facts quickly and easily. Most reference book publishers hire specialists to serve either as authors for the topics or as consultants for general areas of knowledge.

The production of reference books can be expensive, especially if the works consist of several volumes. But many of these books have large sales to libraries, where people go to look up information. Reference books are also sold to individuals and families who want to have sources of information readily available. Some reference publishers use sales representatives who demonstrate and sell the books in the home.

Since the early 1990's, an increasing amount of reference material has been published in electronic form. This *electronic publishing* involves storing a large volume of information on a *CD-ROM* (*C*ompact *D*isc *R*ead-*O*nly *M*emory) or other device. The information can then be accessed quickly using a computer. It may also include such *multimedia* features as sound and video clips. Some publishers make certain materials available on the Internet, the global computer network.

Publishing a book

An author's manuscript goes through several stages of preparation before it reaches the reader in book form. Most publishers follow the same basic steps.

Acquiring the manuscript. Some authors of manuscripts hire *literary agents* to represent them. An agent first tries to find a suitable publisher for the manuscript. The agent then helps negotiate the author's financial arrangements with the publisher. In addition, some agents make deals allowing parts or all of the book to appear in magazines or as television or motion-picture adaptations. For these services, the author pays the agent 10 to 15 percent of the author's income from the book.

Most publishing houses employ editors who have the responsibility of acquiring manuscripts for publication. They will watch for likely subjects and authors, and negotiate the purchase with both authors and agents. They discuss the terms by which the company will produce and market the book.

The publisher signs a written contract with the author specifying the *advance* and *royalties.* An advance is a sum of money that the publisher, in effect, loans to the author while the book is in preparation. The advance is subtracted from the royalties, which are payments that the publisher makes to the author from profits gained from the sale of the book. The publisher pays the author a certain percentage of the price of the book for each copy sold. The contract also names a date for publication.

Editing the manuscript. After obtaining the manuscript, the editor prepares it for publication. Editing is the process of putting the author's writing into "publishable" form. The editor looks for parts of the manuscript that call for clarification or reorganization. Spelling, grammar, punctuation, and other elements of style may need to be corrected or altered. Some publishers also have policies or guidelines for the length, organization, and content of their books. The editor may have to verify the accuracy of certain facts in the manuscript. Editing may mean adding or omitting parts, or even rewriting the entire manuscript.

Some publishers divide the editing responsibilities among several people. For example, one editor obtains the manuscript and clarifies its content. Another person may edit it for proper style. Someone else may research all the facts.

Designing and printing. After the manuscript has been edited, it is ready for the designer. The designer is responsible for the overall appearance of the book, including the cover. An attractive book cover can arouse a person's interest in buying the book. In addition, the designer may develop illustrations to accompany the text, including photographs, drawings, charts, and diagrams. For most books, either a designer at the publishing house or a specially hired artist provides the illustrations and cover design. The designer blends the artwork with the edited text in an organized, readable way. In many cases, the designer will work with the author, editor, and other people involved in preparing the book for publication.

After the designer completes his or her work, the book is ready for film output and printing. The edited manuscript is flowed into a page layout. Then the publisher sends the book in electronic form, either on a removable storage device or over a computer network, to a company called a *service bureau.* The service bureau produces images of the book's pages on film and sample copies of each page called *proofs.* The editors, proofreaders, and designers then review the proofs. The author may also check the proofs and revise the material. The bureau produces new film and proofs based on corrections made by the publisher's staff. When the proofs require no further corrections, the film is sent to a printer for use in making printing plates and producing the book.

A book may be *hardbound* or *softbound.* Most hardbound books have covers made of cloth, plastic, or leather over cardboard. Softbound books, also called *paperbacks,* have paper covers. Some books are made first in hardbound and later reprinted as paperbacks. Other books are published only as paperbacks. Normally, paperback books cost less than hardbound books.

Marketing the book. Plans for advertising and distributing begin long before the book comes off the presses. Researchers in the sales department try to estimate the potential readership for the book. Sales representatives collect orders from bookstores and libraries to determine how many copies the printer should produce in time for the official date of publication. Accountants estimate the amount of money that the publisher should spend on advertising and promoting the book.

Publishers use various ways to advertise a book. Publicity specialists may schedule interviews for the author in newspapers and magazines and on television and radio shows. They also send proofs of the book to selected book reviewers in hopes that favorable reviews will reach the public near the date of the book's publication.

As part of their advertising strategy, trade publishers may give advance copies of a book to political figures, television celebrities, or other influential personalities who might praise the book to the public. The publisher may also send the author on tours of bookstores to autograph copies for customers. The publisher watches the progress of sales to determine if and when to order another *printing* (new copies) from the printer.

Careers in publishing

A publishing career appeals to many young people because it involves working in a literary field, sometimes with famous people. The book publishing industry has numerous kinds of jobs. There are positions for writing, editing, illustrating, designing, advertising, selling, research, management, and administration.

A person pursuing a career in book publishing should first choose a general type of work, such as editing or selling. Good writing skills and a background in liberal arts or journalism should help prepare a person for an entry-level editorial position. Most young people begin as editorial assistants and hope to be promoted in time to full editor. A job may require special qualifications based on the material published. For example, many educational publishers require editors to have experience in teaching. Experience working in bookstores may provide a good background for people who wish to go into sales. Interesting careers are also open in promotion and publicity. Some people find employment through agencies that specialize in publishing job placement. Most of these agencies are located in major publishing centers, such as London and New York City.

Many people who wish to publish books start their own businesses. Some begin as *book packagers* who design, research, supply illustrations, and hire writers to create finished books—usually highly illustrated ones—to sell directly to a publisher. The publisher then serves as a distributor for those books. John F. Baker

Puccini, *poo CHEE nee,* **Giacomo,** *JAH koh moh* (1858-1924), was an Italian opera composer. He ranks as one of the greatest opera composers of all time. Audiences can hear such Puccini operas as *La Bohème* (1896), *Tosca* (1900), *Madama Butterfly* (1904), *The Girl of the Golden West* (1910), and *Turandot* (first performed in 1926, after Puccini's death). Opera companies also present *Il Trittico* (1918), a collection of three one-act operas—*Il Tabarro, Suor Angelica,* and *Gianni Schicchi.*

© Hulton Archive

Giacomo Puccini

Puccini was born on Dec. 23, 1858, in Lucca, the fourth generation of a family of professional musicians. After studying music—unwillingly at first—Puccini became a church organist. Receiving a grant from Queen Margherita, the young Puccini enrolled at the Milan Conservatory in 1880. He submitted his first

opera, the one-act *Le Villi,* in a competition, but did not win. However, the opera was produced successfully in Milan in 1884. His second opera, *Edgar* (1889), was less well received.

With the triumph of *Manon Lescaut* (1893), Puccini began to gain a reputation as the probable successor to the aging Verdi. All 10 of the Puccini operas that followed won international fame for their mastery of theatrical effect, their emotionally charged melodies, and their orchestral brilliance. Puccini was a perfectionist who was concerned with every detail of his operas. His works are tightly written and always delighted his audiences. Of his works composed after 1893, only *La Rondine* (1917), which is almost a musical comedy, has lost popularity. Puccini was working on the last scene of *Turandot* when he died in Brussels, Belgium. The opera was completed by the Italian composer Franco Alfano.

Charles H. Webb

Puck, or Robin Goodfellow, a mischievous spirit or elf in English folklore, tormented people, usually in fun. He was also called Hobgoblin, and in 1595, Edmund Spenser, in one of his poems, included *the Pouke* among evil spirits. In *A Midsummer Night's Dream,* William Shakespeare presented him as a good-hearted elf. Enjoying his pranks on human beings, Puck exclaimed, "Lord, what fools these mortals be!" Puck figures prominently in Rudyard Kipling's *Puck of Pook's Hill* and *Rewards and Fairies.* Ellen J. Stekert

Water color (1785) by William Blake; Tate Gallery, London (Bridgeman Art Library)

Puck, *third from left,* was one of the main characters in William Shakespeare's romantic comedy *A Midsummer Night's Dream.* This painting shows Puck dancing for Oberon and Titania, the king and queen of the fairies, *left.*

Pudding stone is a term for a type of *conglomerate stone* consisting of rounded pebbles embedded in a fine-grained *matrix* (cementing material). It is a term used chiefly in the United Kingdom. Finley C. Bishop

Puebla, *PWEHB luh* or *pyoo EHB luh,* is a state in east-central Mexico between Mexico City and the Gulf of Mexico (see **Mexico** [political map]). Puebla has a population of 5,070,346 and an area of 13,090 square miles (33,902 square kilometers). Mexico's three highest mountains, Pico de Orizaba (Citlaltépetl), Popocatépetl, and Ixtacihuatl, stand on Puebla's borders. Puebla farmers grow barley, corn, green peppers, peanuts, potatoes, rice, sugar cane, and wheat. Puebla also produces apples, plums, and other fruits. It is also a textile center. The city of Puebla is the capital. James D. Riley

Puebla, *PWEHB luh* or *pyoo EHB luh* (pop. 1,346,176), officially Puebla de Zaragoza, *day ZAR uh GOH zuh,* one of the largest cities in Mexico, stands 65 miles (105 kilometers) southeast of Mexico City. It is the capital of the state of Puebla. For location, see **Mexico** (political map). Puebla has many beautiful Spanish-style churches and other buildings. The city's chief products include cotton textiles, glass, fine pottery, and beautifully colored tiles. Founded in 1531, Puebla is one of the oldest Spanish settlements in Mexico. Roderic A. Camp

Pueblo, *PWEHB loh* (pop. 102,121; met. area pop. 141,472), is one of the largest cities in Colorado. It serves as the cultural, educational, and industrial center for the southeastern part of the state. Pueblo lies at the junction of the Arkansas River and Fountain Creek. For the city's location, see **Colorado** (political map).

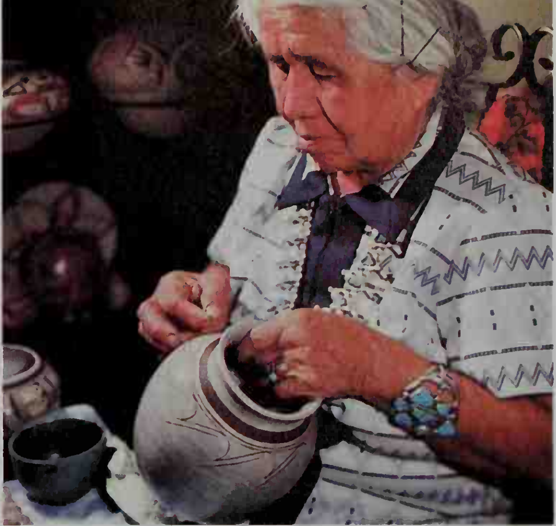
Pueblo's industries include the manufacture of air conditioners, airliner brake pads, bricks and tiles, and steel. Rocky Mountain Steel Mills (formerly CF&I Steel Corporation) is the city's oldest and largest employer. The steel plant began operations in 1881. Pueblo is the home of the University of Southern Colorado and the Sangre de Cristo Arts and Conference Center. Since 1872, the city has hosted the annual Colorado State Fair, held in August.

Arapaho, Cheyenne, and Ute Indians lived in eastern Colorado when Europeans first came to the area. In 1840, trappers built Fort Pueblo on the site of what is now Pueblo. The Ute killed the fort's inhabitants in 1854. Gold prospectors settled on the site in 1858 and named their community Fountain City. It was incorporated as the city of Pueblo in 1860.

In the 1970's, Pueblo began a downtown modernization program. The Pueblo Mall opened in 1976. The Pueblo Convention Center opened in 1997. It includes meeting and exhibit space, and a large ballroom. An eight-story hotel, at the convention center, opened in 1998. Pueblo has a council-manager government. It is the county seat of Pueblo County. Leonard W. Gregory

For monthly weather, see **Colorado** (Climate).

Pueblo Indians, *PWEHB loh,* are a people who live in villages in New Mexico and Arizona. The Pueblo belong to many communities, each of which speaks one of six languages. These Indians were named in the 1500's by Spanish explorers. The Spaniards found them living in villages that resembled Spanish towns, and the word *pueblo* means *town* in Spanish. The Spaniards used the word to refer to both the people and their villages.



Most of the 53,000 Pueblo live in 19 villages in New Mexico. The majority live along the Rio Grande, in areas between Taos and Albuquerque. Others live in deserts or high plateau areas called *mesas* in Laguna and Acoma in west-central New Mexico. This article discusses the Indians who live in the 19 villages. Other Pueblo include the Zuni of western New Mexico and the Hopi of northeastern Arizona (see **Hopi Indians; Zuni Indians**).

Each Pueblo village has its own government and organization, but the Pueblo people remain linked to one another because of similar customs. The Pueblo have strong ties to their traditions and homeland. They have lived in the same location longer than any other people of the United States or Canada.

Jerry D. Jacka

A Pueblo village of today looks much like the Pueblo towns of centuries ago. The Pueblo have traditionally lived in stone or adobe structures that resemble apartment buildings.

Pottery Treasures, © 1976 by Graphic Arts Center Publishing Co. (Jerry D. Jacka)

Colorful pottery is created by people in all Pueblo villages. The pottery of each village has its own special designs. This Pueblo woman is painting a handmade jar.

Early life. The Pueblo are descendants of a people known as the *Anasazi,* a name given them by the Navajo Indians. The Anasazi began to build homes of many stories about A.D. 700. Between A.D. 1000 and 1300, Pueblo culture developed greatly in northern Arizona, northern New Mexico, southern Colorado, and southern Utah. By 1300, many Pueblo had moved south to the fertile valleys of the Rio Grande and its branches.

Some Pueblo Indians built villages in the valleys, and others lived in desert and mountain areas. Desert surrounded many of the valleys, and the people set up irrigation systems so they could grow crops. Pueblo women gathered berries and other foods, and the men hunted game.

Pueblo villages consisted of stone or adobe structures that resembled apartment buildings. These homes had as many as four stories, and the Indians used ladders to reach the upper levels. Some families of grandparents, parents, children, aunts, and uncles lived in two or more connected dwellings.

The villages were governed by religious leaders. The Pueblo held many religious ceremonials to promote harmony and order in the universe. They believed that if harmony and order in the universe were maintained, the spirits would ensure abundant game and provide sufficient rain for their crops. Pueblo men performed *kachina dances,* in which they represented spirits of the earth, sky, and water. The dancers wore masks that symbolized the spirits. Most pueblos had underground chambers called *kivas* that were used for ceremonies and meetings.

The Pueblo designed excellent pottery. They also wove beautiful baskets and cotton for their clothing.

Contact with other peoples. In 1598, the Spaniards established a settlement near a Pueblo village. They forced the Pueblo to work for them and to give them some of their crops. The Spaniards also forced the Indians to follow Roman Catholic ways. The Pueblo pretended to accept Catholicism, but they secretly continued their own religious practices.

In 1680, the Pueblo leader Popé led his people in a revolt that ended Spanish rule. The Indians remained free until 1692, when the Spaniards again gained control. In return for yielding control, the Pueblo demanded an end to forced labor and to interference in their internal affairs, particularly their religion.

From 1821 to 1846, Mexico ruled the Pueblo lands. The United States gained the territory from Mexico as a result of the Mexican War (1846-1848). In the Treaty of Guadalupe Hidalgo of 1848, the United States agreed to uphold the Pueblo's title to their lands, which had been recognized by both the Spanish and the Mexican governments.

Through the years, the Pueblo have sought greater economic and political rights. In 1970, for example, the pueblo of Taos won title to Blue Lake, a sacred lake to the Indians of Taos. The government had made it part of a national forest.

The Pueblo today follow many of the traditions that their ancestors established centuries ago. Most Pueblo have accepted modern ways only if such changes seem necessary or practical.

Most Pueblo practice their ancient religion, though some observe certain Catholic customs. Religious officials and nonreligious officials appointed by them govern 13 of the New Mexico villages. The people of the other 5 villages elect their officials.

The majority of Pueblo live in homes that have only one story. Most of them work in nearby cities and towns, and many have professional careers. The Pueblo also make baskets, jewelry, pottery, and weavings and sell almost all their crafts. Alfonso Ortiz

San Juan is Puerto Rico's capital and largest city. Modern hotels and condominiums line the city's shore. Puerto Rico's warm climate, sandy beaches, and scenic and historic sites attract many tourists. Puerto Rico is a commonwealth of the United States.

Puerto Rico

Puerto Rico, *PWAIR tuh REE koh* or *PAWR tuh REE koh,* is a beautiful, fertile island about 1,000 miles (1,600 kilometers) southeast of Florida. It forms part of the boundary between the Atlantic Ocean and the Caribbean Sea. The pleasant climate, sandy beaches, and resort hotels attract a large number of tourists from the United States mainland. Puerto Rico is a possession of the United States, with commonwealth status. Its official name is Commonwealth of Puerto Rico.

Puerto Ricans are U.S. citizens, and can move to the mainland without immigration restrictions. But when living on the island, they cannot vote in presidential elections and do not pay federal income taxes. The commonwealth receives assistance and protection from the U.S. government. But the Puerto Rican government has authority in many local matters.

Puerto Rico is the only part of what is now the United States where Christopher Columbus landed. Columbus reached the island in 1493 and claimed it for Spain. He named the island San Juan Bautista (St. John the Baptist). Spain surrendered the island to the United States in 1898 at the end of the Spanish-American War.

The name *Puerto Rico* means *rich port* in Spanish. In

The contributor of this article is Fernando Bayrón-Toro, Professor of Political Sciences at the University of Puerto Rico, Mayagüez.

Facts in brief

Capital: San Juan.
Government: *Congress*—Resident commissioner, who votes only in committees. *Commonwealth legislature*—senators, 28; representatives, 54. *Local government*—78 municipalities.
Area: 3,515 mi² (9,103 km²), including Culebra, Mona, and Vieques islands and 56 mi² (145 km²) of inland water. *Greatest distances*—east-west, 111 mi (179 km); north-south, 39 mi (63 km). *Coastline*—311 mi (501 km).
Elevation: *Highest*—Cerro de Punta, 4,389 ft (1,338 m) above sea level. *Lowest*—sea level along the coast.
Population: *2000 census*—3,808,610; density, 1,084 per mi² (418 per km²); distribution, 67 percent urban, 33 percent rural.
Chief products: *Agriculture*—milk, poultry and eggs, beef cattle, coffee. *Fishing industry*—lobsters. *Manufacturing*—pharmaceuticals, food products, electrical equipment, machinery, scientific instruments, clothing.
Became a commonwealth: July 25, 1952.
Commonwealth abbreviations: P.R. (traditional); PR (postal).
Commonwealth motto: *Joannes est nomen ejus* (John Is His Name).
Commonwealth anthem: "La Borinqueña." Music by Felix Astol y Artés.

Odyssey Productions

The Cordillera Central, a mountain range, stretches across south-central Puerto Rico. The island's highest peak, Cerro de Punta, rises 4,389 feet (1,338 meters) in the range. This mountain region also has fertile valleys, where farmers grow coffee and many kinds of citrus fruits.

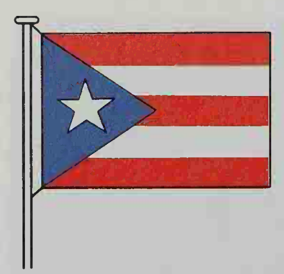
early colonial days, it was the name for San Juan, Puerto Rico's capital and largest city. The name gradually came to be used for the entire island.

Puerto Rico's Spanish heritage is reflected in the language and customs of its people. Spanish is the main language and one of the two official languages of Puerto Rico. Many Puerto Ricans also speak English, the other official language. The people celebrate religious holidays with colorful festivals. Churches and forts from Spanish colonial days still stand on the island.

Puerto Rico also reflects its ties with the United States. The island's large cities have freeways, housing projects, and shopping centers like those in many cities on the U.S. mainland.

Government

Puerto Rico is a commonwealth of the United States. The U.S. Congress is responsible for governing Puerto Rico, but the island exercises self-government in all local affairs. Most federal laws apply to Puerto Rico as though it were a state. A resident commissioner, elected to a four-year term, represents Puerto Rico in Congress. The resident commissioner may vote in committees of the House of Representatives, but may not vote on final legislation in the House.



Commonwealth government operates under its own Constitution, adopted in 1952. The governor is the chief executive officer and appoints other top executive officials. The governor is elected to a four-year term and may serve an unlimited number of terms.

The legislature of Puerto Rico consists of a senate and a house of representatives. Members of both houses

WORLD BOOK map

Puerto Rico lies between the Atlantic Ocean and the Caribbean Sea. It is southeast of the mainland of the United States.

Symbols of Puerto Rico. The flag was designed about 1895 and was officially adopted in 1952. On the seal, the lamb symbolizes peace and brotherhood. The letters *F* and *I* stand for King Ferdinand and Queen Isabella of Spain.

serve four-year terms. Puerto Rico has 8 senatorial districts and 40 representative districts. Voters in each senatorial district elect 2 senators, and voters in each representative district elect 1 representative. Voters also elect 11 senators and 11 representatives *at-large*—that is, from the entire commonwealth, rather than from districts. If one political party controls more than two-thirds of the seats of either house, the minority parties get extra senators at-large or representatives at-large.

The legislature meets in regular session from January through May and during September and October. The governor may call special sessions at any time.

Courts. The Supreme Court is the highest court in Puerto Rico. It has seven justices appointed by the governor. The justices may serve until they reach the retirement age of 70. The Circuit Court of Appeals consists of 33 judges, each appointed by the governor to 16-year terms. Puerto Rico's 210 superior court judges are appointed to 12-year terms. The 105 municipal judges are appointed to 8-year terms. Cases involving federal law are heard in the U.S. District Court for Puerto Rico, which has seven judges appointed by the U.S. president.

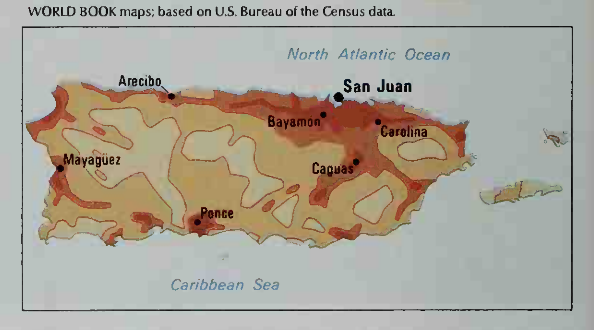
Local government. Puerto Rico's basic unit of local government is the *municipio* (municipality). The commonwealth is divided into 78 municipalities. The voters in each municipality elect a mayor and an assembly. The mayor appoints a secretary-auditor and a treasurer.

© Ray Ellis, Photo Researchers

Puerto Rico's capitol, in San Juan, was first used in 1929. San Juan has been the capital since 1521. The first capital, established in 1508, was Caparra, across the bay from San Juan.

Politics. Political parties that get at least 5 percent of the vote cast in elections receive financial aid from a government fund. Puerto Rico's two leading parties are the New Progressive Party, which wants Puerto Rico to become a U.S. state; and the Popular Democratic Party, which favors continuing the island's commonwealth status. A third party is the Independence Party, which favors independence for the island.

People



Puerto Rico is a crowded island. It has a population density of about 1,000 persons per square mile (400 per

Population density

Puerto Rico is a densely populated island. About two-thirds of the island's people live in urban areas. The San Juan area is Puerto Rico's most heavily populated region.

Persons per sq. mi.	Persons per km^2
More than 1,000	More than 400
750 to 1,000	300 to 400
500 to 750	200 to 300
Less than 500	Less than 200

WORLD BOOK maps; based on U.S. Bureau of the Census data.

square kilometer), which is greater than the density of any U.S. state. The 2000 United States census reported that Puerto Rico had 3,808,610 people. The island's population had increased 8 percent over the 1990 figure, 3,522,037.

More than four-fifths of all Puerto Ricans live within the metropolitan areas of Aquadilla, Arecibo, Caguas, Mayagüez, Ponce, and San Juan (see **Metropolitan area**). For the populations of these metropolitan areas, see the *Index* to the political map of Puerto Rico.

San Juan, Puerto Rico's capital and largest city, is a seaport on the north coast. The San Juan metropolitan area includes Bayamón and Carolina, the next largest cities. Ponce, the fourth largest city, is a commercial and cultural center on the south coast. Other major cities of Puerto Rico include Caguas, the largest inland city; Guaynabo, near San Juan; and Mayagüez, on the west coast.

The first inhabitants of Puerto Rico were the Arawak Indians. Most of them were killed or died of disease after the Spanish settlers came. No full-blooded Indians are now known to live in Puerto Rico. But some Puerto Ricans are descended from Indians who intermarried with Spanish settlers. Beginning in 1510, blacks were

Traditional wood figures, called *santos,* are carved by craftworkers known as *santeros.* Most santos represent a saint or a religious scene. This santero has made several Nativity figures.

David R. Frazier Photolibrary

A game of dominoes occupies the leisure time of these men. Most Puerto Ricans have Spanish ancestors. Others include people of black African, Portuguese, Italian, and French descent.

brought from Africa to work on the plantations and in the small gold mines. Today, their descendants live chiefly in the lowlands near the coast.

By far the largest part of the population is of Spanish descent. There are also Portuguese, Italians, and French. About 85 percent of the people are Roman Catholics, and most of the rest are Protestants.

Education

About 90 percent of Puerto Rico's people can read and write. The island has a public school system similar to those in the states. Puerto Rico's public school system has about 39,000 teachers and 765,000 students. About 150,000 students attend private schools. Spanish is the main language used in schools, but students are also taught English.

Visitor's guide

Beaches lined with palm trees surround Puerto Rico's interior of rugged mountain ranges and rolling hills. The island offers a variety of water sports. Many visitors enjoy the historic buildings and colorful shops in the older part of San Juan, called Old San Juan, and in the island's cultural center, Ponce. United States citizens do not need passports to travel to Puerto Rico.

Universities and colleges

This table lists the universities and colleges in Puerto Rico that grant bachelor's or advanced degrees and are accredited by the Middle States Association of Colleges and Schools.

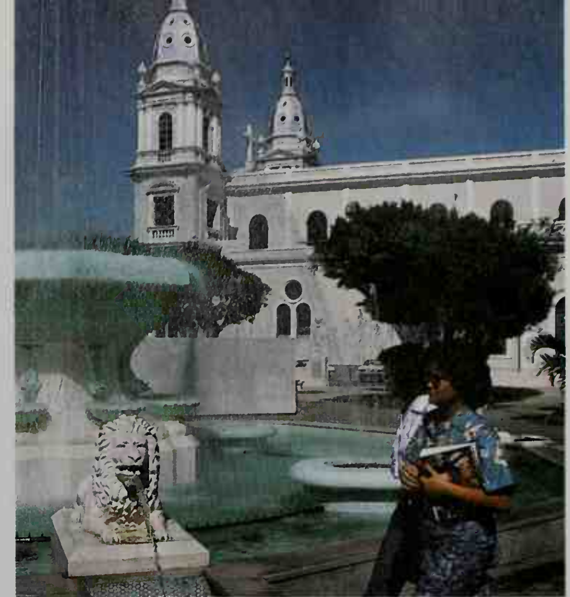
Places to visit

Following are brief descriptions of some of Puerto Rico's many interesting places to visit:



El Morro Fortress was built by the Spaniards between 1539 and 1787 to guard the Bay of San Juan.

El Yunque, "the anvil," is a mountain with a rain forest on its slopes. The El Yunque rain forest is part of the Caribbean National Forest and is the only rain forest in the U.S. Forest Service. The forest has about 240 species of trees and flowers.

Hacienda Buena Vista, in Ponce, is a restored coffee and grain mill from the 1800's. It includes rare turbine machinery and period furnishings.

Ponce Art Museum has the Caribbean's most extensive art collection. Its collection ranges from works by European old masters to those of modern artists.

Rio Camuy Cave Park, near Arecibo, has spectacular limestone caves carved thousands of years ago by one of the world's largest underground rivers.

Annual events

One of Puerto Rico's leading events is the Casals Festival, held in San Juan in mid-June. International musicians take part in orchestra and chamber music performances to honor the famed Spanish cellist Pablo Casals, whose mother was born in Puerto Rico.

Puerto Ricans have many interesting holidays and customs. Three Kings' Day, January 6, marks the end of the Christmas season. Puerto Rican children receive gifts on that day, as well as at Christmas. Each town has a patron saint, and each celebrates its saint's day with a festival. Other annual events in Puerto Rico include:

January-March: Birthday of Puerto Rican educator and essayist Eugenio Maria de Hostos (January 11); Carnival in Ponce (February); Coffee Harvest Festival in Maricao (February); Orange Festival in Las Marías (February); Dulce Sueño Paso Fino Horse Show in Guayama (late February to early March); Heineken Regatta, first leg of the Caribbean Ocean Racing Triangle (March); Emancipation Day, marking abolition of slavery in 1873 (March 22).

April -June: Birthday of Jose de Diego, a Puerto Rican patriot (April 16); Heineken Jazz Festival in San Juan (May); Bomba y Plena Festival, an Afro-Caribbean music and dance festival in Ponce (June); Aibonito Flower Festival (June); Eve of San Juan Bautista Day (June 23).

July-September: Barranquitas Artisans Fair (mid-July); Commonwealth Day (July 25); Loiza Festival, a folk and religious festival honoring St. James the apostle (late July); International Billfish Tournament in San Juan (August-September); Inter-American Festival of the Arts in San Juan (September-October).

October-December: Columbus Day (October 12); Jayuya Indian Festival (November); Discovery Day, honoring Columbus's 1493 sighting of Puerto Rico (November 19); Hatillo Festival of the Masks (late December).

Dancers in traditional costumes perform folk dances in Old San Juan. Puerto Ricans celebrate many holidays with colorful festivals that feature traditional music and dancing.

The land

Puerto Rico is one of the largest islands that lie between Florida and South America. It covers 3,515 square miles (9,103 square kilometers). Puerto Rico includes many smaller islands. The largest, in order of size, are Vieques, Mona, and Culebra.

Land regions. Puerto Rico has four main land regions. They are (1) the Coastal Lowlands, (2) the Coastal Valleys, (3) the Foothills, and (4) the Central Mountains.

The Coastal Lowlands border the coast on the north and the south. The northern lowlands are about 8 to 12 miles (13 to 19 kilometers) wide. Their climate is generally humid.

The southern lowlands cover a narrower area, and have a much drier climate. Most of Puerto Rico's industry and its largest cities, San Juan, Bayamón, Ponce, and Carolina, are in the lowlands.

The Coastal Valleys extend inland from the coast on the east and the west. Most of the land in these valleys is used for sugar cane. Coconuts and other fruits also grow in these areas.

The Foothills rise in two long east-west chains, just inland from the northern and southern coastal lowlands. Much of the area has jagged peaks and round basins. The basins formed when water wore away the limestone under the hills, and the ground sank.

The Central Mountains run east and west across the south-central part of the island. The main range is the Cordillera Central. The highest peak in Puerto Rico,

Odyssey Productions

The Coastal Lowlands border Puerto Rico's coast on the north and the south. Farmland in the northern lowlands, near Arecibo, is shown here. Farmland covers more than half of Puerto Rico's total land area.

Chip and Rosa Maria Peterson

The Coastal Valleys extend inland from the east and west coasts. The scene at the left is in the east. Much sugar cane is grown in the Coastal Valleys.

Cerro de Punta, rises 4,389 feet (1,338 meters) in the Cordillera Central. This mountain region also contains many fertile valleys, in which farmers raise crops. Coffee is the main crop of the western part of the region. Citrus fruits are also grown in the mountain valleys.

Coastline. Puerto Rico's general coastline measures 311 miles (501 kilometers). The tidal shoreline, which includes small bays and inlets, is about 700 miles (1,127 kilometers) long. The island has many beaches and harbors.

Rivers. Puerto Rico's longest rivers, such as the Arecibo, flow northward from the mountains into the Atlantic Ocean. None of the rivers can be used by large boats. But they are important sources of water for hydroelectric power, industries, and irrigation.

Plant and animal life. Much of the tropical forest that formerly covered Puerto Rico is gone. Many of the remaining trees are valued for their beauty. These include the *flamboyan* (poinciana), with flaming red blossoms; the African tulip; and the huge *ceiba* (kapok). Some trees bear delicious fruits and nuts that are little known elsewhere in the United States. Among these are breadfruit, guanábanas, papayas, sea grapes, and star apples.

Many beautiful flowers grow on the island. They include orchids and poinsettias.

Puerto Rico has few wild animals. Bats and mongooses are found on the island. Puerto Rico has few snakes of any kind and no poisonous ones. However, it has iguanas and other lizards. It also has many kinds of birds. The coquí (a small frog) sounds a clear, musical note during the evening hours. The island's many insects include the cucubano, a large tropical relative of the common firefly. Some insects, such as mole crickets and termites, may damage buildings and crops. The Puerto Rico Paso Fino Horse, famous for its delicate way of walking, is bred on the island.

Fishes in the ocean around Puerto Rico include barracuda, herring, marlin, mullet, pompano, sharks, snappers, Spanish mackerel, and tuna. Lobsters and oysters are also caught in Puerto Rican waters.

Odyssey Productions

A tropical rain forest on El Yunque mountain, *above,* may receive more than 200 inches (510 centimeters) of rain a year. The area makes up part of the Caribbean National Forest.

Climate

Puerto Rico's pleasant climate makes the island a popular vacation spot. The climate also provides good conditions for growing crops. Temperatures average about 73° F. (23° C) in January and 80° F. (27° C) in July. Frost and snow never occur, and even hail is rare. Sea breezes make the climate much more comfortable in summer than it is in the central United States.

In many parts of the island, some rain falls nearly every day. The rainfall is usually heavy, but it lasts only a short time. The drier sections of the southern coast average 37 inches (94 centimeters) of rain a year. Rainfall in the north averages 70 inches (180 centimeters) a year. A rain forest on El Yunque, a mountain, sometimes gets over 200 inches (510 centimeters) a year.

People in Puerto Rico must be alert for hurricanes from June through November. But severe hurricanes occur only once every 10 years, on the average. These storms are predicted hours or even days in advance by the National Weather Service. The storm warnings are announced by newspapers, radio, and television so that people have time to take shelter in strong buildings.

The highest temperature ever recorded in Puerto

Average yearly precipitation

This map shows the average amount of rain and other moisture that Puerto Rico receives in a year. In many parts of the island, some rain falls nearly every day.

Rico, 103 °F (39 °C), occurred at San Lorenzo on Aug. 22, 1906. The lowest temperature, 40 °F (4 °C), was recorded at Aibonito on March 9, 1911.

Economy

Manufacturing is the single most valuable industry in Puerto Rico. It provides a larger portion of the *gross domestic product* than any other economic activity. Gross domestic product is the total value of all goods and services produced within a region in a year. The service industries, taken together, supply more than half of the gross domestic product of Puerto Rico.

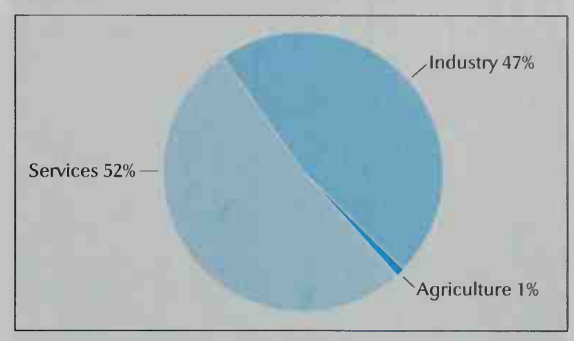
Millions of tourists visit Puerto Rico every year. Most of them come from the United States mainland. Tourist activities benefit many parts of Puerto Rico's economy, especially such services as the operation of hotels and restaurants.

Natural resources. One of Puerto Rico's most important natural resources is its climate. The year-round balmy weather not only attracts many tourists but also helps make Puerto Rico a desirable location for industries. The warm, moist climate also allows Puerto Ricans to grow tropical crops.

Soil is an important resource in Puerto Rico. The island has more than 400 types of soil. Soil erosion is a serious problem on the island, but it is being reduced by soil conservation methods such as contour planting.

Minerals. Clays, limestone, salt, sand and gravel, and stone account for almost all of Puerto Rico's mine production. Spanish settlers washed gold out of Puerto Rican streams, but the gold supply was soon used up. Small deposits of cobalt and nickel and two large copper deposits have been found on the island. Salt is made from seawater.

Service industries, taken together, make up the largest portion of the gross domestic product of Puerto Rico. Most of the service industries are concentrated in the metropolitan areas.



Both (1) wholesale and retail trade and (2) finance, insurance, and real estate lead the service industries of Puerto Rico in terms of contributions to the gross do-

Pharmaceutical manufacturing is an important economic activity in Puerto Rico. These workers are packaging medicinal drugs at a pharmaceutical factory near San Juan.

Puerto Rico's gross domestic product

The gross domestic product (GDP) is the total value of goods and services produced in a region in a year, minus income sent or received from abroad. The GDP can be used to compare the economic performances of countries and regions. Puerto Rico's GDP was $59,900,000,000 in 1999.

Production and workers by economic activities

Economic activities	Percent of GDP produced	Employed workers: Number of people	Employed workers: Percent of total
Manufacturing	44	159,000	14
Wholesale & retail trade	13	229,000	20
Finance, insurance, & real estate	13	43,000	4
Community, business, & personal services	10	306,000	27
Government	9	246,000	21
Transportation, communication, & utilities	7	59,000	5
Construction & mining	3	78,000	7
Agriculture	1	27,000	2
Total	100	1,147,000	100

Figures are for 1999.
Sources: GDP data, Puerto Rico Planning Board; employment data, *World Book* estimates based on data from Puerto Rico Department of Labor.

mestic product. The wholesale trade of clothing, medicine, and sugar is especially important. San Juan, Bayamón, and Ponce are the leading centers of wholesale trade. Puerto Rico's retail trade is aided by tourist spending at shops and restaurants.

Rapidly growing cities make real estate especially important in Puerto Rico. San Juan is the chief financial center, home to hundreds of banks and other financial organizations.

Taken together, (1) community, business, and personal services and (2) government services employ nearly half of all Puerto Ricans. Community, business, and personal services include private health care and tourism. Government services include military activities and the operation of public schools and hospitals.

Information on transportation, communication, and utilities appears later in this section.

Manufacturing. Products manufactured and processed in the commonwealth have a *value added by manufacture* of about $26 billion a year. This figure represents the increase in value of raw materials after they become finished products.

About 2,000 factories operate in Puerto Rico. Many were set up under the *Operation Bootstrap* program for

Odyssey Productions

Pineapple harvesters pick pineapples and then put them on a conveyor belt that carries the fruit to a truck. Puerto Rico produces many varieties of fruits.

Bottles of rum line a conveyor belt at a plant near Cataño. These people are checking the bottles before packaging. Puerto Rico exports large quantities of rum each year.

economic development. The commonwealth government helped the owners of the factories find locations, finance construction, and train workers.

Factories in Puerto Rico manufacture and process a great variety of products. Leading manufactured products include chemicals—especially pharmaceuticals—food products, electrical equipment, machinery, medical and scientific instruments, and clothing. Other important manufactured products of Puerto Rico include rubber and plastic products; stone, clay, and glass products; fabricated metals; printed materials; leather and leather products; and tobacco products. *Centrales* (sugar mills) in Puerto Rico produce raw sugar from the sugar cane grown on the island.

Agriculture. About 40 percent of Puerto Rico's total land area is suitable for farming. Much fertilizer must be used to enrich the fields, because the land has been worked hard for hundreds of years. Irrigation provides water for farms located in the drier southern parts of the island. Irrigation is also used on farms along the northwest coast of Puerto Rico.

Milk, poultry, and eggs are Puerto Rico's most valuable livestock products. Farmers also raise beef cattle. Puerto Rico has rapidly increased its production of livestock to help feed its growing city populations.

Coffee is the leading crop in Puerto Rico. Coffee beans are grown in the western part of the central mountains. Nearly half of Puerto Rico's farmworkers are employed in coffee farming.

Bananas are Puerto Rico's most important commercial fruit. Pineapples are grown in the coastal lowlands, especially in the north. Other fruits grown in Puerto Rico include avocados, coconuts, oranges and other citrus fruits, and plantains. Sugar cane is grown in the coastal lowlands of the island.

Mining. Stone, sand and gravel, and lime rank as Puerto Rico's most valuable mined products. Other mined products include clays and salt.

Fishing industry. Puerto Rico has an annual fish catch valued at about $21 million. About 11 million pounds (5 million kilograms) of fish and shellfish are caught yearly. Lobster is the most valuable catch.

Trade between Puerto Rico and the United States is governed by the same laws and regulations as trade between the states of the United States. Puerto Ricans do not pay customs duties on imports from the United

Economy of Puerto Rico

This map shows the major uses of land in Puerto Rico. It also shows where the leading farm, fishing, and mineral products are produced. Manufacturing is Puerto Rico's single most important economic activity. The island's chief manufacturing centers are shown in red on the map.

WORLD BOOK map

States, as they do on imports from other countries.

In the past, Puerto Rico's most important exports were sugar, molasses, and rum. Of these, only rum is still exported in large quantities. Today, Puerto Rico also exports pharmaceuticals, computer and electronic products, refined petroleum products, medical and scientific instruments, metal products, leather products, clothing, and tobacco products. Puerto Rico's chief imports are chemicals, crude petroleum, electrical machinery, food products, and transportation equipment.

San Juan, Ponce, and Mayagüez have *foreign trade zones* where owners can process, store, and reship their goods without paying customs duties. See **Free trade zone.**

Electric power is produced and sold on the island by the Puerto Rico Electric Power Authority, a public corporation created in 1941. Electric power is produced by power plants that burn petroleum, and also in small amounts by hydroelectric plants.

Transportation. Puerto Rico has over 14,000 miles (22,500 kilometers) of surfaced roads. These roads provide good transportation by automobile, bus, and truck throughout the island.

Puerto Rico's three chief seaports are San Juan in the north, Ponce in the south, and Mayagüez in the west. The largest airport is Luis Muñoz Marín International Airport in San Juan.

Communication. Puerto Rico's first newspaper, *El Día,* was founded at Ponce in 1909. Today, chief newspapers include *El Nuevo Día, El Vocero,* and the *San Juan Star,* all of which are published in San Juan. Mayagüez's *La Estella de Puerto Rico* is also a leading paper.

Puerto Rico's first radio station, WKAQ, began broadcasting from San Juan in 1922. WKAQ built Puerto Rico's first television station in 1954 in San Juan. Today, the commonwealth has about 120 radio stations and about 25 television stations. Many of the island's households receive cable television service. Most cable programming is broadcast in English.

History

Spanish rule. Christopher Columbus sailed to Puerto Rico in 1493 on his second voyage to the Western Hemisphere. Spaniards, led by Juan Ponce de León, began the first European settlement on the island in 1508. Ponce de León became the first governor in 1509. The Borinquen, or Arawak, Indians who lived there rose against the settlers, but all the revolts failed. By the mid-1500's, most of the Indians had been killed or enslaved, or had died of disease.

The island colony suffered for hundreds of years from hurricanes and plagues. It was attacked by the Carib Indians, who lived on nearby islands, and by the Dutch, English, and French. Still, the Spanish population slowly grew, fortifications and towns were built, and agriculture increased. After about 1850, the desire for greater freedom from Spain grew among Puerto Rico's people. In 1897, Spain provided for a large amount of local rule, and a new Puerto Rican government was set up in 1898 shortly before the start of the Spanish-American War.

United States rule. On July 25, 1898, U.S. forces began to land in Puerto Rico after bombarding San Juan. Spain surrendered Puerto Rico to the United States in the Treaty of Paris, which was signed on Dec. 10, 1898.

Granger Collection

Juan Ponce de León, a Spanish explorer, sailed to Puerto Rico in 1508 and established the first European settlement there. He became the first governor of the island in 1509.

Under the temporary U.S. military government, the use of U.S. money and postage stamps on the island was made official. The first U.S. civil governor was appointed by President William McKinley under the terms of the Organic Act of 1900, known as the Foraker Act.

The United States built dams, hospitals, roads, and schools. But the economy depended on agriculture, and U.S. firms owned and received much of the profits from the best plantations and largest sugar mills.

In 1917, the second Organic Act, or Jones Act, gave U.S. citizenship to Puerto Ricans. The island contributed troops to the U.S. armed forces in World War I (1914-1918) and World War II (1939-1945). During the Korean War (1950-1953), the U.S. Army's 65th Infantry Regiment, made up of Puerto Ricans, won fame for its courage and daring. Puerto Rican soldiers also participated in the Vietnam War (1957-1975) and the Persian Gulf War (1991).

Building a democracy. In the early 1940's, Puerto Rican leaders, with aid from the United States, began a program to improve living conditions on the island. The program became known as Operation Bootstrap. Large farms were broken up, and land was redistributed among farmworkers. An improved educational program rapidly reduced the number of Puerto Ricans who could not read and write. Thousands of old slum dwellings were torn down and replaced by modern housing.

On July 25, 1946, President Harry S. Truman appointed Jesús Toribio Piñero the first island-born governor of Puerto Rico. In 1947, Congress expanded Puerto Rican

Puerto Rico became a U.S. commonwealth on July 25, 1952. A flag-raising ceremony, *shown here,* celebrated the occasion.

UPI/Bettmann Newsphotos

self-government by permitting the islanders to elect their own governor. Luis Muñoz Marín was elected governor in 1948. His Popular Democratic Party favored a commonwealth linked to the United States.

In 1950, Congress passed Public Law 600, which gave Puerto Rico the power to write its own constitution. Puerto Ricans approved the law in a referendum vote in 1951. A Puerto Rican convention then wrote a constitution modeled on that of the United States, and the Puerto Rican people approved it. The U.S. Congress approved the constitution on July 1, 1952, and on July 25 Puerto Rico became a self-governing commonwealth.

During the 1950's, a sharp rise occurred in Puerto Rican migration to the U.S. mainland. Thousands of islanders moved to New York City and other large mainland cities in search of jobs. Many could not speak English and had difficulty adjusting to their new life.

Puerto Rico today continues to benefit from rapid industrial growth during the 1960's and 1970's. The Economic Development Administration, known in Spanish as *Fomento,* has helped businesses establish thousands of factories. Industrial growth has reduced unemployment. But the unemployment rate is still about three times as high as the U.S. rate. Puerto Rico also stresses cultural development, through government-sponsored events and organizations, such as the annual Casals Festival of music and the Institute of Puerto Rican Culture.

In 1964, Governor Muñoz Marín announced he would not run for a fifth term. Another Popular Democrat, Roberto Sánchez Vilella, became governor in 1965.

In 1967, Puerto Ricans voted to retain their commonwealth status rather than to become a U.S. state or an independent country. In 1968, Luis A. Ferré of the New Progressive Party was elected governor. Ferré and his party favored statehood for Puerto Rico. He ran for reelection in 1972 and was defeated by Rafael Hernández Colón, the Popular Democratic Party candidate.

Carlos Romero Barceló of the New Progressive Party was elected governor in 1976 and was reelected in 1980. In 1984, he was defeated by Hernández Colón. Hernández Colón was reelected in 1988. In 1992, Pedro J. Rosselló of the New Progressive Party was elected governor. He was reelected in 1996. The New Progressive Party was defeated by the Popular Democrats in 2000, when Sila Maria Calderon was elected the first woman governor of Puerto Rico.

Important dates in Puerto Rico

1493 Christopher Columbus sailed to Puerto Rico during his second voyage to the Western Hemisphere.

1508 Spanish colonists began settlement of Puerto Rico.

1598 The English seized San Juan and held it for five months.

1625 The Dutch burned San Juan.

1797 The English attacked San Juan.

1898 U.S. troops occupied Puerto Rico, and Spain ceded the island to the U.S. after the Spanish-American War.

1900 Congress established civil government for Puerto Rico with the first Organic Act, or Foraker Act.

1917 Puerto Ricans became citizens of the United States by the second Organic Act, or Jones Act.

1947 Congress amended the Jones Act to permit Puerto Ricans to elect their own governor.

1949 Luis Muñoz Marín was inaugurated as the first elected governor of Puerto Rico. He served until 1965.

1952 Puerto Rico adopted its constitution and became a commonwealth.

1967-1998 Puerto Rico held three referendums that resulted in the island keeping its commonwealth status.

2000 Sila Maria Calderon was elected the first woman governor of Puerto Rico.

In 1993 and 1998, Puerto Rico held referendums on whether it should remain a commonwealth. Both votes resulted in the island keeping its commonwealth status.

In September 1998, Hurricane Georges swept across Puerto Rico. This powerful storm killed three people and caused about $2 billion in damage.

Since 1941, the U.S. Navy has conducted military training activities, including bombing exercises, on the Puerto Rican island of Vieques. Many Puerto Ricans oppose the Navy's presence on Vieques and have demanded an end to the military exercises. The protests became particularly intense after a civilian security guard was killed in a bombing accident in April 1999. From then to May 2000, protesters occupied the Navy bombing range, forcing a suspension of the bombing. Exercises resumed in June 2000. Fernando Bayrón-Toro

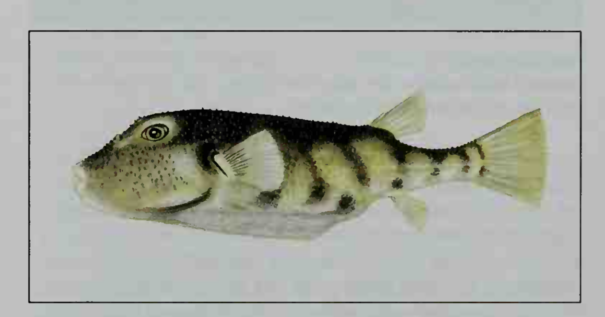
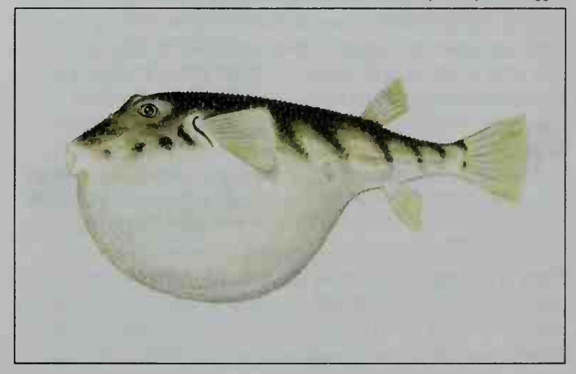
Puff adder. See Adder.



Puffball is the name of a group of fungi that produce ball- or pear-shaped fruit with completely enclosed spores. Many puffballs have white flesh. They are edible until the developing spores begin to color the flesh. When a puffball is mature, the inside is a mass of powdery, yellowish, purplish, or olive-colored spores. Sometimes an opening, or crater, develops in the top of a puffball. Clouds of tiny spores that look like puffs of smoke may come out through the opening when the fruit is touched or squeezed. For this reason, one kind of puffball is called the *devil's snuffbox.* Joe F. Ammirati

Scientific classification. Most puffballs belong to the puffball family, Lycoperdaceae.

Puffer is a type of fish that can inflate its body like a balloon. Puffers normally measure from 2 inches (5 centimeters) to nearly 2 feet (60 centimeters) in length. These fish can greatly expand their stomachs and take on the shape of a ball by rapidly swallowing water or air. Puffers frequently inflate their bodies to protect themselves from their enemies.



There are about 120 kinds of puffers. They have greatly modified scales and many have smooth, leathery skin. Some puffers have prickles on their underside that appear only when the fish inflates its body. Certain small puffers have a long, narrow snout. All puffers have strong upper and lower teeth that form a beak. Puffers use their teeth to tear coral or crush the shells of various sea animals. Puffers eat shellfish, such as clams, crabs, and shrimp.

Most puffers live in warm oceans. A few varieties are

The puffer becomes twice its normal size and floats on the surface of the water when it inflates its stomach.

WORLD BOOK illustrations of a northern puffer by John F. Eggert

found in rivers and other fresh water. Some puffers can be eaten, but most are poisonous. In Japan, puffer is known as *fugu* and considered a rare and tasty dish. Some puffers do well in home aquariums.

Leighton R. Taylor, Jr.

Scientific classification. Puffers belong to the family Tetraodontidae.

Puffin, also called *sea parrot,* is an odd-looking bird that lives in the Arctic waters of the Atlantic and Pacific oceans. It has a thick body, a large head, and a high, flattened bill. The three major species of puffins are the *Atlantic puffin,* the *horned puffin,* and the *tufted puffin.*

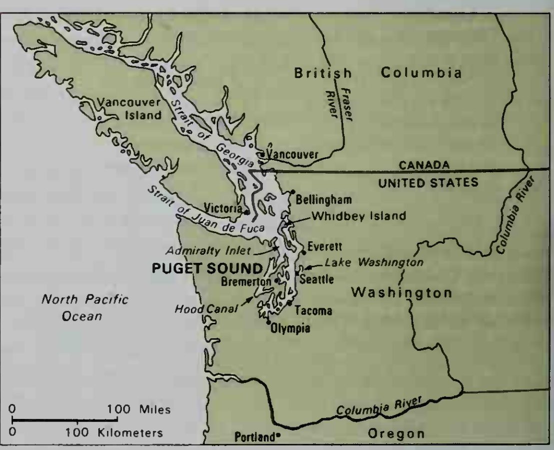
© Jeff Lepore, Photo Researchers

Horned puffins spend the summer on the Pacific coasts of Alaska and Russia, where they raise their young. The rest of the year, they live in the North Pacific Ocean.

During the breeding season, colored growths form on the male puffin's beak. Atlantic and horned puffins have white feathers on the breast, throat, underparts, and sides of the head. They have blackish feathers on the wings, tail, and forepart of the neck. The tufted puffin is dark underneath, with a white-streaked plume on the side of the head.

Puffins feed chiefly on fish. They are expert swimmers and divers and come to land mainly in June and July, during the breeding season. Puffins make their nests in large colonies on rocky coasts and islands. The female lays one white egg in a burrow or crevice in the rocks. The chick stays in the burrow for 7 to 8 weeks after hatching. The chick then emerges and learns how to feed on its own. Donald F. Bruning

Scientific classification. Puffins belong to the auk family, Alcidae. The scientific name for the Atlantic puffin is *Fratercula arctica.* The horned puffin is *F. corniculata,* and the tufted puffin is *Lunda cirrhata.*



Pug is a small dog with a short nose and a tail that curls tightly over its back. It is the largest of the toy-sized dogs and weighs 14 to 18 pounds (6.4 to 8 kilograms). It has short, smooth hair and a deeply wrinkled face. It originated in China. See also **Dog** (picture: Toy dogs); **Toy dog.** Critically reviewed by the American Kennel Club

Puget, *PYOO jiht,* **Peter** (1762?-1822), a British naval officer and explorer, played an important part in the exploration of the north Pacific Coast of North America. Puget Sound, in the state of Washington, Cape Puget in Alaska, and Puget Island in the Columbia River were named for him. From 1791 to 1795, Puget sailed as a lieutenant with Captain George Vancouver on a four-year trip around the world. This voyage included a trip to Nootka Sound, near what is now Vancouver Island, to regain English territory from Spain. In 1792, they became the first Europeans to reach the sound, or arm, of the Pacific Ocean that Vancouver named for Puget. Puget explored the sound, surveyed the Yakutat Bay area on the southern Alaska coast, and helped explore Cook Inlet and Prince William Sound in the Gulf of Alaska. Barry M. Gough

See also **Vancouver, George.**

Puget Sound, *PYOO jiht,* is a large, irregular inlet in the northwest corner of the state of Washington. Puget Sound is a leading American shipping center. The ports of Seattle, Tacoma, Bremerton, Olympia, and Everett stand on its banks. The sound is 100 miles (160 kilometers) long, and covers an area of about 2,000 square miles (5,200 square kilometers). The largest ships can steam into any part of the sound, as its depth is from 180 to 925 feet (55 to 282 meters).

The Strait of Juan de Fuca links Puget Sound and the Pacific Ocean. From the meeting point of this strait and the Strait of Georgia, Puget Sound extends southward for about 35 miles (56 kilometers) before it divides into two main branches—Admiralty Inlet and the Hood Canal. The Lake Washington Ship Canal extends from Puget Sound to Lake Washington at Seattle.

WORLD BOOK map

Location of Puget Sound

Most of the sound's shores are high and wooded. Whidbey Island, one of the many islands in Puget Sound, is more than 40 miles (64 kilometers) long. Whidbey Island is one of the largest United States islands.

The sound is noted for the fisheries and lumber mills along its shores. Fish packing and canning are among the area's chief industries. The sound is the center of Washington's great lumber industry. Jois C. Child

Pulaski, *pu LAS kee,* **Casimir,** *KAZ uh mir* (1747?-1779), a Polish nobleman and soldier, won fame for his role with the Continental Army in the Revolutionary War in America (1775-1783). He sailed to America in 1777 to offer his services to General George Washington. Pulaski was Washington's aide-de-camp at the Battle of Brandywine in September 1777. At Washington's urging, Congress made Pulaski a brigadier general. Pulaski, an expert cavalryman, organized a corps of cavalrymen that became known as Pulaski's Legion. The group performed valiantly in the South. It participated in the siege of Savannah, where Pulaski was wounded on Oct. 9, 1779. He died two days later.

Brown Bros.

Casimir Pulaski

Before coming to America, Pulaski led an unsuccessful revolt of Polish forces against Russia, which controlled Poland at that time. He learned of the American cause in France from Benjamin Franklin, who encouraged him to travel to America.

Pulaski was born in the province of Podolia, Poland, now part of Ukraine. By an act of the United States Congress, October 11 is observed as Pulaski Day. In Illinois, the first Monday in March is celebrated as Pulaski Day.

James Kirby Martin

Puli, *POO lee,* is a medium-sized sheepdog originally bred in Hungary. The puli's coat is black, rust-colored and black, white, or gray and becomes tangled into ropelike cords if allowed to grow naturally. The dog is intelligent and fun-loving. It makes an excellent pet and watchdog. The puli stands about 17 inches (43 centimeters) tall at the shoulder.

Critically reviewed by the Puli Club of America

See also **Dog** (picture: Some breeds of dogs have unusual characteristics).

Pulitzer, *PUL iht suhr* or *PYOO liht suhr,* **Joseph** (1847-1911), was a Hungarian immigrant who became one of the greatest American newspaper publishers in history. He established the Pulitzer Prizes for achievements in journalism, literature, music, and art (see **Pulitzer Prizes**).

Pulitzer was born in Mako, Hungary. His family moved to Budapest when he was young. He left home at 17 in search of military adventure, but the armed forces of Austria, Britain, and France rejected him because of his poor health and bad eyesight. A recruiter enlisted Pulitzer to fight with the Union Army in the American Civil War. After brief service, he settled in St. Louis, Missouri, became a U.S. citizen, and worked as a laborer.

His career. In 1868, Pulitzer became a reporter on a German-language newspaper in St. Louis. Within four years, he became managing editor and part owner of the paper. He won a seat in the Missouri House of Representatives in 1869. Pulitzer became a leader among the people of German descent in St. Louis and helped Horace Greeley in his 1872 presidential campaign. But three years later, Pulitzer became a Democrat and sold his interest in the newspaper, which was Republican.

In 1876 and 1877, Pulitzer served as a correspondent in Washington, D.C., for the *New York Sun.* He bought two newspapers, the *St. Louis Dispatch* and *Evening Post,* in 1878, and combined them into the *St. Louis Post-Dispatch.* Within four years, the *St. Louis Post-Dispatch* made him a fortune.

In 1883, Pulitzer bought the *New York World,* a financially troubled New York City paper. He soon transformed the *World* into a vigorous, crusading newspaper with the largest circulation in the nation, 250,000 by 1887. This paper was one of the first to use the color comics and sensationalism that gave rise to "yellow journalism" (see **Journalism** [The age of sensationalism]).

Pulitzer was almost totally blind after 1887, and also extremely sensitive to noise. From then until his death, he directed the *World* and the *Post-Dispatch* from his home with the help of secretaries.

His bequests. Pulitzer left $2 million to establish a graduate school of journalism at Columbia University. The Pulitzer Prizes were created with part of this money. He left $500,000 each to the New York Philharmonic Society and to the Metropolitan Museum of Art. Pulitzer's will also provided that the *World* should never be sold. But a court permitted the sale of the newspaper in 1931 because of financial losses. The family kept the *Post-Dispatch.*

Michael Emery

Pulitzer Prizes, *PUL iht suhr* or *PYOO liht suhr,* are awards given in the United States each year for distinguished achievement in journalism, literature, drama, and music. The prizes were established by Joseph Pulitzer, a newspaper publisher who was the founder of the *St. Louis Post-Dispatch.*

Pulitzer's will provided $2 million for Columbia University to establish a graduate school of journalism. Pulitzer specified that after the school had operated for at least three years, prizes should be awarded for the advancement of education, journalism, literature, music, public morals, and public service. The Columbia University School of Journalism was founded in 1912, and the first Pulitzer Prizes were awarded in 1917.

Prizes in journalism are awarded for material appearing in a United States newspaper published daily, Sunday, or at least once a week during the calendar year. Prizes are awarded in 14 categories. Two runners-up are also announced in each category. In all cases, preference is given to work first appearing in newspapers, and characterized by high quality of writing and reporting.

(1) For a distinguished example of meritorious public-service by a newspaper through the use of its journalistic resources, which may include cartoons, editorials, photographs, or reporting. The prize in this category is a gold medal.

(2) For a distinguished example of breaking news reporting. The prize is $7,500.

(3) For a distinguished example of investigative reporting within a newspaper's area of circulation by an individual or a team, published as a single article or a series. The prize is $7,500.

(4) For explanatory journalism that illuminates significant and complex issues. The prize is $7,500.

(5) For a distinguished example of beat reporting. The prize is $7,500.

(6) For a distinguished example of reporting on nation-

al affairs. The prize is $7,500.

(7) For a distinguished example of reporting on international affairs, including United Nations correspondence. The prize is $7,500.

(8) For a distinguished example of feature writing giving prime consideration to high literary quality and originality. The prize is $7,500.

(9) For distinguished commentary. The prize is $7,500.

(10) For distinguished criticism. The prize is $7,500.

(11) For distinguished editorial writing. Consideration is given to clarity of style, moral purpose, sound reasoning, and power to influence public opinion in what the writer feels is the right direction. All the editorial writer's work during the year is taken into account. The prize is $7,500.

(12) For a distinguished example of a cartoonist's work. The cartoon should express an idea clearly, show good drawing and striking pictorial effect, and be intended to help some worthy cause of public importance. Consideration is given to all the artist's work during the year. The prize is $7,500.

(13) For an outstanding example of spot news photography in black and white or in color. An entry may consist of a photograph or photographs, a sequence, or an album. The prize is $7,500.

(14) For an outstanding example of feature photography in black and white or in color. An entry may consist of a photograph or photographs, a sequence, or an album. The prize is $7,500.

Prizes in literature, drama, and music. Awards in literature are made for works published during the calendar year. Awards for drama and music cover the 12 months from March 15 to March 14. Prizes are awarded in seven categories. Two runners-up are also announced in each category.

(1) For distinguished fiction published in book form by an American author, preferably dealing with American life. The prize is $7,500.

(2) For a distinguished play by an American author, preferably original in its source and dealing with American life. The prize is $7,500.

(3) For a distinguished book on the history of the United States. The prize is $7,500.

(4) For a distinguished biography or autobiography by an American author. The prize is $7,500.

(5) For a distinguished book of verse by an American author. The prize is $7,500.

(6) For a distinguished book of nonfiction by an American author, giving prime consideration to high literary quality and originality. The prize is $7,500.

(7) For a distinguished composition by an American in chamber, orchestral, or choral music; or for an opera or ballet. The work must have had its first American performance during the 12-month period under consideration. The prize is $7,500.

Special citations are sometimes awarded to honor a single achievement or an entire career. Both individuals and organizations have received citations.

Award procedures. Anyone may recommend a work for a Pulitzer Prize by writing to the Pulitzer Prize Office, 709 Journalism, Columbia University, New York, NY 10027. Entries for literature prizes must be made on or before November 1 of the year under consideration. Four copies of each work must be submitted.

Entries for journalism prizes must be made on or before February 1 following the year for which the work is being judged. Each entry must be accompanied by an exhibit in scrapbook form of news stories, editorials, photographs, or cartoons as published. The exhibit must be accompanied by the name and date of the paper and reasons why the work is being recommended. Except under special circumstances, exhibits in the public service category and both photography categories are limited to 20 articles or pictures. In feature writing, the limit is 5 articles. In the remaining journalism categories, the limit is 10 articles, editorials, or cartoons.

Pulitzer Prizes are awarded annually in April by Columbia University on the recommendation of the Pulitzer Prize Board. There are 16 voting members on the board. The permanent members are the president of Columbia University and Joseph Pulitzer, Jr., grandson of the founder of the prizes. The other members serve a maximum of three terms of three years each. A permanent administrator serves as secretary of the board. The board chooses each of its members.

With the approval of the board, Columbia University recommends juries to vote on entries in all categories. Jurors are appointed for one year at a time. Most journalism juries consist of five journalists. Most literature juries consist of three distinguished writers, critics, or academic authorities for each category. Most music juries are made up of composers and music critics. Each jury makes three nominations to the board. The nominations are listed in alphabetical order. The board may accept or reject the findings of any jury or make substitute recommendations.

No person may serve on a jury if he or she could benefit from the selection of a particular winner. Any board member having any interest in any jury nomination must leave the room while a vote on the award in that category is taken.

If the board feels that no nominated book, play, musical composition, or journalistic work is worth a prize, the prize may be withheld. Robin H. Kuzen

Pulley is a wheel over which a rope or belt is passed for the purpose of transmitting energy and doing work. The rim of the pulley is grooved when the pulley carries either a rope or a belt that has a V-shaped cross section. However, if the pulley is to carry a belt that has a flat cross section, the rim of the pulley is barrel-shaped. The flat belt rides on the highest part of the rim.

The simplest pulley is a grooved wheel on a fixed axle. A rope passing over this wheel is tied to the load to be lifted, and a pull is applied to the other end of the rope. This type of pulley gives no mechanical advantage of lift, but it changes the direction of the force applied to the load. This is important when the space directly under the load is hard to get at, as when the load is in a boat.

When the pulley is to carry a continuous turning motion, the two ends of the rope are laced together. A belt used in this way is usually manufactured as an unbroken circular unit. A second pulley, which is connected to the source of energy, transmits a steady rotation to the first pulley. If the driver pulley and the driven pulley are of the same size, the only advantage is a choice of directions from which the energy may come. If the pulleys are of different sizes, an advantage of either speed or force may be obtained. Crossing the rope or belt that runs between the two pulleys reverses the direction of turn of the driven pulley.

The second basic type of pulley is a *movable pulley.*

WORLD BOOK illustration by Sarah Woodward

A simple pulley is shown in Figure 1. Figure 2 shows a fixed pulley that merely changes the direction of the force applied to the load (L). It has a mechanical advantage of 1. Figure 3 is a movable pulley from which the load is suspended.

The load is attached to the axle of this pulley. One end of the rope that passes through the pulley is attached to a fixed support above the load. A pull is applied to the free end of the rope in the same direction the load is to move. The mechanical advantage of a movable pulley is 2. This means that the pull applied to the free end of the rope need be only half the weight of the load. The rope attached to the fixed support also carries half the weight of the load. James D. Chalupnik

Pullman, George Mortimer (1831-1897), was an American businessman remembered chiefly in connection with the railroad sleeping car. He came to control the business of railroad sleeping cars when trains were a major means of transportation in the United States.

Pullman was born in Brocton, New York. He became a cabinetmaker and then worked as a construction contractor. Moving to Chicago in 1855, he became interested in improving railroad sleeping cars. In 1858, he remodeled two coaches into sleeping cars for the Chicago & Alton Railroad. Pullman and a friend, Ben Field, then designed a more elaborate sleeping car which they named *Pioneer.* It entered service in 1865. The car was converted from day to night use by swinging down the upper berths, folding the seats to make them into lower berths, and separating the berths by curtains.

Pullman started the Pullman Palace Car Company (later called the Pullman Company) in 1867. This firm built, staffed, and operated sleeping cars on all major railroads. In 1868, Pullman introduced a dining car that had a kitchen. His firm introduced parlor cars in 1875 and the vestibule for direct connection between cars in 1887.

By 1899, Pullman possessed a virtual monopoly on the sleeping-car business in the United States. His manufacturing plant was in Pullman, Illinois, a town built and owned by the Pullman Company that is now part of Chicago. John H. White, Jr.

See also **Pullman Strike.**

Pullman Strike, also called the Chicago Strike, was a violent labor dispute that took place in 1894. The strike involved the Pullman Company, which manufactured railroad cars near Chicago, and the American Railway Union (ARU). The ARU was a group of railroad workers who were led by Eugene V. Debs. The strike began when employees of the Pullman Company refused to re-

turn to work, to protest a reduction in their wages. In sympathy with the employees, the ARU refused to haul railroad cars made by the company. A general railroad strike resulted.

The railroad strike interfered with mail trains. A federal court ordered leaders of the ARU to call off the strike but they refused. President Grover Cleveland sent federal troops to protect the mail and maintain law and order. When the troops arrived in the Chicago area, violence erupted and much railroad property was destroyed. Debs and other union leaders were then arrested for refusing to obey the court order. The government actions ended the strike. The settlement demonstrated the power of the U.S. government to intervene against strikes that threatened the public interest. David Brody

Pulp. See **Paper** (How paper is made; diagram); **Forest products** (Paper and paperboard).

Pulsar, *PUHL sahr,* is an object in space from which regular bursts of electromagnetic radiation are received on the earth. Most of this radiation is in the form of radio waves. Pulsars received their name from these highly regular pulses.

Scientists believe pulsars are rapidly spinning *neutron stars,* dense stars composed primarily of tightly packed neutrons, or perhaps of elementary particles called *quarks* (see **Neutron star**; **Quark**). An extremely powerful magnetic field surrounds the neutron star and rotates with it. This rapidly rotating magnetic field produces a strong electric field that rips electrons and protons from the star's surface. As these particles flow from the star, they emit energy in the form of a narrow beam of radio waves. The beam rotates as the star spins. Using a radio telescope, an astronomer can detect a pulse of radio waves each time the pulsar rotates and the beam sweeps past the earth.

On the average, radio pulsars spin at the rate of twice a second. All radio pulsars eventually lose energy and slow down. They do so in such a predictable manner that their pulses can be used to measure time.

The strong gravity of a pulsar can capture gases from a nearby companion star. These gases crash into the pulsar, creating hot spots that send out beams of X rays. X rays are like radio waves but have much shorter wavelengths. Some pulsars gain momentum and rotate faster as they capture gases from companion stars. These pulsars, called *millisecond pulsars,* rotate hundreds of times per second. Scientists believe many millisecond pulsars occur in high concentrations of stars known as *globular clusters.*

Astronomers study pulsars to determine the motions of objects at the centers of globular clusters and to learn about the matter between stars in the Milky Way. Astronomers also study how pulsars turn their enormous rotational energy into radio beams.

Radio pulsars were discovered in 1967 by British astronomers Jocelyn Bell (later Bell Burnell) and Antony Hewish at Cambridge University. In 1992, astronomer Alexander Wolszczan of Pennsylvania State University announced evidence that three planets are orbiting a pulsar called PSR B1257+12. The pulsar is in the constellation Virgo and is about 1,300 *light-years* from the earth. One light-year is the distance that light travels in one year—about 5.88 trillion miles (9.46 trillion kilometers).
Daniel R. Stinebring

Pulse is caused by a stretching of the arteries that takes place after each heartbeat. It can be felt by placing the fingers on the wrist above the thumb at a point over the *radial artery.* The pulse also can be felt by touching the temples where the *temporal artery* is located, and at other places in the body where an artery is near the surface.

Each heartbeat consists of a contraction of the muscles of the heart that propels the blood into the arterial system, followed by a period of relaxation during which the heart refills. As the heart contracts, the blood is pumped into the *aorta* and *pulmonary arteries.* The aorta, the largest artery in the body, carries the blood aerated in the lungs from the left side of the heart to the rest of the body. As the blood rushes into the aorta, its elastic walls are stretched and it expands to make room for the blood. As the blood moves on to enter the arteries that branch off from the aorta, the walls relax and it contracts to normal size. The walls of these arteries and of their branches also expand and contract as the blood passes through them. The expansion of these arteries causes the pulsation known as the *pulse.*

The pulse rate of children is faster, and that of old people often is slower than that of the average healthy adult. While pulse rates between 50 and 85 per minute are considered within normal limits, the normal rate for the average man is about 72. The pulse of the average woman is a little faster—76 to 80 per minute. The pulse rate of a newborn child may be as high as 140 per minute. The normal rate for a seven-year-old child is about 90 per minute. Slower pulse rates of from 50 to 65 per minute are not unusual in elderly people. But regardless of a person's age, the pulse and heart rhythm should be regular.

A doctor feels a patient's pulse to find out if the heart is beating normally. If the pulse is too fast, too slow, or irregular, the doctor examines the patient to diagnose the cause of the abnormal pulse. Dominick Sabatino

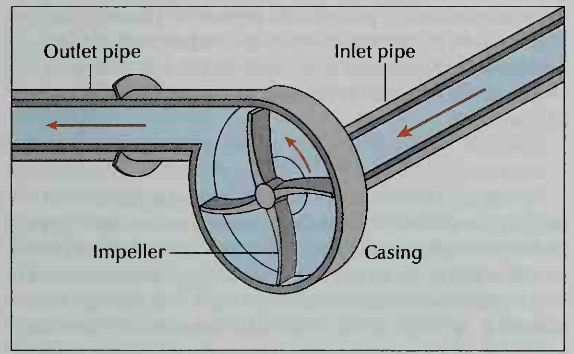
Puma. See **Mountain lion**.

Pumice, *PUM ihs,* is a grayish-white natural glass with many tiny holes. It is a valuable scouring, scrubbing, and polishing material in both powdered form and as pumice stone. Pumice forms when lava from a volcano flows onto the earth's surface or erupts violently into the air. The hot, gas-filled lava then cools quickly to form glass. Many tiny holes remain after the volcanic gases escape from the cooling lava. Marilyn M. Lindstrom

See also **Rock** (picture).



Pump is a device that moves liquids and gases. Pumps are used in a variety of machines and other devices, including home heating systems, refrigerators, oil wells and water wells, and turbojet and automobile engines. The fluids that are moved by pumps range from air for inflating bicycle tires to liquid sodium and liquid potassium used for cooling nuclear reactors. Most pumps are made of steel, but some of them are made of glass or plastic. Gas pumps are also called *compressors, fans,* or *blowers.*

There are two major types of pumps—*dynamic pumps* and *positive displacement pumps.* Dynamic pumps maintain a steady flow of fluid. Positive displace-

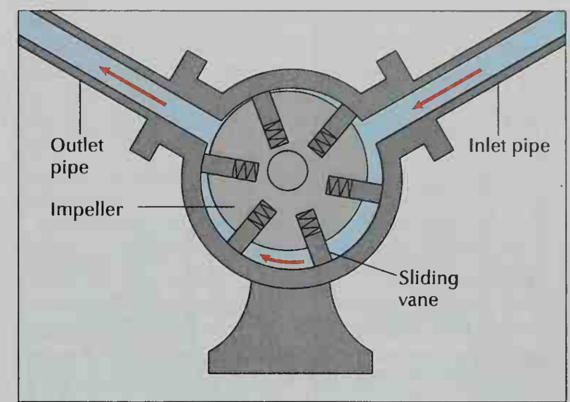
ment pumps, on the other hand, trap individual portions of fluid that are in an enclosed area before moving them along.

Dynamic pumps

Centrifugal pumps consist of a motor-driven propellerlike device, called an *impeller,* which is contained within a circular housing. The impeller is a wheel of curved blades that rotates on an axis. Before most centrifugal pumps can start pumping liquid, they must be *primed* (filled with liquid). As the impeller rotates, it creates suction that draws a continuous flow of fluid through an inlet pipe. Fluid enters the pump at the center of the impeller and travels out along the blades due to *centrifugal* (outward) force. The curved ends of the blades then sweep the fluid to an outlet port.

WORLD BOOK illustration by Mark Swindle

A centrifugal pump consists of a rotating device called an *impeller* within a circular casing. Fluid enters the pump near the center of the impeller, which sweeps it to an outlet pipe.



Centrifugal pumps are inexpensive and can handle large amounts of fluid. They are widely used in chemical-processing plants and oil refineries.

Axial-flow pumps have a motor-driven rotor that directs fluid along a path parallel to its axis. The fluid thus travels in a relatively straight path from the inlet pipe through the pump to the outlet pipe.

Axial-flow pumps are most often used as compressors in turbojet engines. Centrifugal pumps are sometimes used for this purpose, but axial-flow pumps are more efficient. Axial-flow compressors consist of alternating rows of rotors and stationary blades. The blades and rotors produce a pressure rise in the air as it moves through the axial-flow compressor. Air then leaves the compressor under high pressure. See **Jet propulsion** (Turbojet).

Jet pumps get their name from the way they move fluid. These pumps operate on the principle that a high-velocity fluid will carry along any other fluid it passes through. Most jet pumps send a jet of steam or water through the fluid that needs to be moved. The jet carries the fluid with it directly into the outlet pipe and, at the same time, creates a vacuum that draws more fluid into the pump. The amount of fluid that is carried out of most jet pumps is several times the amount of fluid that is in the jet itself.

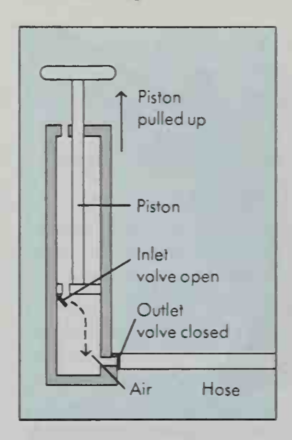
Jet pumps can be used to raise water from wells that are deeper than 200 feet (60 meters). In such cases, a centrifugal pump at ground level supplies water for a jet at the bottom of the well. The jet carries well water with it back up to ground level.

WORLD BOOK illustration by Mark Swindle

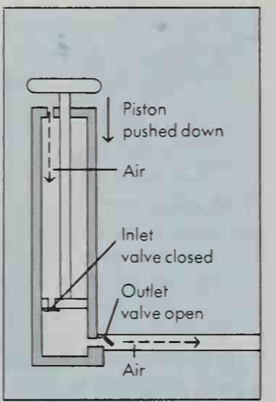
A sliding vane pump contains a slotted impeller. Sliding *vanes* (blades) are attached to the impeller by springs. They move in and out of the slots as the impeller rotates.

Jet pumps are also used in *high-vacuum diffusion pumps* to create a vacuum in an enclosed area. In high-vacuum diffusion pumps, a high-velocity jet of mercury or oil vapor is sent into the enclosed area. The vapor molecules collide with the molecules of air and force them out the outlet port.

Electromagnetic pumps are used chiefly to move liquid sodium and liquid potassium, which serve as coolants in nuclear reactors. Electromagnetic pumps consist of electrical conductors and magnetized pipes. The conductors send current through the fluid. This causes the fluid to become an electromagnet. The fluid is then moved by the magnetic attraction and *repulsion* (pushing away) between the fluid's magnetic field and the magnetic field of the pipes. The fluid is therefore moved in an electromagnetic pump in much the same way as an armature is moved in an electric motor (see **Electric motor**).



Positive displacement pumps



Rotary pumps are the most widely used positive displacement pumps. They are often used to pump such *viscous* (sticky) liquids as motor oil, syrup, and paint. There are three main types of rotary pumps. These types are: (1) gear pumps, (2) lobe pumps, and (3) sliding vane pumps.

Gear pumps consist of two gears that rotate against the walls of a circular housing. The inlet and outlet ports are at opposite sides of the housing, on line with the point where the teeth of the gears are fitted together. Fluid that enters the pump is trapped by the rotating gear teeth, which sweep the fluid along the pump wall to the outlet port.

Lobe pumps operate in a manner similar to gear pumps. However, instead of gears, lobe pumps are equipped with impellers that have *lobes* (rounded projections) fitted together. Lobe pumps can discharge large amounts of fluid at low pressure.

Sliding vane pumps consist of a slotted impeller mounted off-center in a circular housing. Sliding *vanes* (blades) move in and out of the slots. As the vanes rotate by the inlet port, they sweep up fluid and trap it against

WORLD BOOK illustrations by Arthur Grebetz

A bicycle tire pump has a piston that moves up and down. When the piston is raised, the air above it flows to the bottom of the pump. When it moves down, air is forced out the hose.

the pump wall. The distance between the impeller and the pump wall narrows near the outlet port. As the fluid is carried around to this port, the vanes are pushed in and the fluid is compressed. The pressurized fluid then rushes out the outlet port.

Reciprocating pumps consist of a piston that moves back and forth within a cylinder. One end of the cylinder has an opening through which the *connecting rod* of the piston passes. The other end of the cylinder, called the *closed end,* has an inlet valve or an outlet valve, or both valves, depending on the type of pump. In certain types of reciprocating pumps, the inlet valve or the outlet valve is located on the piston. Common reciprocating pumps include lift pumps, force pumps, and bicycle tire pumps.

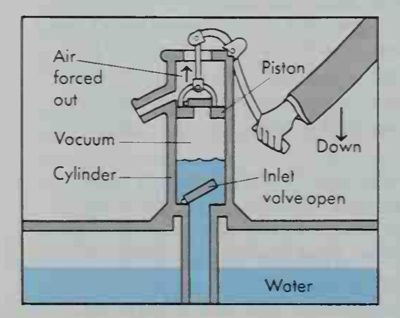
Lift pumps draw water from wells. In a lift pump, the inlet valve is at the closed end of the cylinder and the outlet valve is on the piston. As the piston is raised, water is drawn up through the inlet valve. As the piston moves down, the inlet valve closes, forcing water through the outlet valve and up above the piston. As the piston is raised again, the outlet valve closes and the water is lifted to an opening, where it leaves the pump. At the same time, more water is drawn through the inlet valve.

It is theoretically possible for a lift pump to raise water in a well almost 34 feet (10.4 meters). However, because of leakage and resistance, a lift pump cannot raise water that is deeper than about 25 feet (7.6 meters).

Force pumps are similar to lift pumps. However, in force pumps, both the inlet valve and the outlet valve are at the closed end of the cylinder. As the piston moves away from the closed end, fluid enters the cylinder. When the piston moves toward the closed end, the fluid is forced out the outlet valve.

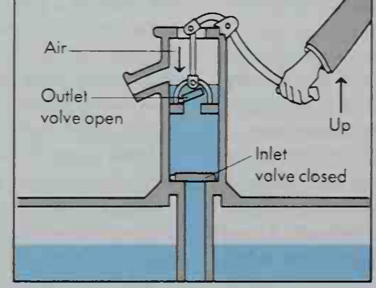
Bicycle tire pumps vary in the number and location of the valves they have and in the way air enters the cylinder. Some simple bicycle tire pumps have the inlet valve on the piston and the outlet valve is located at the closed end of the cylinder. Air enters the pump near the point where the connecting rod passes through the cylinder. As the rod is pulled out, air passes through the piston and fills the areas between the piston and the outlet valve. As the rod is pushed in, the inlet valve closes and the piston forces air through the outlet valve of the pump.

History



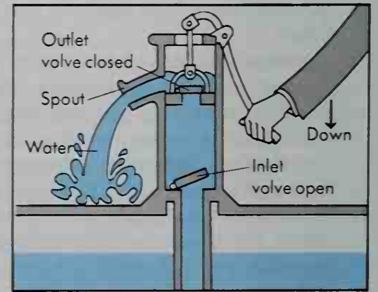
Pumping devices have been an important means of moving fluids for thousands of years. The ancient Egyptians used water wheels with buckets mounted on them to move water for irrigation. The buckets scooped water from wells and streams and deposited it in ditches that carried it to fields. In the 200's B.C., Ctesibius, a Greek inventor, made a reciprocating pump for pumping water. About the same time, Archimedes, a Greek mathematician, invented a screw pump that was made up of a screw rotating in a cylinder (see **Archimedean screw**). This type of pump was used to drain and to irrigate the Nile Valley.

True centrifugal pumps were not developed until the late 1600's, when Denis Papin, a French-born inventor, made one with straight vanes. The British inventor John G. Appold introduced a curved-vane centrifugal pump in 1851. Axial-flow compressors were first used on turbojet engines in the 1940's. Marian Visich, Jr.



See also **Milking machine; Well.**

Pumpkin is a vegetable related to squash. Pumpkin plants produce round or oval fruits, also called *pumpkins,* that have hard shells and coarse, stringy pulp. A



How a lift pump works Lift pumps are used to draw water from some wells. The outlet valve is on a piston, which moves up and down in the pump's cylinder. The inlet valve is at the closed end of the cylinder.

When the handle is pushed down, the piston rises and forces out air. Water enters the cylinder to replace the air.

Pulling up on the handle lowers the piston through the water. Force closes the inlet valve and opens the outlet valve.

WORLD BOOK illustrations by Arthur Grebetz

Pushing down on the handle raises the piston, and the water above the piston pours out the spout.

central cavity within the fruit holds the seeds. Most pumpkins weigh from 5 to 30 pounds (2.3 to 14 kilograms). However, some may weigh more than 1,000 pounds (450 kilograms). The majority of pumpkins are orange, but many pumpkins are white, yellow, or other colors.

Pumpkins are rich in vitamin A and potassium. People cook pumpkins in various ways, especially as pumpkin pie. Pumpkin seeds, a popular snack, provide protein and iron. Especially popular are the hull-less seeds that do not have a hard coat or outer shell. In the United States, people of all ages enjoy carving pumpkins into jack-o'-lanterns to celebrate Halloween.

Pumpkin plants have large, prickly leaves and produce male and female flowers. Only the male pumpkin blossoms have pollen that is transferred by bees to the female flowers. Pollinated female blossoms develop into pumpkins. But each female flower opens for pollination for only one day. In addition, most pumpkin blossoms are male. As a result, few flowers actually produce pumpkins.

Pumpkins grow on both vines and bushes. Pumpkins that grow on vines are planted in mounds about 12 feet (3.7 meters) apart. Bush varieties are spaced closer together. Pumpkin plants need careful cultivation to produce healthy fruit. The plants thrive in slightly acid soil, and most of them mature about four months after the seeds are planted. Ripe pumpkins that are well developed can be stored at 40 to 50 °F (4 to 10 °C) for several months.

Pumpkins probably originated in North America. Seeds from related plants dating back to 7000 to 5500 B.C. have been found in Mexico. Albert Liptay

Scientific classification. Pumpkin plants belong to the gourd family, Cucurbitaceae. The scientific names of the four pumpkin species are *Cucurbita pepo, C. mixta, C. moschata,* and *C. maxima.*

Pumpkins have a hard outer shell and coarse, stringy pulp. People cook pumpkins in a variety of ways, especially as pumpkin pie. In addition, pumpkin seeds are a popular snack.

Pun is a humorous use of words that sound alike or nearly alike but have different meanings. For example, a rascally character in William Shakespeare's play *Henry V* says, "To England will I steal, and there I'll steal." A pun also may be called a *play on words.* Because a pun condenses more than one meaning into one word, an author can use a pun to present several ideas in a single expression.

Some literary critics, particularly those of England during the 1700's, have called the pun "the lowest form of wit." However, many of the world's greatest writers have frequently used puns. For example, some of the most delightful passages in Shakespeare's early comedies are those in which characters indulge in punning contests. The Irish novelist James Joyce filled his novel *Finnegans Wake* (1939) with clever puns in several languages. Marcus Klein

See also **Humor** (Puns).

Punch and Judy are the main characters in a type of comic puppet show popular in England. Punch is a hook-nosed hunchback who wears a traditional Italian costume. Judy is his wife. A typical Punch-and-Judy show has much rough, violent humor. In the show, Punch usually beats his child, quarrels with his wife, and kills her and sometimes other characters. Punch is brought to trial and sentenced to death, but escapes punishment through trickery.

Robert Harding Picture Library

Punch and Judy are popular puppet characters, especially in England. A typical Punch-and-Judy show is filled with violent comedy involving the quarrelsome Punch, his wife, and baby.

The character of Punch combines English, French, and Italian influences. His name came from Pulcinella, a popular character in Italian theater during the 1600's. Punch-and-Judy puppet shows were introduced into England from continental Europe in 1662. By the 1800's, Punch-and-Judy shows were being presented in portable puppet theaters at fairs or on the streets throughout England. By 1742, Punch-and-Judy shows were brought to America, but they never gained the popularity they enjoyed in Britain. Don B. Wilmeth

See also **Puppet** (Hand puppets).

Punctuation is the use of certain marks in writing and printing to make the writer's meaning clear. The marks are also called *punctuation.*

Early writing and early printing had marks to show punctuation. But the signs were used according to the wish of the writer and to the marks that the printers had

in their typecases. The ancient Greeks, for example, often used a semicolon in place of our modern question mark. Printing and punctuation improved rapidly during the 1400's and 1500's, especially in Italy. During this period, Aldus Manutius, an Italian printer and bookmaker, began to use the various marks more systematically. His work formed the basis of the punctuation used today in many written language systems.

Punctuation marks were used more frequently some years ago. Today, the trend is to use fewer and fewer marks, and in many places to use none at all. Writers today are less bound by the old rules.

The period (.) is used at the end of a statement or command and after most abbreviations. A period follows the sentence you have just read. In American usage, if there are quotation marks at the end of a sentence, the period is placed inside these marks. In British and Australian usage, the period is placed outside the marks. Roman numerals (clxvi, CXXVI) are not followed by periods. Periods are not placed after page numbers in books, but they are placed after numbers in an outline or list. There are no periods after call letters for radio stations, some government bureaus, and some signals sent by code letters, such as *WCFL, FBI,* and *S O S.* Some people, such as printers, call the period the "full stop."

The question mark (?) is used after a question. It is also called the *interrogation mark* or *point.* Every direct question should be followed by a question mark, as *Do you understand this rule?* An indirect question does not end in a question mark. It is followed by a period, as *Inspector Adams wondered who did it.*

The exclamation point (!) is used after a sentence that expresses strong feeling. *How cold it is!* Single words, phrases, or clauses of the same sort are followed by the exclamation point. *Listen! You, over there! Trying to hide!* There are few occasions for using an exclamation point, except in reporting speech.

Quotation marks (" ") enclose the exact words of a speaker. They are sometimes called *double quotation marks,* or *double quotes.* They enclose only the spoken words, as in *"I'm going to telephone Martha," said Bill,* and *"Do you think," Mother asked, "that she has come back from the shore?"*

Quotation marks are used when material is taken word-for-word from another source. For example, an author uses quotation marks to set off text that originated with another author. When several paragraphs are quoted, quotation marks are placed at the beginning of every paragraph and at the end of the last quoted paragraph. Quotations within quotations are enclosed in single quotation marks, as in *"He answered, 'I will not,' when I asked him," she reported.*

Quotation marks may enclose titles of short written works, such as poems, lectures, sermons, and short stories. Quotation marks also call attention to unusual uses of words, such as *a famous "first,"* and to identify nicknames, as in *Eric was called "The Red" because he had red hair.*

The colon (:) has two uses. It is most frequently used after the salutation in a business letter, as *Dear Mrs. Miller:, Gentlemen:, My dear Doctor:, Dear Sir:* . The other use is after such expressions as *to the following:, as follows:* . Often the colon in this use is followed by a list. *The world's three largest countries in area are as follows: Russia, Canada, China.* See **Colon.**

The semicolon (;) is used in a compound sentence between two principal clauses that are not joined by a conjunction. *He struggled to land the bass; it flipped its tail as it vanished.* If principal clauses of a compound sentence contain commas, a semicolon is placed between the clauses even if the conjunction is used. *We rounded the corner yelling, swaying, and grinding; but having used the brakes too late, we skidded against the opposite wall.* The semicolon is also used instead of the comma after items in a series when these items are long or complicated.

The dash (—) is used to mark a sudden break in thought. *I considered her—it was a foolish opinion—too young to take care of herself.* Use dashes to set off emphatically any definition or enumeration in a sentence: *The work of two great English historians—Edward Gibbon and Thomas B. Macaulay—interested Churchill the most.*

Parentheses () enclose parts of the sentence which might easily have been omitted. The material between them is not connected grammatically with the rest of the sentence. *I explained to you (you don't remember when) why I cannot take a long trip.* One mark is called a *parenthesis.* The entire group of words enclosed by the marks is also called a *parenthesis.*

Brackets [ ] in quoted remarks enclose explanations not in the actual speech. *I am a simple man. [Laughter].* Directions in plays may be enclosed in parentheses or in brackets. *But I need money. [He turns away.]*

The comma (,) is the most commonly used mark. It has more uses than any other mark of punctuation. Most of the principal ones are set down here.

It follows the words, phrases, or clauses in a series. *We ate crabs, lobster, shrimp, and fish.*

It follows items in addresses and dates. *He was born at 611 East Minnesota Street, Indianapolis, Indiana, on November 24, 1911.*

It is placed around certain conjunctions, adverbs, and phrases, such as *now, however, for instance,* when it indicates a break in the construction. *Try, for instance, to borrow money without giving security.*

It is used after words, phrases, and clauses at the beginning of sentences unless there is a close connection. *If you perform that experiment again, I shall help you.*

It is used between the principal clauses of a compound sentence unless the sentence is short. *We stood terrified by the swollen stream, but one of us discovered a safe bridge along a huge fallen tree.*

It separates nonrestrictive subordinate clauses from the rest of the sentence. *The listening lad, who had been intently silent, suddenly let out a bloodcurdling yell.*

It sets off a word or phrase which explains some term. The second term is said to be an *appositive* of the first. *Radar, an electronic device, is of value in warfare.*

It sets off words like *well, yes, no,* and all nouns of address. *Yes, we saw the eclipse. Mr. Emerson, may I speak with Jane?*

It sets off quotations, especially in conversation. *"May I," he began shyly, "have the next dance?" "Surely," she answered.*

It is often used to avoid misunderstanding. *Some weeks before she arrived from Canada* is not clear.

Some weeks before, she arrived from Canada is clear.

The hyphen (-) is most commonly used to link compound words, such as *twenty-three, Anglo-American,* and *forget-me-not.* It is also used at the end of a line when a word is broken into syllables and part of the word is put on the next line, as in *atti-tude, di-vision.*

The apostrophe (') is used in the place of omitted letters in contractions, as in *can't, she'll, they're.* It also substitutes for omitted letters in words used in poetry, as in *th', ev'ry,* and *'tis.* The apostrophe is also used to show the possessive case, as in *the student's book, the birds' song, the children's room.* Marianne Cooley

Punic Wars, *PYOO nihk,* were three struggles between ancient Rome and Carthage. Rome won all three wars. The victories made Rome the supreme power of the western Mediterranean and helped Rome gain control of the entire Mediterranean world. *Punic,* the Latin word for *Phoenician,* is used for the wars because Carthage had been founded by the Phoenicians.

The First Punic War (264-241 B.C.) began when Rome intervened to prevent Carthage and Syracuse, a city on the island of Sicily, from controlling the Strait of Messina. The strait lay between Sicily and Italy. Rome became a naval power to meet Carthage on equal terms. Both sides lost several fleets and many men. The war was decided when Rome conquered Sicily and won a final naval battle there.

The Second Punic War (218-201 B.C.) developed from the first war and was caused in part by territorial rivalry in Spain between Rome and Carthage. Hannibal, a great Carthaginian general, crossed the Alps and invaded Italy. The Romans defeated him in the Battle of Zama in 202 B.C. Carthage then paid Rome a large sum and gave up Spain.

The Third Punic War (149-146 B.C.) resulted when Carthage rebelled against the restrictions of the Roman peace treaty of 201 B.C. Carthage was completely destroyed in this war.

Rome won the Punic Wars because it had better resources and more soldiers. Carthage was richer in the beginning, but it had to rely on *mercenaries* (hired troops). Hannibal had proved that mercenaries could fight well, but there were never enough of them.

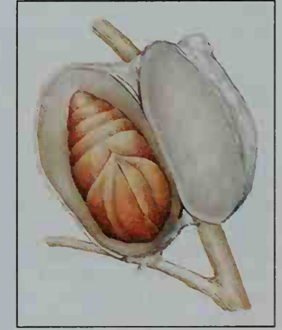
Punishment. See **Capital punishment; Crime; Penal colony; Prison; Reformatory; Sentence** (in law).

Punjab, *PUHN jahb* or *puhn JAHB,* is a region that lies in northwestern India and in Pakistan. The name *Punjab* comes from a Sanskrit word that means *five rivers.* The area is mostly flat, and it is drained by the Indus River and its five tributaries. For location, see **India** (political map); **Pakistan** (political map).

Punjab (Pakistan) (pop. 47,292,441; area 79,284 mi², or 205,345 km²) is a province of Pakistan. Lahore, which is the largest city in the province, has a number of cotton gins and presses. The city also has factories that manufacture textiles, cement, glass, and surgical goods. Islamabad, another city in Punjab, serves as the capital of Pakistan.

The leading economic activity of the province is farming. Punjab province is the leading wheat-producing area of the Indian subcontinent. Millet, maize (corn), sugar cane, oilseeds, rice, citrus fruit, mangoes, pomegranates, dates, and cotton also are grown. Widespread irrigation has made much of the land fertile. From 1950 to 1953, for example, 2 million acres (810,000 hectares) of desert land were reclaimed by irrigation. Minerals, such as coal, gypsum, and limestone, are in the northwestern section of the province.

Punjab (India) (pop. 45,372,285; area 36,515 mi², or 94,574 km²) is a region that consists of two states—Punjab, where Punjabi is spoken, and Haryana, where Hindi is spoken. These states were created from the single state of Punjab in 1966. A portion of the original Punjab state was also included in the territory of Himachal Pradesh.



Indian Punjab is largely a farming region. Timber is found in the northeast part. Cities of Indian Punjab include Amritsar, the holy city of the Sikhs; and Chandigarh, the capital of Punjab and Haryana states. Chandigarh is also a Union Territory of India. Indian Punjab has cotton mills, small engineering plants, metalworks, and glassworks. It also produces cement, sporting goods, and handicrafts, such as carpets and turbans.

Part of the Punjab region was once within the empire of Alexander the Great. Later, Mughal rulers held the area. In the early 1800's, it became a Sikh kingdom under Ranjit Singh. The United Kingdom annexed it in 1849. When India was partitioned in 1947, Punjab also was divided. The eastern section became an Indian state, while the western area, dominated by the Muslims, went to Pakistan. Thousands died as Muslims fled from eastern Punjab, and Hindus and Sikhs moved from Pakistan to India. Sikhs in Punjab have demanded that the Indian government grant them greater control over their own affairs. Violence has occurred from time to time between Sikhs and Indian government forces (see **India** [India under Indira Gandhi]). Robert LaPorte, Jr.

Pupa, *PYOO puh,* is the relatively inactive stage in the *metamorphosis* (development) of most insects. In *complete metamorphosis,* the larva feeds until fully grown (see **Larva**). It then molts into the pupa, a temporary form in which the adult structures develop. The adult insect emerges by splitting open the pupal "skin" and crawling out. The pupal stage may last a day or two, or up to one or more years, depending on the species. This stage enables some adult insects, such as butterflies, to have features that differ greatly from those of the larva. It also allows the developing insect to avoid such conditions as extreme heat and cold, famine, and drought.

The pupa looks different in different species. Butterfly and moth pupae are mummylike with the wings, antennae, and legs encased in the pupal shell.

WORLD BOOK illustration by Shirley Hooper, Oxford Illustrators Limited

Pupa

The pupae of beetles, lacewings, and bees have legs and antennae that hang free. Many insects form a cocoon of silk or other materials and pupate in it. Most moths form cocoons. The butterfly pupa, called a *chrysalis,* hangs from a silklike pad and does not have a cocoon. The housefly and related flies inflate the next-to-last larval skin to form a cocoon called a *puparium.*

Charles V. Covell, Jr.

Pupfish is any of about 30 species of small fish that live mainly in springs and streams in the Southwestern United States and Mexico. Pupfish have inhabited these waters since the last Ice Age, about 50,000 years ago. At that time, rivers and lakes covered the area, much of which is now desert. Isolated groups of pupfish survived after most of the water had dried up. One species, the *Devils Hole pupfish,* has lived over 20,000 years in a deep spring in Nye County, Nevada. This area is now in Death Valley National Park.

Several species of pupfish have become extinct, and other species are endangered. In the 1970's, scientists and conservationists began working to protect the surviving species. The Devils Hole pupfish has been legally protected since 1976. The population of this species has been reduced to only about 200 individuals at times.

Pupfish can live in water where few plants and animals can survive. Some pupfish normally withstand water temperatures up to 108 °F (42 °C). Pupfish have an average length of about 1 $\frac{1}{2}$ inches (3.8 centimeters). The females and young are olive brown and white, with black bars on their sides. The males are blue and purple, with black bars and dark-edged fins.

Scientific classification. Pupfish belong to the killifish family, Cyprinodontidae. They are genus *Cyprinodon.* The scientific name for the Devils Hole pupfish is *C. diabolis.* The Salt Creek pupfish is *C. salinus.* Tomio Iwamoto

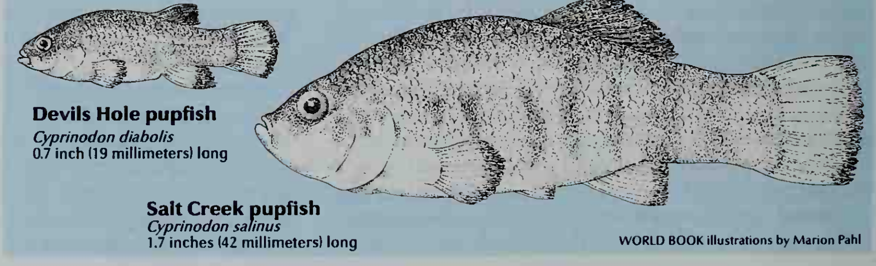
Pupil. See **Eye** (The uveal tract; picture: The iris).

Pupin, *pyoo PEEN,* **Michael Idvorsky,** *ihd VAWR skee* (1858-1935), was a Serbian-American electrical engineer, educator, and inventor. In 1900, he patented the *loading coil,* a device that improved telephone sound quality and enabled people to talk on the telephone over much greater distances than before. Pupin came to the United States in 1874 and taught at Columbia University from 1889 to 1931. In 1924, he received a Pulitzer Prize for his autobiography, *From Immigrant to Inventor* (1923). He was born in Idvor, north of Belgrade in what became Yugoslavia. James E. Brittain

Puppet is an artificial figure whose movements are controlled by a person. Puppets can be moved by hand or by strings, wires, or rods. A figure may represent a person, an animal, a plant, or an object. Puppets usually appear as characters in plays called *puppet shows.* A person who operates a puppet is called a *puppeteer.*

Many children make puppets from such cheap materials as paper, cloth, and wood, or from such items as milk cartons and rags. They write puppet shows and operate the puppets, varying their voice for each character. A table or bookcase can serve as a stage. A puppeteer can also work behind a blanket or sheet tacked across the lower part of a doorway. The puppeteer is concealed, and so the audience sees only the puppets performing in the upper part of the doorway.

Some teachers use puppets to make schoolwork more interesting. For example, a history class may use puppets to act out a famous historic event. Students can improve their knowledge of a foreign language by writing and performing puppet shows in that language. Creating a voice for a puppet has helped some students overcome a speech problem. In underdeveloped countries, puppet shows have been used to teach health care, modern farming methods, and other subjects.



People have enjoyed puppets for thousands of years. Puppetlike figures have been found in tombs and ruins in ancient Egypt, Greece, and Rome. The first puppets were probably used in religious ceremonies. Priests secretly moved the eyes or arms of an idol or religious carving to impress the people watching.

There are three main kinds of puppets: (1) hand puppets, (2) marionettes, and (3) rod puppets. Many puppets have features of more than one type.

Hand puppets are the most common puppets. One variety, the *glove* or *fist* puppet, consists of a hollow head attached to a glove or a piece of cloth that serves as the puppet's body. The body fits over the hand of the puppeteer, who puts a thumb into one of the puppet's arms. One or two fingers go into the other arm, and the remaining fingers are placed in the head. These puppets can pick up things and can gesture with their head and arms. Most glove puppets have no legs or feet.

Perhaps the most famous glove puppet character is Punch, the star of English puppet shows called *Punch and Judy shows.* Punch was introduced into England in 1662 (see **Punch and Judy**). Puppet characters that resemble Punch are popular in several countries, including France, Germany, Italy, the Netherlands, and Switzerland. Glove puppets have become a popular feature of several children's television programs, such as "Sesame Street" and "Captain Kangaroo."

The simplest kind of hand puppet is probably the *finger puppet.* Some finger puppets fit over the upraised finger with the face over the fingernail. In others, two

Pupfish have lived in the waters of southwestern North America for thousands of years. The *Devils Hole pupfish* is found only in a small spring in Nevada. The *Salt Creek pupfish* lives in a California stream where temperatures reach over 100 °F (38 °C).

Salzburg Marionette Theater, Austria

Marionettes are moved by strings or wires attached to their body and controlled by puppeteers who are hidden above the stage. The scene at the left shows three women battling a serpent in a marionette version of the opera *The Magic Flute.*

fingers serve as the puppet's legs. The face may be painted on the back of the hand, or a paper head can be fastened with a rubber band.

Another type of hand puppet, the *muppet,* was developed for television by the American puppeteer Jim Henson. This small puppet, usually made of foam rubber or other soft material, has a wide mouth, with the puppeteer's thumb inside the lower jaw. The fingers form the upper part of the muppet's face. The puppeteer moves various fingers to change the muppet's expression and the shape of its head. The puppeteer's other hand, which is concealed in a glove, forms the muppet's body or hand. See **Henson, Jim.**

Marionettes are puppets controlled by strings or, in some cases, by wires. A marionette has a complete body, with head, trunk, arms, hands, legs, and feet. Strips of cloth, leather, or other flexible material connect the various parts of the marionette's body. Most marionettes have strings that run from the head, shoulders, hands, and knees to *the control,* a small wooden frame. One or more puppeteers, who are hidden above the stage, operate the marionettes by moving the strings where they are fastened to the control.

The word *marionette* comes from *Little Mary,* a type of puppet of the Middle Ages. During this period, many people could not read or write. Priests used Little Marys to teach stories from the Bible. Marionette shows gradually became comic plays that were intended to entertain rather than teach religious lessons. But the plays grew so coarse and worldly that religious authorities refused to let them be performed in churches. Marionette shows then became *street entertainments* that were performed in parks and at fairs.

Rod puppets are operated by rods or sticks, usually from below the stage. One kind of rod puppet, the *marotte,* consists only of a head mounted on a stick. Some rod puppets have rods attached to movable arms and hands. Rod puppets are often used to represent figures other than people and animals. For example, they may portray clouds, flowers, hats, trees, or just simple shapes.

Japan has a well-known form of puppet show called *bunraku* (doll theater). The puppets stand about 4 feet (120 centimeters) tall. They look realistic, with flexible joints and movable eyes, mouth, and eyebrows. As many as three puppeteers operate them with rods from behind, in full view of the audience. Many important Japanese dramatists of the late 1600's and 1700's wrote plays especially for the doll theater. See **Drama** (Asian drama [Japan]).

Shadow plays are a type of puppet show in which all types of puppets can be used. The puppeteer operates the puppet against a thin screen made of silk or cotton. A strong light shines on the screen from behind and above. The audience, which sits on the other side of the screen, sees only the moving shadows of the puppets.

One kind of puppet, a flat figure made of leather, is made especially for shadow plays. Such puppets, which are popular in Asia, may have movable parts operated by rods made of bamboo or animal horn. The Chinese

Martine Franck, Woodfin Camp, Inc.

Rod puppets are featured in a traditional form of Japanese theater called *bunraku, above.* Puppeteers use rods to operate the figures, which stand about 4 feet (120 centimeters) tall. The puppeteers, dressed in black, work in full view of the audience.

Victor Englebert, De Wys, Inc.

Shadow puppets perform behind a screen. A light from above and behind the puppets creates shadows on the screen. The audience sees only the shadows. Shadow plays based on Hindu myths, *shown here,* are the most popular form of theater in Indonesia.

and Turks create colored shadows on the screen by dyeing the leather figures. In Indonesia, a popular form of puppet theater called *wayang kulit* (leather shadow puppets) presents plays based on Hindu myths. The performances begin in the early evening and last until dawn. See **Indonesia** (The arts).

Dummies are puppets that play an important part in ventriloquism. The ventriloquist pretends to talk to the dummy, which is held on the knee or on a chair. The ventriloquist "throws" his or her voice so that the dummy seems to be speaking. Rods and strings inside the puppet enable the ventriloquist to move the puppet's head and parts of its face from the back. See **Ventriloquism** (picture).

Organizations for puppeteers help people improve their technique with puppets. The Puppeteers of America has members in the United States, Canada, and about 20 other countries. The Union Internationale des Marionettes (UNIMA) is another international organization of puppeteers. The headquarters of UNIMA are in Warsaw, Poland, and the organization has national chapters in the United States, Canada, and about 15 other countries. Puppet centers have been established in Atlanta, Georgia; Boston; Toronto, Canada; and London. Their puppet exhibitions and performances by leading puppeteers provide exposure to the art of puppetry.

How to make a hand puppet

To make the face, the girl uses common materials found in the home. She first glues on an eye made of felt to the end of a white sock, *left.* The sock serves as the puppet's head and body. She then sews on eyelashes made of yarn, *right.*

To complete the head, the girl adds hair by sewing long strands of yarn onto the sock, *left.* She draws the puppet's mouth with ink, *right.* She also used ink to draw the eyebrows. She can add other decorations to the head and body.

WORLD BOOK photos

Two hand puppets perform on a box that serves as a stage. The puppet on the left consists of a head and body made from paper bags and decorated with colored paper, straws, and yarn.

Purcell, *pur SEHL,* **Edward Mills** (1912-1997), an American physicist, shared the 1952 Nobel Prize for physics. He received the award for developing and applying a simple but precise method for determining the magnetic properties of nuclei. Purcell also made important contributions to radio astronomy. In addition, Purcell served as an adviser to the United States government on science policy. He was born in Taylorville, Illinois. In 1949, he became a professor of physics at Harvard University. Robert H. March

Purcell, *PUR suhl,* **Henry** (1659?-1695), was an English composer during the baroque period. He wrote religious music, as well as music for the theater and ceremonial music for the English court. Purcell is admired for his original harmonies and for his skillful setting of the English language in his choral music. Purcell was aware of musical developments in other countries. His trio sonatas and many of his songs for the theater are modeled on the Italian style. Some of his religious anthems imitate French fashions.

Purcell wrote one of the earliest English operas, *Dido and Aeneas* (1689). It contains a famous song, "When I am laid in earth" ("Dido's Lament"), composed in one of Purcell's favorite forms, called *ground bass.* This form uses a short melodic theme in the bass part repeated over and over with changing harmonies.

Purcell was born in London. As a boy, he sang in the choir of the Chapel Royal, the king's private chapel. In 1679, Purcell was organist of Westminster Abbey, and in 1682 he became an organist of the Chapel Royal.

Joscelyn Godwin

Purdue University is a publicly controlled coeducational land-grant school. Its main campus is in West Lafayette, Indiana. The university also has regional campuses in Fort Wayne, Hammond, and Westville. Purdue operates the Fort Wayne campus jointly with Indiana University. Both universities also offer courses at Indiana University-Purdue University at Indianapolis (see **Indiana University**). Purdue is supported by the state of Indiana, but it also receives aid from the federal government and various private sources.

Purdue is well known for its engineering programs, having schools of chemical, civil, electrical, industrial, materials, and mechanical engineering. Purdue also has a school of aeronautics and astronautics, and departments of agricultural and nuclear engineering. In addition, there are schools of agriculture; consumer and family sciences; education; liberal arts; management; pharmacy and pharmacal sciences; science; technology; and veterinary medicine. Purdue also has a graduate school and a research foundation. Courses at the university lead to associate, bachelor's, master's, and doctor's degrees.

Purdue's Hall of Music is the largest college auditorium in the United States, seating over 6,000 people. The Ross-Ade stadium is named in honor of two Purdue graduates—David Ross, an inventor and manufacturer, and George Ade, an author and humorist. Purdue was founded in 1869 and is named for John Purdue, one of the university's earliest benefactors.

Critically reviewed by Purdue University

Purdue University

Purdue's main campus is located in West Lafayette, Indiana. The university is noted for its engineering programs. Purdue's enrollment is one of the largest in the United States.

Pure food and drug laws establish health and safety standards for foods, drugs, medical devices, and cosmetics. The basic food and drug law of the United States is the Federal Food, Drug, and Cosmetic Act. This act, which was passed in 1938, prohibits the distribution of impure foods, drugs, or cosmetics in the United States. It also forbids false or misleading labeling on such products.

The Food and Drug Administration (FDA)—an agency in the Department of Health and Human Services—enforces the Federal Food, Drug, and Cosmetic Act. The FDA checks food and drug products to make certain they meet federal standards. If the FDA finds evidence of violations, it gives the evidence to a federal court. Federal courts receive several hundred new cases annually that deal with such violations.

Foods

A major section of the Federal Food, Drug, and Cosmetic Act gives the FDA power to set standards for both human and animal foods. Food standards define what ingredients a food must contain and how the food should be labeled. The FDA sets standards for only the most common food products. The food section of the federal act contains provisions that cover (1) impurities in foods, (2) food additives, and (3) labeling of foods.

Impure foods are foods that do not meet the safety, purity, or cleanliness standards of the Federal Food, Drug, and Cosmetic Act. They include foods that have dirty or rotten contents or have been prepared or packaged under unsanitary conditions. The most frequent sources of impurities found in food are insects, mice, and rats.

In addition, harmful chemicals may be the cause of impurities. Such chemicals may be present in food on which producers have used a poisonous spray. Harmful chemicals also may be found in fish that have lived in polluted water.

Food additives are substances that food producers can legally add to their products. They include spices and many other substances used to flavor or preserve food. The Federal Food, Drug, and Cosmetic Act requires that these substances be proved safe by scientific tests before they are put on the market. About 2,800 food additives have been approved. Permitted additions to foods also include color additives. The FDA must ap-

Centers for Disease Control and Prevention

Pure food and drug laws protect consumers from impure and unsafe food and drugs. In the United States, the Food and Drug Administration (FDA) enforces such laws. This FDA technician is testing for a disease spread by contaminated food and water.

prove every batch of color that is used in the preparation of foods, drugs, and cosmetics.

The safe use of pesticides is also permitted. Food growers often use pesticides on or around food. The Environmental Protection Agency determines how much pesticide may remain on a food crop. It sets these levels far below those that would make the food dangerous to eat. The FDA tests food products for pesticide and takes them off the market if too much remains on them.

Labeling of foods. The Federal Food, Drug, and Cosmetic Act requires food producers to provide certain information on the labels of their products. This information includes the name of the product and of its manufacturer, packer, or distributor; the amount of food in the package or container; a complete list of ingredients, except for some standardized foods; and the name of any chemical substance added. In addition, a food label must tell if artificial color or flavor has been used, except for some colors that are added to butter, cheese, and ice cream. The Nutrition Labeling and Education Act of 1990 requires that all packaged and processed foods sold in the United States also carry labels with nutritional information (see Nutrition [Nutrition guidelines]).

Drugs and devices

The Federal Food, Drug, and Cosmetic Act defines drugs as products intended for use in the medical care of people or animals. The act covers several kinds of drugs, including (1) prescription drugs, (2) over-the-counter drugs, (3) biological drugs. It also covers medical and other devices.

Before a producer can sell a new drug, the drug must be tested thoroughly to find out if it is safe and effective when used as directed. The producer must give the FDA a report on all tests and on all the ingredients of the drug and the methods for testing their strength and purity. The producer must submit the proposed label directions and any needed warnings. The FDA, after approving a new drug, keeps watch on its use and effects.

Prescription drugs are dangerous to use except under medical supervision. The Federal Food, Drug, and Cosmetic Act defines the kinds of drugs that should be in this group. The act forbids the sale of such drugs unless a physician or a dentist has prescribed them. The act also prohibits the sale of a prescription drug for an animal unless a veterinarian has prescribed it.

Over-the-counter drugs may be sold without a prescription. Such drugs must be safe for use without medical supervision. Label directions and warnings on over-the-counter drugs must be clear and easily seen, so that consumers can use the drugs safely and effectively.

Biological drugs are made from animal or human substances. These drugs include serums and vaccines, and drug products made from human blood. A manufacturer may not sell such a drug unless the FDA has licensed it. An FDA license assures the purity, safety, and strength of the drug.

Devices. Medical devices are products used in the control or treatment of disease. The Federal Food, Drug, and Cosmetic Act requires them to be safe and effective. Such devices include artificial parts for the human body, fever thermometers, and sun lamps. Many medical devices need FDA approval before they go on the market. The FDA also tests radiation-emitting devices such as X-ray machines, televisions, and microwave ovens to ensure that they do not endanger health.

Cosmetics

Cosmetics include such products as deodorants, lipsticks, perfumes, shampoos, and toothpaste. The Federal Food, Drug, and Cosmetic Act requires cosmetics to be safe and properly labeled. It also requires cosmetic producers to make and package their products under sanitary conditions. The ingredients used in a cosmetic must be listed on the label. The labels must include the manufacturer's name and address. Labels of coal tar hair dyes must warn that the product should be tested for possible skin irritation before being used.

Enforcement

The Food and Drug Administration publishes regulations that explain the Federal Food, Drug, and Cosmetic Act. However, manufacturers sometimes violate the act, accidentally or intentionally. In most cases, the FDA does not prosecute if the manufacturer voluntarily stops

shipping an illegal product. If an illegal product has already been sold, the manufacturer may be required to notify the people who bought it and arrange to take the unsold stocks of the product off the market. This procedure is called a *recall.*

Evidence of violations of the act is gathered by about 1,100 field investigators and inspectors. These FDA employees inspect factories and warehouses and investigate complaints of illness or injury caused by impure or mislabeled foods, drugs, or cosmetics. In addition, FDA inspectors supervise the enforcement of court rulings on violations.

The FDA also employs about 925 scientists in field jobs, including microbiologists, chemists, and veterinarians. These experts use laboratory tests to check the purity, safety, and effectiveness of foods, drugs, cosmetics, and devices. The FDA employs hundreds of other scientists and physicians who review and approve new drugs and serve as experts in other scientific areas.

Three kinds of legal action can be taken if the FDA finds that a producer has violated the federal food and drug laws: (1) A federal court may issue an *injunction* (court order) directing the manufacturer to stop. (2) The court, acting on evidence from the FDA, may seize a product that violates the law. (3) Prosecution for such violations can result in a fine or imprisonment or both.

History

Since ancient times, there have been food and drug laws regulating the quality of meat, milk, and flour products. By about A.D. 1300, European merchants had set up powerful trade organizations to inspect food and drugs. During the Industrial Revolution, which occurred in the 1700's and early 1800's, food producers began using chemicals to preserve and color food.

In 1784, Massachusetts passed the first general pure food and drug law in the United States. Early state laws were difficult to enforce, however, because they often did not define *pure,* and what was considered pure in one state could be ruled impure in another. Also, some people felt it was unfair to punish a merchant for selling foods or drugs that the merchant did not know were considered impure in a particular state.

In 1848, Congress passed the first federal drug law, the Import Drug Act, to stop drugs of poor quality from coming into the country. Beginning in 1883, Harvey W. Wiley, chief of the Bureau of Chemistry in the U.S. Department of Agriculture, began studies of food purity. He favored passage of a federal law that would define impure and misnamed foods and drugs for all states. Public support for passage of such a law grew as journalists wrote about certain chemical preservatives and other harmful substances in foods and about dangerous ingredients, such as alcohol and opium, in drugs. As a result, Congress passed two food and drug acts in 1906—the Meat Inspection Act and the federal Food and Drugs Act. Stronger legislation—the Federal Food, Drug, and Cosmetic Act—was passed in 1938. The act has been revised many times since then.

Food and drug laws in Canada

Parliament passed Canada's first food and drug law in 1875. Today, the nation's main food and drug law is based on the Canadian Food and Drugs Act of 1920. Other important Canadian food and drug acts include the Narcotic Control Act and the Proprietary or Patent Medicine Act.

The Canadian food and drug acts prohibit the production or sale of impure food and drug products. Like the United States laws, these acts set standards of purity and safety for foods, drugs, cosmetics, and medical devices. The acts are enforced by the Health Protection Branch of the Department of National Health and Welfare.

In 1995, the FDA declared that nicotine was a drug and that cigarettes and other tobacco products were nicotine "delivery devices." As a result, the FDA introduced restrictions on the marketing and sale of tobacco products to young people. In 2000, however, the Supreme Court of the United States ruled that the FDA does not have the authority to regulate tobacco products. Critically reviewed by the Food and Drug Administration

Purgatory, *PUR guh TAWR ee,* is a state, according to Roman Catholic tradition, in which people who have died atone for their sins before being admitted to the vision of God in heaven. In purgatory, those who have been in the friendship of God make full amends for their failings by suffering. People can reduce their future suffering by engaging in various religious or pious acts before death. Those who are already in purgatory can be helped by the prayers of the living. Joseph M. Hallman

Purim, *PU rihm* or *poo REEM,* is a joyous Jewish festival celebrated in February or March, on the 14th day of the Hebrew month of Adar. It commemorates the rescue of the Jews of Persia from a plot to kill them.

The story of Purim is told in the Book of Esther in the Bible. Esther was the beautiful Jewish queen of King Ahasuerus of Persia. Her uncle Mordecai advised her, however, not to reveal that she was Jewish. The king's wicked minister, Haman, persuaded Ahasuerus to have all the Jews in the empire killed. Haman drew lots to determine the day of their execution. The word *Purim* comes from the Hebrew word *pur,* which means *lot.* Mordecai and Esther decided to tell the king that Esther was Jewish and to plead with him to spare her people from destruction. First Esther fasted in preparation for her visit to the king, and then she revealed her Jewish origins. Ahasuerus was angry with Haman and had him killed for his plot. He then appointed Mordecai as minister.

Jews celebrate the survival of their people with great merriment. The Book of Esther, called the Megillah, is read in the synagogue. People send gifts of food to their neighbors and give charity to the poor. People dress in costumes representing Esther, Mordecai, Haman, and Ahasuerus, and hold carnivals. Jewish tradition established the Fast of Esther on the day before Purim to commemorate Esther's fast and her courageous deeds (see **Esther, Book of**). Lawrence H. Schiffman

Puritans, *PYUR uh tuhnz,* were members of a religious and social movement of the 1500's and the 1600's. The

movement began in England and spread to America where it greatly influenced social, political, and religious institutions. Such religious denominations as Congregationalism and Unitarianism developed from Puritan beliefs.

Puritan beliefs developed from the teachings of religious reformers, such as John Wycliffe and John Calvin. Wycliffe was a famous professor of philosophy at Oxford University during the 1300's. Calvin was a leader of the *Reformation,* the religious movement of the 1500's that gave rise to Protestantism.

The Puritans considered the Bible as the true law of God that provided guidelines for church government. They wished to shape the Church of England to meet their ideals. They called for a less priestly church that emphasized preaching. Puritans believed that all Christian churches should be organized through councils called *presbyteries* or *church courts* rather than under bishops, as in the Church of England. Some Puritans believed that each congregation was a complete church in itself and should have total control of its own affairs.

The Puritans emphasized Bible reading, prayer, and preaching in worship services. They simplified the ritual of the sacraments. They also wanted more personal and fewer prescribed prayers. The Puritans stressed grace, devotion, prayer, and self-examination to achieve religious virtue.

History. The term Puritan was first used in the late 1500's to identify a party within the Church of England, the national church. The party sought to make further changes in the church than had been brought about by Protestant reforms during the reigns of King Henry VIII, King Edward VI, and Queen Elizabeth I. Defenders of these reforms called the party members Puritans because of their proposals to "purify" the church.

As early as the 1520's, English Protestant leaders had demanded reforms along the lines that were later called Puritan. In the 1520's and 1530's, William Tyndale published pamphlets and English translations of the Old Testament and New Testament designed to encourage such reforms. Hugh Latimer, who became an important Protestant bishop, also had raised such protests to purify the church.

Many English Christians agreed with the demands of Tyndale and Latimer that the church and the government be operated according to the Bible. These Christians believed that the Bible governed all human affairs. John Wycliffe had taught this doctrine at Oxford in the 1300's. Under King Edward VI and Queen Elizabeth I, these teachings received support from English clergymen who followed Calvin's doctrine that the New Testament described how the church should be run.

During the 1600's, the Puritans increasingly opposed the political and religious policies of the Stuart rulers, King James I and his son, King Charles I. In 1604, James I called the Hampton Court Conference to settle disagreements within the Church of England. However, James refused to bring about the reforms the Puritans sought, except for a new translation of the Bible, now called the King James Version.

The Puritans gained in strength in Parliament, and repeatedly introduced legislation against the Crown's policies. In 1642, civil war broke out between the Crown forces, called *Royalists* or *Cavaliers,* and the Puritans, called *Roundheads.* They received this name because they cut their hair short. This English Civil War is also called the *Puritan Revolution.*

The Puritans, led by Oliver Cromwell, won a series of victories and took control of the government in 1649. The Puritans closed theaters and passed other unpopular measures. Their political power ended after Cromwell died in 1658. In 1660, the Stuart dynasty returned to the throne.

Political aspects of the Puritan movement lived on in the policies of the Whig Party in England. Puritan religious ideals were revived in the rise of the Methodist Church in the 1700's.

During the 1600's, some Puritan groups believed that

reform of the Church of England was impossible and departed to settle in North America. They founded settlements in Virginia and along New England's coast, especially in Massachusetts Bay Colony and Connecticut.

The Puritans shaped religion, social life, and government in North America to their ideals. Their strong belief in education led them to establish Harvard and Yale as colleges and to require a system of grammar schools in the colonies. The Puritans organized their government according to the teachings that they found in the Bible and on the basis of their English experience.

Late in the 1500's, some Puritans separated from the Church of England and set up their own congregations. Such groups were called *Separatists.* A group of English Separatists first went to Holland and then founded Plymouth Colony in what is now Massachusetts in 1620. This group of Puritans is better known as *Pilgrims.* Some Separatists moved to Rhode Island and became Baptists. Others joined the Massachusetts Bay Puritans and became Congregationalists. Thus, while the Puritan movement in England died down, it influenced Protestant denominations in England and America.

Puritan influence also shaped political and social institutions in England and the American Colonies. In England, the Puritan Revolution led to a greater emphasis on *limited* or *constitutional monarchy,* in which a constitution, legislature, or both limit the power of a ruler. The Puritans' belief in government by contract from the governed influenced the development of American democratic principles.

Over time, the term *puritan* has broadened to mean a strictness in morals or religious matters. The term is commonly applied to cultural traits found in the literature of, and social attitudes shared by, the New England Colonies. Such traits include an emphasis on education and the glorification of hard work.

The word puritan has also been used to describe reforming attitudes and activities that were not part of the culture of the Puritans. For example, *prohibition,* the forbidding of the sale or manufacture of alcoholic beverages, and *temperance,* the avoidance of alcohol, are often called puritan movements. But the Puritans did not disapprove of the use of alcohol. In addition, the term puritan has come to describe the moral attitudes and values that characterize modern movements for rapid social change that require discipline and hard work.

Many social scientists have studied the role of the Puritans in the development of modern social patterns. The German sociologist Max Weber associated the Puritan belief in hard work with the rise of the free enterprise system. Others emphasize the connection between the behaviors and beliefs of the Puritans and those of modern revolutionaries. John F. Wilson

Purslane, *PURS layn,* is a matting annual weed. It is one of the worst pests in American gardens and cultivated fields. The plant covers a sizable area and is also a home for insects that feed on corn and melons. It has thick, fleshy leaves and stems, and yellow flowers. The purslane bears many seeds, and it is important to destroy the plant before the seeds ripen. Young shoots are sometimes eaten in salads.

Grant Heilman

Purslane

Harold D. Coble

Scientific classification. Purslanes belong to the purslane family, Portulacaceae. Purslane is *Portulaca oleracea.*

Pus. See Abscess.

Pusan, *poo sahn* (pop. 3,798,113), is the second largest city and the major port in South Korea. Only Seoul has more people. Pusan lies on the southeast coast of the Korean Peninsula. For location, see **Korea** (political map).

Pusan's harbor can accommodate about 80 large ships at a time, and the city's port handles millions of tons of cargo yearly. The city is an important center of South Korea's fishing industry. Pusan is also an administrative, commercial, and industrial center. The large number of industries located in and near the city produce chemicals, electric and electronic equipment, machinery, plywood, rubber goods, ships, and textiles. Pusan has an underground rapid-transit system and an international airport.

Pusan is also a tourist center. The region's beaches and hot springs attract many visitors. Two religious landmarks in the Pusan area also attract visitors. Tongdosa and Pomosa are both large, beautiful Buddhist temple-monastery complexes of buildings that lie on the slopes of wooded hills. The United Nations Cemetery is near Pusan. It contains the graves of armed forces personnel from nations that fought as allies in the Korean War (1950-1953).

Pusan dates from ancient times. During the Korean War, it served as the temporary capital of South Korea and was the chief landing and supply port of the United Nations forces. Pusan's population has increased sharply since the war. Today, the city suffers from a shortage of housing. Chong-Sik Lee

Pushkin, Alexander (1799-1837), is considered Russia's greatest poet and, by many, the greatest Russian writer of any kind. He is known as the father of Russian literature and modern Russian literary language.

His works. Pushkin wrote in a wide variety of poetic and prose styles. He first achieved fame for long, narra-

tive poems similar to those of the English poet Lord Byron, but he was also a master of lyric poetry and wrote plays in verse. In the late 1820's, he turned to prose and produced a series of outstanding short stories, novellas, and novels. He was also a brilliant literary critic, letter writer, and historian. In addition to his unparalleled influence on Russian literature, Pushkin's works provided subjects and inspiration for Russia's leading artists, composers, and *choreographers* (dance composers).

Pushkin's most famous work is *Eugene Onegin* (1825-1832), a novel in verse. The title character is intelligent, good-hearted, and liberal but lacks moral discipline and a serious occupation or purpose in life. As a result, he destroys himself and those around him. Much of the story deals with Onegin's relationship with a beautiful country girl named Tatyana. These figures, the weak Eugene and the sincere Tatyana, became models for characters in later Russian literature.

Pushkin's drama *Boris Godunov* (written in 1825, published in 1831), written in blank verse, introduced Shakespearean historical tragedy to the Russian stage. The play tells the story of the guilt of Czar Boris, who, Pushkin believed, had ascended to the throne by murdering the rightful heir, the infant Dmitriy. In 1830, Pushkin also wrote four "little tragedies" in verse, which were not intended for staging. The most famous are "The Stone Guest" and "Mozart and Salieri."

Pushkin wrote lyric poems about love, nature, and the obligations of poetry and the poet in Russia. His five prose stories, the *Tales of Belkin* (written in 1830), differ from the conventional romantic prose of his time in their realism. "The Queen of Spades" (1834) is perhaps his most popular short story.

His life. Alexander Sergeyevich Pushkin was born in Moscow. One of his great-grandfathers was a black Ethiopian courtier to the Russian ruler Peter the Great. Pushkin took great pride in his black ancestry and noble heritage. Even as a student, Pushkin was viewed as the great poetic genius of the nation.

The czar's secret police began to watch Pushkin after he wrote the ode "Liberty" and several poems that criticized important government officials. In 1820, he was exiled first to southern Russia and later to his family estate, called Mikhailovskoye near Pskov. In 1826, a new czar, Nicholas I, called Pushkin to St. Petersburg and gave him a pardon. For the rest of his life, Pushkin combined writing with historical research, particularly on the reign of Czar Peter I. His greatest narrative poem, *The Bronze Horseman* (1833), deals with that period.

In 1831, Pushkin married Natalya Goncharova, a beautiful woman in St. Petersburg society. She acquired numerous male admirers at court. Easily made jealous, Pushkin challenged one of the admirers to a duel in January 1837 and was mortally wounded. The entire Russian intellectual community perceived his early death as a national tragedy. Pushkin's death is the subject of great poems by several Russian writers. Anna Lisa Crone

Pushtuns. See Pashtuns.

Pussy willow is a shrub or small tree of the willow family. It grows wild in eastern North America from Nova Scotia south to Virginia and west to Missouri. Pussy willows grow best in moist places, but they also can be found on dry soils. They seldom grow taller than 20 feet (6 meters). They have several long, straight twigs without side branches. The twigs have many flower buds.

In early spring, before the leaves unfold, the flower clusters break out of the hard buds. These clusters are called *catkins*. Male and female catkins grow on sepa-

Grant Heilman

Pussy willow flowers appear in spring. At first, the flower clusters have a coat of silky, grayish-white hair. The male clusters later develop into loose masses covered with yellow pollen.

rate trees. The catkins are long, round, and covered with a dense coat of silky, grayish-white hair. They have been said to resemble tiny kittens climbing up the twig. Later the male catkins develop into larger, loose masses covered with yellow pollen. Richard C. Schlesinger

Scientific classification. The pussy willow belongs to the willow family, Salicaceae. Its scientific name is *Salix discolor*. Several other species of willow with silky catkins are also known as pussy willows.

Putin, *POO tihn,* **Vladimir Vladimirovich,** *VLAH duh meer VLAH duh MEER uh vihch* (1952-), is the president of Russia. He worked to strengthen the federal government and to reign in local government officials and powerful business interests. Under Putin's leadership, Russia developed friendlier relations with Europe and the United States.

In 2002, Russia entered into a special partnership with the North Atlantic Treaty Organization (NATO), a military alliance originally formed to oppose the Soviet Union. A new NATO-Russia Council allows Russia to work more closely with NATO members on various security issues. That same year, Putin and United States President George W. Bush signed a treaty to reduce the number of nuclear weapons in both countries.

Putin was born in Leningrad (now St. Petersburg). He earned a law degree from Leningrad State University in 1975. Putin served in the KGB, the intelligence-gathering and security force of the Soviet Union, from 1975 to 1990.

AP/Wide World

Vladimir Putin

In 1990, Putin returned to Leningrad and worked in the city's government. In 1996, he was invited to Moscow to serve in Russia's federal government. In 1997, Putin earned an advanced degree in economics from St. Petersburg State Mining Institute.

Putin advanced within President Boris N. Yeltsin's administration, holding a variety of positions. In 1998, he was named head of the Federal Security Service, a successor to the KGB. In August 1999, Yeltsin chose Putin as prime minister. Putin became acting president of Russia on Dec. 31, 1999, after Yeltsin resigned. Putin was elected president by the people of Russia in March 2000.

Stuart D. Goldman

Putnam, Herbert (1861-1955), an American librarian, was librarian of Congress longer than any other person who ever held the position. Appointed by President William McKinley in 1899, he served until he retired in 1939. He was the first experienced professional librarian to become librarian of Congress. Before his appointment, he held posts as librarian of the Boston Public Library and president of the American Library Association.

During the late 1800's, the Library of Congress began to develop beyond its original purpose as a legislative reference library and become a national institution. Putnam oversaw several important milestones in this development. He felt strongly that the library should serve the American people and focused many of his efforts on creating programs to encourage widespread public use. For example, under Putnam's leadership, scientific investigators and other qualified individuals gained access to the library's vast collections. He also began an extensive interlibrary loan service that made materials in the collections available to local institutions. Putnam was born in New York City. Gregory Allan Finnegan

See also **Library of Congress**.

Putnam, Israel (1718-1790), an American patriot, was a general in the Revolutionary War in America (1775-1783). One of the few experienced soldiers at the war's start, he rose from the rank of second lieutenant to lieutenant colonel in the French and Indian War (1754-1763). He became a major general in the Continental Army.

During the difficult years before the war, Putnam was a stout opponent of the British government. He became a leader in the Sons of Liberty and served as chairman of the Brooklyn (Connecticut) Committee of Correspondence. When Putnam heard about the Battle of Lexington, he hurried to Cambridge and joined the colonial soldiers. Later, he fought in the Battle of Bunker Hill.

Putnam was born in Salem Village (now Danvers), Massachusetts. During the French and Indian War, the Indians captured him, but he escaped from death through a dramatic rescue. In 1762, Putnam led a Connecticut regiment in an unsuccessful expedition against the French in the West Indies. James H. Hutson

Putnam, Rufus (1738-1824), an American general in the Revolutionary War in America (1775-1783), became known as the founder and father of Ohio. Putnam and others organized the Ohio Company in 1786 to colonize the territory located northwest of the Ohio River. Putnam was in charge of the first colony of settlers, and, in 1788, he established the first permanent white settlement at Marietta, Ohio.

Putnam was born in Sutton, Massachusetts. He served three years as a soldier in the French and Indian War (1754-1763). In 1761, he settled in North Brookfield, Massachusetts, and worked as a millwright and surveyor. Putnam became a lieutenant colonel in the Continental Army when the Revolutionary War began. He planned and built the fortifications around Boston so well that, in 1776, he was appointed chief engineer of the army, with the rank of colonel. Putnam served in many engagements, and he became a brigadier general in 1783. In March 1790, Putnam was appointed a judge of the Northwest Territory. In 1796, he became surveyor general of the United States. Richard J. Hopkins

Putrajaya, *poo trah JAH yah* (pop. 7,000), is a new city being built to serve as Malaysia's administrative capital. The city did not exist before the government planned and built it. Construction began in 1995. Besides government offices, Putrajaya features residential areas, botanical gardens, parks, and wetlands. It lies about 20 miles (32 kilometers) south of Malaysia's capital, Kuala Lumpur.

Putrajaya is part of a plan by Prime Minister Mahathir bin Mohamad to develop the high-technology sector of Malaysia's economy. The city stands in an area called the Multimedia Super Corridor (MSC), which extends south from Kuala Lumpur to Kuala Lumpur International Airport at Sepang. The MSC is being developed to include cities, high-technology office parks, and suburbs, all connected by expressways, a rapid transit rail system, and advanced communications. Plans call for the neighboring city of Cyberjaya to have computer software companies, research and development firms, and a university. Brian J. Shaw

Putty is a filler material that is soft when applied but slowly hardens. It is used to fill knotholes, cracks, and other defects in wood surfaces before the surfaces are painted. Putty is also placed around the edges of panes of glass to seal them in a window sash or door.

The most common putty is a mixture of powdered natural chalk, called *whiting,* and linseed oil, to which a small proportion of coloring agents may be added. Putty hardens because some of the oil combines with oxygen from the air and the rest of the oil soaks into the wood.

Some projects require special, more elastic putty. This type of putty is made from vegetable oil, nondrying oils, driers that make the putty harden, synthetic fibers, a powdered limestone filler, and a coloring agent.

James S. Reed

Puzo, Mario (1920-1999), was an American novelist and screenwriter best known for his novel *The Godfather* (1969). The novel portrays a New York City family involved in organized crime. The narrative describes the family's fight for power against other underworld families in the United States.

The film adaptation of *The Godfather* in 1972 became one of the most popular and acclaimed movies in history. Puzo shared an Academy Award with director Francis Ford Coppola for his screenplay for the film. He again won an Academy Award as coauthor with Coppola of the screenplay for the sequel, *The Godfather, Part II* (1974). Puzo co-wrote the screenplay with Coppola for the third film in the series, *The Godfather, Part III* (1990). He also helped write the screenplays for the films *Earthquake* (1974), *Superman* (1978), and *Superman II* (1980).

Puzo was born in New York City. His first novel was *The Dark Arena* (1955). His other novels include *The For-*

tunate Pilgrim (1964), *Fools Die* (1978), *The Sicilian* (1984), and *The Fourth K* (1991). *The Last Don* (1996) and *Omerta* (published in 2000, after Puzo's death) return to the subject matter of *The Godfather.* Jon L. Breen

Pygmalion, *pihg MAY lee uhn,* was a sculptor and king of Cyprus in Greek legend. Disgusted by the wicked women of his day, Pygmalion carved an ivory statue of a beautiful woman and then fell in love with it. In answer to his prayer, the goddess Aphrodite made the statue a living woman. Pygmalion married her, and they had a son named Paphos.

The legend of Pygmalion has attracted many writers. The ancient Roman poet Ovid retold the story in his collection of tales called *Metamorphoses.* The best-known modern version of the story appears in George Bernard Shaw's play *Pygmalion* (1913). The play tells how an Englishman makes an elegant lady out of an ignorant girl by teaching her to act and speak correctly. The musical comedy *My Fair Lady* (1956) was based on Shaw's play.

Jon D. Mikalson

Pygmies, *PIHG meez,* are small people. The word *pygmy* is a general term for anything small. When spelled with a capital *P*, it usually refers to a member of one of several groups of African people. Most adults who belong to these groups are from 4 feet to 4 feet 8 inches (1.2 to 1.42 meters) tall. This article tells about African Pygmies. Other Pygmies, called *Negritos,* live in parts of Asia and on some islands of the Indian and Pacific oceans (see **Negritos**).

African Pygmies live in thick tropical rain forests. Most live in central Africa, in parts of Burundi, Cameroon, the Central African Republic, Congo (Brazzaville), Congo (Kinshasa), Equatorial Guinea, Gabon, Rwanda, and Uganda. Many scholars believe they once made their homes throughout central Africa. Peoples who speak Bantu languages invaded much Pygmy territory and cut down the forest to grow farm crops and to set up villages.

Today, the Pygmies continue to lose territory because of the construction of roads and towns in the forests where they live. Together, the Pygmy groups have a population of approximately 150,000. In recent decades, the number of Pygmies who follow their traditional way of life has declined at a rapid rate.

Nadine Peacock, Anthro-Photo

Pygmy dancers perform in a small clearing carved out of the dense jungle. Each African tribe has its own symbolic and traditional dances that are passed on from generation to generation.

Way of life. Pygmies have traditionally lived by hunting and gathering. The men hunt antelope, birds, elephants, monkeys, and other animals. Most of the hunters trap animals in large nets and kill them with spears. Some Pygmies hunt with small bows and poisoned arrows. The women gather berries, mushrooms, nuts, and roots. Pygmies also like to eat honey.

Some Pygmies live in small bands of fewer than 50 members. Each band has its own territory in the forest. Pygmies establish temporary camps in clearings, and they build huts of saplings and leaves. A band moves its camp to a new area of the forest when the food supply runs low.

A Pygmy band has no formal leadership. Members of each band make decisions and solve problems by general discussion. Most Pygmies marry people of other bands. Ties of family and friendship link various bands, and a family may leave its band to join another one at any time.

Pygmies speak the same Bantu languages as their crop-growing neighbors. They trade meat to these neighbors for knives and other metal tools and for such agricultural products as bananas, corn, and rice.

Pygmies see the forest as the giver of all life. It provides them with clothing, food, and shelter. In return, Pygmies try not to harm the forest. They perform various ceremonies to maintain friendly relations with the natural and supernatural worlds. Wade C. Pendleton

Pyle, Ernie (1900-1945), an American newspaperman, won a Pulitzer Prize in 1944 for his reporting. His syndicated columns during World War II told millions of Americans how their boys lived and fought as soldiers. Writing with humor and sensitivity, Pyle became one of the best-loved reporters in the United States. He traveled with U.S. troops on nearly every front in Africa and Europe before he went to the Pacific war theater. A Japanese machine-gunner killed him on April 18, 1945, on Ii Shima island during the battle for Okinawa.

UPI/Bettmann Newsphoto

Ernie Pyle

Ernest Taylor Pyle was born on Aug. 3, 1900, near Dana, Indiana. He studied at Indiana University. Pyle worked on newspapers in Indiana, Washington, D.C., and New York City before he became a columnist in 1935. Columns he wrote during the war were published as *Ernie Pyle in England, Here Is Your War,* and *Brave Men.* William McKeen

Pyle, Howard (1853-1911), an American painter, became one of the most influential illustrators of his time.

As an art teacher, he helped develop the talents of such American artists as Maxfield Parrish and N. C. Wyeth.

Pyle combined vigorous draftsmanship with a rich imagination. His sense of pictorial design and his firm, expressive style of drawing has been compared with that of the German Renaissance artist Albrecht Dürer. Pyle's energy and creativity enriched the tradition of American illustration.

The books that Pyle wrote and illustrated continue to attract young readers. They include *The Merry Adventures of Robin Hood* (1883), *Pepper and Salt* (1886), *Twilight Land* (1895), and *The Story of King Arthur and His Knights* (1903). For many years, Pyle illustrated pages in *Harper's Monthly* and drew illustrations for books written by other authors.

Pyle was born on March 5, 1853, in Wilmington, Delaware, and studied at the Art Students League in New York City. He was an art teacher at Drexel Institute in Philadelphia. He died on Nov. 9, 1911.

Marilyn Fain Apseloff

Pyloric sphincter. See **Stomach** (The stomach's work).

Pym, John (1584-1643), an English leader in Parliament, opposed the attempts of King Charles I to rule England as an absolute monarch. Pym declared that "a parliament is that to the commonwealth, which the soul is to the body."

Pym became so influential in Parliament that his enemies nicknamed him *King Pym.* In January 1642, the king entered Parliament with 400 guards to arrest Pym and four others. However, Pym and the others had fled moments before the king and his guards arrived. When the English Civil War broke out in August 1642, Pym formed an alliance with Scotland, which sent troops to fight against the king.

Pym was born in Somerset, England. He entered Parliament in 1621. Pym died of cancer on Dec. 8, 1643, during the second year of the Civil War. Lacey Baldwin Smith

Pynchon, Thomas (1937-), is a leading American novelist noted for his dense style that makes extreme demands on the reader. The difficulty of his works is intensified by the mass of information he pours into his plots as well as shifting narrative points of view and highly technical language and science-based symbols.

Pynchon's reputation rests on only a few novels. Although they typically feature comic, even outrageous, episodes, the works are generally pessimistic in tone. The complex narratives portray modern society in chaos and heading toward destruction. Pynchon's characters often face huge evil conspiracies that may be real or fantasies. Pynchon made an immediate impact on the literary scene with his first novel, *V.* (1963). Among the novel's many plots is a character's search for a mysterious female known only as V. Pynchon's next novel, *The Crying of Lot 49* (1966), is a complicated story about a woman who tries to uncover a secret organization called "Tristero" and its underground communications system.

Many critics consider *Gravity's Rainbow* (1973) to be Pynchon's masterpiece. This huge novel takes place in London at the end of World War II in 1945 and in postwar Germany. It deals with an international conspiracy that dominates the world through missile technology.

Vineland (1990) is a novel set in the 1980's. The story reflects on the counterculture world of California during the 1960's and 1970's. *Mason & Dixon* (1997) is a parody of the English novel of the 1700's, though with many references to the modern day. The novel follows the adventures of the real-life English surveyors Charles Mason and Jeremiah Dixon as they map regions of North America during the 1760's. Pynchon's only other major work of fiction is a collection of short stories published as *Slow Learner* (1984).

Thomas Ruggles Pynchon, Jr., was born on May 8, 1937, in Glen Cove, New York. He graduated from Cornell University in 1959 with a B.A. degree. Pynchon is an intensely private person who refuses to provide biographical information about himself. He keeps his whereabouts secret from everyone but his closest friends. Arthur M. Saltzman

Pyongyang, *PYAWNG yang* (pop. 2,639,448), is the capital and largest city of North Korea. The city is also the cultural, economic, industrial, and military center of the country. Pyongyang lies in west-central North Korea, along the Taedong River. For the location of Pyongyang, see **Korea** (political map).

The North Korean Workers' (Communist) Party, which controls the national government, has its headquarters in Pyongyang. Party leaders in Pyongyang make all decisions affecting North Korea's political, cultural, economic, and social programs and see that they are carried out.

Modern apartment and office buildings line Pyongyang's wide avenues. Pyongyang is the home of Kim Il Sung University. One of the city's principal structures is the large government assembly building, which houses the Supreme People's Assembly, North Korea's legislature. The annual National Fine Arts Exhibition is held in Pyongyang.

Most of the people of Pyongyang work in govern-

Pyongyang is the capital and largest city of North Korea. The downtown area of the city includes traditional Korean architecture, *shown here,* as well as modern skyscrapers.

ment offices in the city or in the factories on the outskirts of the community. Factories in Pyongyang produce industrial goods, such as farm tractors and electric locomotives.

Pyongyang was founded about 3,000 years ago. It was the capital of ancient Korea. The Chinese invaded the city in 108 B.C. and ruled it until A.D. 313. After that, a series of small kingdoms controlled the Pyongyang area. In 427, Pyongyang became the capital of Koguryo, a Korean kingdom that also ruled part of southern Manchuria. Chinese armies destroyed Pyongyang in 668. However, the Korean kingdom of Koryo rebuilt the city during the 900's.

After World War II ended in 1945, Pyongyang served as the headquarters of the Soviet occupation army, which supported the Korean Communists. In 1945, Korea was divided into two parts. Two states, North Korea and South Korea, were established in 1948. Pyongyang became the capital of Communist North Korea. Much of the city was destroyed during the Korean War (1950-1953). However, the city was later rebuilt.

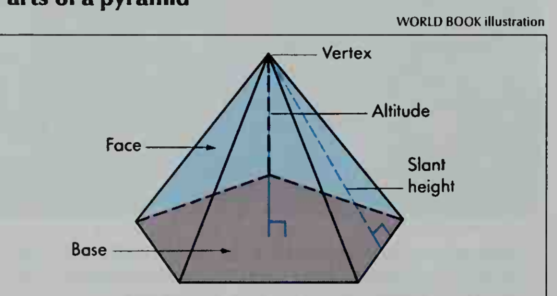
Pyramid, in geometry, is a solid figure with triangular faces that meet at a common point. The base of a pyramid is a *polygon,* a plane figure bounded by three or more sides. The number of faces in any pyramid equals the number of sides in its base. The point farthest from the base—at which the faces meet—is called the pyramid's *vertex.*

In a *regular pyramid,* the faces are all *congruent* (equal in size and shape). Such a pyramid has a base that is a *regular polygon*—that is, a polygon with all sides equal and all angles equal. A perpendicular line extended from the vertex of a regular pyramid meets the base at its center. Pictured here is a regular pentagonal pyramid. Its base is a regular five-sided figure called a *pentagon.*

The *altitude,* or height, of a pyramid is the distance along a perpendicular from the vertex to the base. The *volume (V)* of any pyramid may be found by using the following formula:

$$V = \frac{1}{3}Bh$$

In this formula, B stands for the area of the base and h for the height of the pyramid.



For a regular pyramid, the altitude of any face is called the *slant height.* The formula used to determine the area of the faces *(L)* of a regular pyramid is

$$L = \frac{1}{2}Ps$$

Here, P stands for the total length of the base's *perime-*

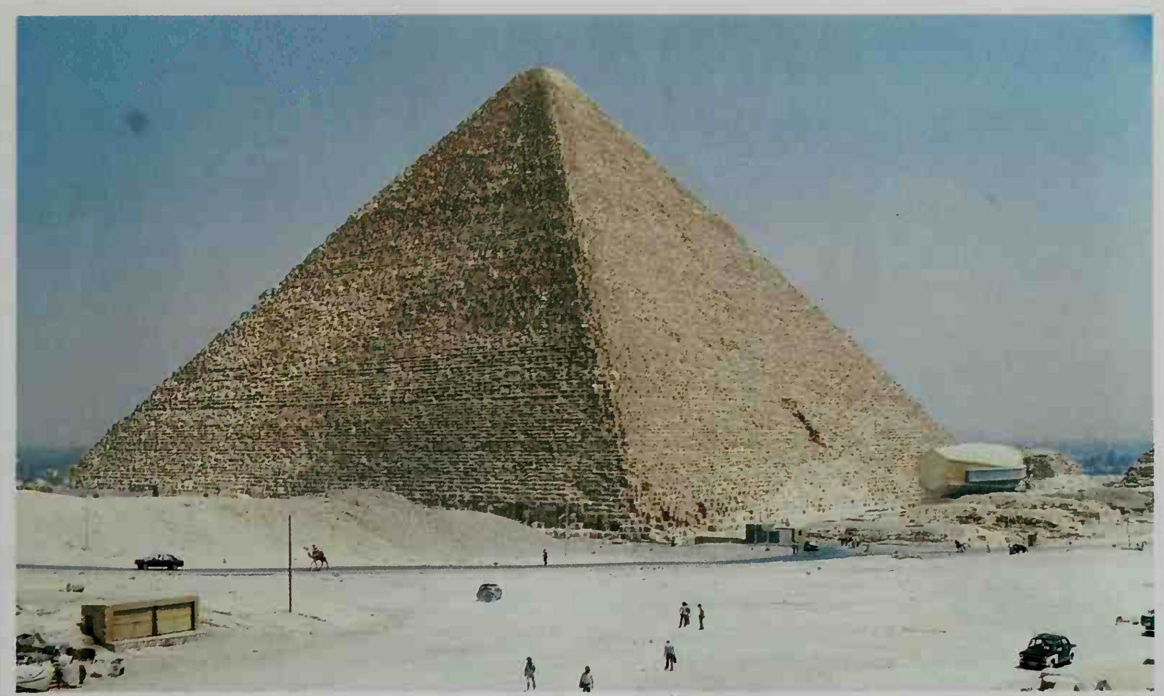
ter (outer boundary) and s for the slant height.

Arthur F. Coxford, Jr.

Pyramids are large structures with square bases and four smooth, triangular-shaped sides that come to a point at the top. Several ancient peoples used pyramids as tombs or temples. The most famous pyramids are those built about 4,500 years ago as tombs for Egyptian kings. These Egyptian pyramids are among the Seven Wonders of the Ancient World.

Egyptian pyramids



The ruins of 35 major pyramids still stand near the Nile River in Egypt. Each was built to protect the body of an Egyptian king. The Egyptians thought that a person's body had to be preserved and protected so the soul could live forever. The Egyptians *mummified* (embalmed and dried) their dead and hid the mummies in large tombs. From about 2700 to 1700 B.C., the bodies of Egyptian kings were buried inside or beneath a pyramid in a secret chamber that was filled with treasures of gold and precious objects.

Many scholars believe that the pyramid shape has a religious meaning to the Egyptians. The sloping sides may have reminded the Egyptians of the slanting rays of the sun, by which the soul of the king could climb to the sky and join the gods.

Funeral ceremonies were performed in temples that were attached to the pyramids. Most pyramids had two temples that were connected by a long stone passageway. Sometimes a smaller pyramid for the body of the queen stood next to the king's pyramid. Egypt has at least 40 smaller pyramids that were used for queens or as memorial monuments for kings. The king's relatives and officials were buried in smaller rectangular tombs called *mastabas.* These buildings had sloping sides and flat roofs.

The first pyramids. Imhotep, a great architect and statesman, built the first known pyramid for King Zoser about 2650 B.C. Zoser's tomb rose in a series of giant steps, or terraces, and is called the *Step Pyramid.* This pyramid still stands at the site of the ancient city of Memphis, near Saqqarah.

The first smooth-sided pyramid was built about 2600 B.C. It still stands at Medum. It began as a stepped pyramid, and then the steps were filled in with casing stones to give the building smooth, sloping sides. Other pyramids built during a period of Egyptian history called the Old Kingdom (2686-2181 B.C.) can be seen at Abusir and Dahshur. During the Middle Kingdom (c. 1991-1786 B.C.), pyramids were built at Hawara, Illahun, Lisht, and Dahshur—near what is now Cairo. The remains of these pyramids are still impressive.

Artstreet

The Great Pyramid, built about 4,500 years ago, rises at Giza, near Cairo.

The Pyramids of Giza (Al Jizah) stand on the west bank of the Nile River outside Cairo. There are 10 pyramids at Giza, including three of the largest and best preserved of all Egyptian pyramids. They were built for kings about 2600 to 2500 B.C. The largest was built for King Khufu (called Cheops by the Greeks). The second was built for King Khafre (Chephren), and the third for King Menkaure (Mycerinus). A huge statue of a sphinx, called the Great Sphinx, was probably built for Khafre. It stands near his pyramid.

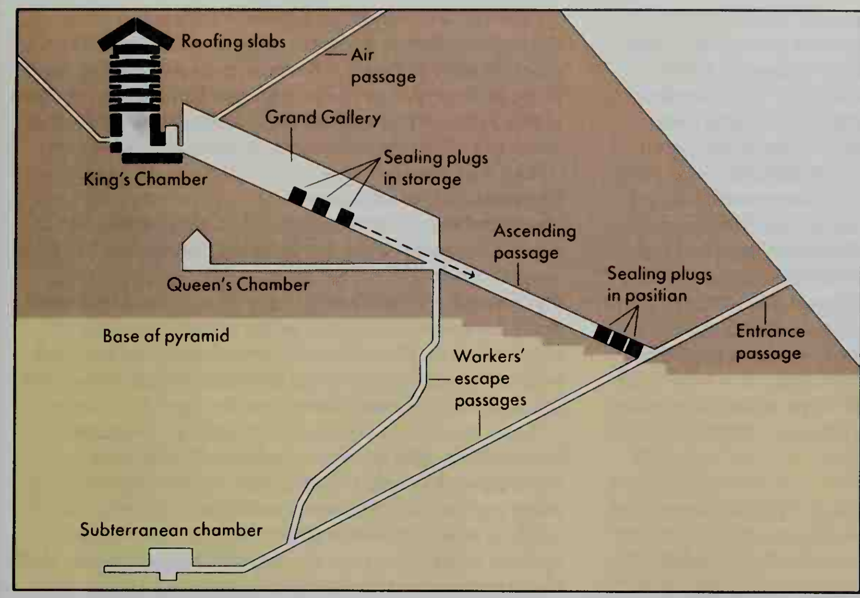
The pyramid of Khufu, called the *Great Pyramid,* contains more than 2 million stone blocks that average $2\frac{1}{2}$ short tons (2.3 metric tons) each. It was originally 481 feet (147 meters) tall, but some of its upper stones are gone now and it stands about 450 feet (140 meters) high. Its base covers about 13 acres (5 hectares).

A study of the Great Pyramid shows how these gigantic structures were built. The ancient Egyptians had no machinery or iron tools. They cut big limestone blocks with copper chisels and saws. Most of the stones came from quarries nearby. But some came from across the Nile River, and others came by boat from distant quarries. Gangs of men dragged the blocks to the pyramid site and pushed the first layer of stones into place. Then they built long ramps of earth and brick, and dragged the stones up the ramps to form the next layer. As they finished each layer, they raised and lengthened the ramps. Finally, they covered the pyramid with an outer coating of white casing stones. They laid these outer stones so exactly that from a distance the pyramid appeared to have been cut out of a single white stone. Most of the casing stones are gone now, but a few are still in place at the bottom of the Great Pyramid.

The burial chamber is inside the Great Pyramid. A corridor leads from an entrance on the north side to several rooms within the pyramid. One of the rooms is called the *Queen's Chamber,* although the queen is not buried there. The room was planned as the king's burial chamber. But Khufu changed the plan and built another burial chamber, called the *King's Chamber.* The *Grand Gallery,* a corridor 153 feet (47 meters) long and 28 feet (8.5 meters) high, leads to Khufu's chamber. It is considered a marvel of ancient architecture.

No one knows how long it took to build the Great Pyramid. The ancient Greek historian Herodotus said that the work went on in four-month shifts, with 100,000 workers in each shift. Scholars now doubt that account and believe that about 100,000 men worked on the pyramids for three or four months each year. Farm laborers built the pyramids. They worked on the tombs during periods when floodwaters of the Nile covered the fields and made farming impossible.

Thieves broke into most of the pyramids, stole the gold, and sometimes destroyed the bodies. Later Egyptian kings stopped using pyramids, and built secret tombs in cliffs. But some kings of the Kushite kingdom in Nubia, south of Egypt, built pyramids long after they were no longer used in Egypt.



American pyramids

Indians of Central and South America also built pyramids. They built stepped pyramids that had flat tops. They used the flat tops as platforms for their temples.

The Moche Indians of Peru built large brick pyramids. *The Temple of the Sun,* near what is now Trujillo, on Peru's northern coast, has a terraced brick pyramid on top of a stepped platform. The ancient Mayas of Central America built pyramid-shaped mounds of earth

WORLD BOOK illustrations by Robert Addison

Building the pyramids was a great engineering feat requiring thousands of workers. First, workers cut and shaped huge limestone blocks using chisels and saws, *above.* Groups of workers dragged the blocks to the pyramid site on sledges and pulled them up ramps on the pyramid, *below.* Planks on the ramps lessened the friction of the sledges. As the pyramid grew taller, workers extended the ramps. Over 2 million blocks were used in building the Great Pyramid at Giza.

WORLD BOOK diagram

A cross section of the Great Pyramid shows the Grand Gallery, the King's Chamber, the Queen's Chamber, and various passages. After the burial, large blocks called sealing plugs were allowed to slide down the passageway from the Grand Gallery to seal off the tomb. Workers left the tomb through an escape passageway.

with temples on top (see **Maya** [pictures]).

Indians of central Mexico also built big stepped pyramids. For example, Indians constructed the great pyramids of the Sun and Moon that still stand at Teotihuacán, near Mexico City. The Toltec Indians built a stepped pyramid at Cholula that is one of the largest structures in the world. The Spanish conquerors destroyed most pyramids of the later Aztec Empire in Mexico. These pyramids were built in steps or terraces like the other American pyramids and had temples on top. Two of the greatest were at Tenochtitlan (now Mexico City). Mound-building Indians of North America built some pyramid-shaped mounds, but they were not true pyramids (see **Mound builders**). Leonard H. Lesko

Pyramus and Thisbe, *PIHR uh muhs, THIHZ bee,* are young lovers in an ancient legend. Pyramus and Thisbe lived next door to each other in Babylon. They fell in love, but their parents would not let them marry or even spend time with each other. They had to talk through a crack in the wall between their houses.

Finally, they planned to meet at night under a mulberry tree outside the city. Thisbe arrived first. She was frightened by a lioness that had bloody jaws from killing an animal. The frightened Thisbe ran away, dropping her veil as she fled. The lioness tore the veil apart with its bloody mouth. Pyramus then arrived and saw the tracks of the lioness and the blood on the veil. He thought Thisbe had been killed and stabbed himself in grief. Thisbe returned to the scene and found Pyramus dead. She then stabbed herself with his dagger.

The Roman poet Ovid told the story of Pyramus and Thisbe in his *Metamorphoses.* William Shakespeare's play *A Midsummer Night's Dream* includes an amateur theater group that performs a comic adaptation of the legend. Elaine Fantham

Pyrenees, *PIHR uh NEEZ,* is a mountain chain that forms a natural barrier between France and Spain. The mountains extend over a length of about 270 miles (435 kilometers), from the Bay of Biscay to the Mediterranean Sea (see **Spain** [terrain map]). They cover an area of over 20,000 square miles (52,000 square kilometers). Their average height is 3,500 feet (1,070 meters), but many peaks in the central ranges rise over 10,000 feet (3,000 meters). The highest point is Pico de Aneto (11,168 feet, or 3,404 meters).

Glacier fields are found on the northern slopes of the Pyrenees. Minerals in the Pyrenees include cobalt, iron,

lead, and silver. The iron mines near Bilbao, Spain, at the Biscay end of the Pyrenees, are a prosperous industry. There are forests of fir, oak, and pine on the mountains.

The Pyrenees chain is a barrier to overland commerce, and France and Spain had to trade with each other chiefly by sea for many years. Several roads now cut through the mountains. Two railways cross them. The first runs between Pau, France, and Saragossa, Spain, by way of the Canfranc Tunnel. The second runs between Toulouse, France, and Barcelona, Spain. This line climbs to a height of 5,200 feet (1,580 meters). There are more than 40 tunnels in a 57-mile (92-kilometer) central section of the Pyrenees. Several resorts are located on the northern slopes of the Pyrenees. The small country of Andorra lies on the south slope of the eastern Pyrenees. The Basques live in the western Pyrenees.

Hugh D. Clout

See also **Andorra; Basques.**

Pyrethrum, *py REE thruhm* or *py REHTH ruhm,* is the name of a group of flowers. Pyrethrums are also called *painted ladies* or *painted daisies.* The flower heads of pyrethrums grow singly or in clusters on erect stems that rise 1 foot (30 centimeters) or more. Pyrethrum flowers look like daisies with pink, white, crimson, or lilac rays. Pyrethrums bloom in spring or early summer, and they are grown as garden flowers or for cutting.

An insecticide is made from the dried and powdered flowers of two species of pyrethrums. This insecticide is also known as *pyrethrum.* In pure form or in a mixture, it is the least poisonous insecticide to animals and people. It is used in liquids, powders, and sprays for insect control on animals, in the garden, and in the home. Kenya is the world's largest exporter of the powder used in making pyrethrum insecticide.

A pyrethrum known as *feverfew* is used as a tonic. A sedative used to treat *neuralgia* (severe pain along a nerve), toothache, and headaches is also called *pyrethrum.* But it is made from the root of a different kind of plant.

Scientific classification. Pyrethrums belong to the composite family, Compositae. The insecticide is made from species with the scientific names *Chrysanthemum coccineum* and *C. cinerariifolium.* Feverfew is *C. parthenium.* The sedative comes from *Anacyclus pyrethrum.* Margaret R. Bolick

See also **Feverfew.**

Pyrite, *PY ryt,* or "fool's gold," as it is sometimes called, is a compound of iron and sulfur, FeS_2. Another name for it is iron pyrite. Pyrite is found in many places and is often mistaken for gold. It can be distinguished from gold by heating it. Real gold will not react when heated, but pyrite will smoke and produce a bad odor. Pyrite is used to make sulfuric acid. The name *pyrite* comes from the Greek word for fire.

When pyrite is struck with a hammer, sparks are produced. In the past, some Indians and members of a number of other cultures used pyrite in order to make fire. Kenneth J. De Nault

See also **Mineral** (picture: Common minerals with metallic luster); **Iron and Steel** (Kinds of iron ore).

Pyromania, *PY ruh MAY nee uh,* refers to an uncontrollable urge to set fires. A pyromaniac experiences tension or arousal prior to setting a fire, and relief or gratification when setting or witnessing a fire. Some pyromaniacs feel sexual excitement from setting a fire. Others experience a release of hostile feelings. Pyromaniacs do not set fires for financial gain or political reasons, or in response to delusions or hallucinations. Pyromania is much more common in males than in females. It usually begins in childhood. Allen Frances

See also **Arson.**

Pyrosis. See **Heartburn.**

Pyrotechnics, *PY ruh TEHK nihks,* is a term used to mean fireworks, or the art of making fireworks. See **Fireworks.**

Pyroxene, *PY rahk seen,* is any of a group of minerals that play an important part in the formation of many kinds of rocks. Pyroxenes occur widely in the continental and oceanic crusts of the earth, as well as in many of the rocks of the moon's outer crust.

Most pyroxenes are the direct product of igneous and metamorphic processes of rock formation (see **Rock** [Igneous rock; Metamorphic rock]). Geologists study pyroxenes that have crystallized from *magma* (molten rock material) and, by doing so, they have learned much about the changes undergone by rocks that have formed from magma.

Pyroxenes range in color from greenish black and reddish brown to colorless. All pyroxenes have the same *silicate structure.* In this structure, a silicon atom at the center with four oxygen atoms attached forms a *tetrahedron,* a pyramidlike figure with four triangular faces. These groups of atoms band together in a single chain, with two of the four oxygen atoms connecting to adjacent tetrahedra. The chains, in turn, are linked together by positively charged atoms called *cations* within the *unit cell* of a pyroxene (see **Mineral** [Inside minerals]).

Cations of different elements affect the arrangements of the chains within the crystal structures. With a calcium, sodium, or other large cation present, the crystals form a *monoclinic* pattern (see **Crystal**). These pyroxenes are called *clinopyroxenes.* With a small cation, such as iron or magnesium, the crystals form an *orthorhombic* pattern. These pyroxenes are called *orthopyroxenes.*

The most common varieties of clinopyroxenes are augites, diopsides, and pigeonites. The most common orthopyroxenes are bronzites and hypersthenes.

Pyrrha. See **Deucalion.**

Pyrrhic victory. See **Pyrrhus.**

Pyrrho of Elis, *PIHR oh uhv EE luhs* (361?-270? B.C.), was the founder of Skepticism. Skepticism was a philosophical movement of ancient Greece. Pyrrho traveled widely and learned many different philosophic viewpoints, each one claiming to be the truth. Because not all viewpoints could be right, Pyrrho decided to suspend judgment about truth, right, and wrong. Custom and convention, he felt, were the only guides to what is just or unjust. Even our senses tell us only how things appear, not what they really are. Pyrrho was born at Elis, Greece. S. Marc Cohen

See also **Skepticism.**

Pyrrhotite. See **Mineral** (picture).

Pyrrhus, *PIHR uhs* (318?-272 B.C.), was a king of Epirus in Greece. His name has lived in the expression "Pyrrhic

victory." It is used to refer to a victory that has cost more than it is worth. The expression arose from a remark that Pyrrhus used after fighting the battle of Asculum in which he lost almost all his men. He exclaimed, "Another such victory and I shall be ruined."

Pyrrhus was a second cousin of Alexander the Great, the king of Macedonia. Pyrrhus was born in Epirus. His father was king of Epirus. However, he lost his throne and was killed when his son was 2 years old. Pyrrhus was put on the throne at the age of 12, but at 17 he lost it. Later Pyrrhus went to Egypt where he served King Ptolemy.

Pyrrhus raised an army and returned to his native country. He recovered his throne and then tried to conquer Macedonia. In 287 B.C., Pyrrhus became king of Macedonia. However, he lost his throne again the following year.

Tarentum, a Greek colony in lower Italy, and its neighbors appealed to Pyrrhus in 281 B.C. for aid against the Romans. Pyrrhus sent 25,000 men and 20 elephants. His forces conquered the Romans, chiefly because of the use of elephants in the battle.

Pyrrhus later helped the Greeks of Sicily against the Carthaginians. In this war, he was successful at first. But he soon began to lose, and finally he was driven out of Sicily in 276 B.C. Two years later, the Romans defeated him and forced him to return to Epirus. The next year, he invaded Macedonia again and once more was hailed as king. In 272 B.C., he marched south and made an unsuccessful attack on Sparta. He was killed in a battle with Antigonus Gonatus while trying to capture Argos.

Ronald P. Legon

Pythagoras, *pih THAG uhr uhs* (580?- ? B.C.), was a Greek philosopher and mathematician. Pythagoras was famous for formulating the *Pythagorean theorem,* but its principles were known earlier. The theorem states that the square of the hypotenuse of a right-angled triangle is equal to the sum of the squares of the other two sides.

As a philosopher, Pythagoras taught that number was the essence of all things. He mystically associated numbers with virtues, colors, and many other ideas. Pythagoras also taught that the human soul is immortal and that after death it moves into another living body, sometimes that of an animal. This idea is called *transmigration of the soul.* It appears in many early religions and is still the belief of many of the Hindu sects of India. Pythagoras may have obtained some of his ideas during travels in the East.

Pythagoras believed that the earth was spherical and that the sun, moon, and planets have movements of their own. His successors developed the idea that the earth revolved about a central fire. This belief anticipated the Copernican theory of the universe (see **Copernicus, Nicolaus**).

Little is known of Pythagoras' early life, but scholars believe that he was born on the island of Samos. In about 529 B.C., he settled in Crotona, Italy. Pythagoras founded a *school* (brotherhood) among the aristocrats of that city. The people of Crotona were suspicious of the Pythagorean brotherhood because its members were aristocrats. The people killed most of the members in a political uprising. Historians do not know whether Pythagoras left the city some time before the outbreak of violence and escaped death there, or was killed in it. The brotherhood of aristocrats was finally destroyed in the 400's B.C.

S. Marc Cohen

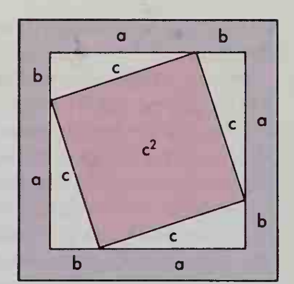
See also **Triangle; Pre-Socratic philosophy.**

Pythagorean theorem, *pih THAG uh REE uhn THEE uhr uhm,* in geometry, states that in a right triangle the square of the length of the hypotenuse equals the sum of the squares of the lengths of the other two sides. The *square* of a number is the number multiplied by itself. A *right triangle* is one in which one angle measures 90°. The *hypotenuse* is the side opposite the right angle. The Pythagorean theorem written as a formula is:

$$c^2 = a^2 + b^2$$

In this formula, c is the length of the hypotenuse, and a and b are the lengths of the other two sides. If you know the lengths of any two sides of a right triangle, you can find the length of the third side.

Origins. The ancient Egyptians wanted fields with square (90°) corners. They had few of the tools we have today. How could they make a 90° angle? About 2000 B.C., they discovered a "magic 3—4—5" triangle. Workmen knotted a loop of rope into 12 equal spaces. They stretched the rope around three stakes to form a triangle. They placed the stakes so the triangle had sides of 3, 4, and 5 units. The angle opposite the side of 5 units (the hypotenuse) measured 90°.



The ancient Babylonians noticed a special characteristic of the numbers of the 3—4—5 triangle. They saw that $3^2 + 4^2 = 5^2$ $(9 + 16 = 25)$. The Babylonians found other groups of three numbers that had this characteristic.

Between 500 and 350 B.C., a group of Greek philosophers called the Pythagoreans came to regard the sides of the 3—4—5 triangle as the sides of three squares. They knew that the area of any square is the length of a side multiplied by itself. Thus, they saw that the area of the square on the hypotenuse equals the sum of the areas of the squares on the other two sides. They also discovered that this relationship among squares is true for all right triangles. They stated this in the rule that became known as the Pythagorean theorem.

A proof. The Pythagorean theorem has had many geometric proofs, but no one knows which proof the Pythagoreans developed. Some mathematicians believe it was a *dissection* proof like the one described below.

In the drawing shown below, the two smaller sides (a and b) of a right triangle together equal the side of a large square. This square is divided into four right triangles, in which c is the hypotenuse, and two smaller, colored squares. The areas of the colored squares are a^2 and b^2. In the drawing on page 922, the triangles have been

rearranged so that their hypotenuses form the sides of a colored square. The area of the newly formed square is c^2. The area of both large squares is the same because each has a side equal to $a + b$. In the two large squares, the triangles occupy equal areas. Therefore, the colored portions of the two large squares occupy equal areas, and so $a^2 + b^2 = c^2$.

Pytheas, *PIHTH ee uhs,* was a Greek explorer who lived in the late 300's B.C. Pytheas slipped by a blockade set up by the Carthaginian navy at Gibraltar in order to explore the northern coasts of Europe. He sailed around Britain and explored that area. He heard of a mysterious land called Thule, which was probably Norway.

Pytheas was a great navigator. He knew that the North Star is not directly above the North Pole. He also realized that the moon has something to do with ocean tides. Many Greek authorities doubted his honesty. However, later discoveries showed that he was telling the truth about the things he had seen. Pytheas was born in Massalia (now Marseille, France). Ronald P. Legon

Python, *PY thahn,* is a large snake that lives in southeastern Asia, India, the East Indies, Africa, and Australia. Some pythons are among the world's largest snakes. The *reticulate python* of southeastern Asia and the East Indies and the *African rock python* may grow 30 feet (9 meters) long. Only the giant anaconda of South America rivals these pythons in length. The *amethystine python* of Australia and the East Indies and the *Indian python* of southeastern Asia and India grow about 20 feet (6 meters) long.

Pythons are called *constrictors* because they squeeze their prey to death. They wind themselves around the victim and tighten their coils. To kill their prey, they squeeze just hard enough to stop the victim's breathing and blood circulation. Large pythons usually eat small animals about the size of a house cat. But they may kill larger animals, such as wild pigs that weigh about 100 pounds (45 kilograms). Pythons swallow their prey whole. It may take a python many days to digest a large victim.

Pythons live in rugged tropical regions that have heavy rainfall and forests, or some type of low, dense growth. Almost all pythons swim and climb well.

Like most snakes, pythons hatch from eggs. The number of eggs in the nest varies greatly. Some may have about 100 eggs. The female python coils around her eggs until they hatch. The Indian python *incubates* her eggs, or keeps them warm with heat from her body. Incubation, which is very unusual in snakes, helps the eggs hatch more quickly. Albert F. Bennett

Scientific classification. Pythons make up the family Pythonidae. The reticulate python is *Python reticulatus.* The African rock python is *P. sebae,* the Indian, *P. molurus,* and the amethystine, *P. amethystinus.*
